An exhibition of spring flowers was held by this society, in the Vestry Hall, Bow, on Thursday, the 4th, and Friday, the 5th of April. The announcement of the fact need not startle the community, but it is worth especial notice that a local society, instituting an exhibition of spring flowers, makes an innovation on the customary order of things, and establishes a most valuable precedent. Not that such an exhibition is a thing unheard of, because in the days of the Surrey Floricultural and other societies, when the late John Neville was a young man, such things were rather common, but they have sunk into desuetude long enough to justify us in congratulating the amateurs of Bow on reviving the idea, and carrying it out with taste and spirit. The large room in which the principal part of the display was made presented a beautiful appearance. So, indeed, did the small room, where there was no competition; but the interest for judges and connoisseurs was concentrated in the competitive part of the display, for there were the evidences of the love of floriculture still influencing the tastes and pursuits of citizens, a matter of far greater importance, socially speaking, than the charming display by Mr. Allen, of the Norfolk Nursery, Shacklewell, who had the small room almost wholly to himself, and made such good use of it, that therein was to be found a complete exhibition comprising plants, cut flowers, and trophies. In the large room there is a sort of orchestra or platform, or rostrum, we know not what: it is a narrow strip of flooring, separated from the body of the hall by an elegant iron railing. It is admirably adapted, on such occasions as these, for a special display of plants, though it may be supposed that on ordinary occasions its use is to favour a display of eloquence; and we trust, if it is ever so used, it may be in favour of a reduction of the present enormous aggregate of metropolitan taxation. Here, however, Mr. Prostoe, the able superintendent of Victoria Park, had taken possession with a splendid collection, comprising *Aralias*, *Marantas*, *Dracenas*, *Caladiums*, *India-rubber plants*, *Eriostemons*, *Begonias*, *Geraniums*, &c., and a very charming variety of colours and forms was the result; all, however, were arranged in a formal manner, befitting the

formal and almost solemn site on which they were placed. On the two sides of the hall were banks of plants and flowers, one large compartment being assigned to Mr. A. Forsyth, of Brunswick Nursery, Stoke Newington, who filled it with *Cytisus*, *Cinerarias*, and other spring flowers, making quite a blaze of colour. Other compartments were appropriated to competitive collections, the schedule inviting competition in collections of plants in flower, and collections of plants with fine foliage. In the collection, Mr. Grovo led the way with a very beautiful group comprising a pair of fine *Callas*, bright *Aecias*, a good example of *Fuchsia Glory of England*, a superbly forced *Hydrangea*, a batch of *Rhododendrons*, a *Rosa* nicely in flower, *Deutzias*, and other good things. In the centre was a little fountain, which splashed and sprinkled most musically, a pretty relief to the stillness of the plants. Mr. Deacon was second in this class with a beautiful group, comprising a very fine and fresh *Hydrangea*, several finely-grown pot *Rosas* (not all of which, however, were out), some brilliant *Cinerarias*, *Dielytras*, and *Fuchsias*. Here again *Glory of England* appeared to be the favourite *fuchsia* for early flowers. Third in this class Mr. Howard, with a fine *Cytisus*, three beautiful *Heaths* in flower, good *Deutzias* and *Hyacinths*, and a few pleasing miscellanies. Fourth, Mr. Hardy, who brought some well-flowered *Pelargoniums*, in which a plant of *Gauntlet* was undoubtedly the best; also *Fuchsias*, *Cytisus*, and a nice lot of *Zonales*. Fifth, Mr. Grace, with a few beautiful *Auriculas*, *Dielytras*, and *Lilies of the Valley*. The judges regretted they could not place this lot higher, especially on account of the *auriculas*, a few of which were exceedingly good; but after careful deliberation, they felt compelled to place them after the foregoing; the sixth position was awarded to Mr. Sinclair, who had some nice pieces of foliage, but not many flowers.

In the class for twelve *Hyacinths* Mr. Grovo took first place with a very beautiful collection. Mr. Grace, Mr. Cheshire, and Mr. Sinclair also presented nice groups, with good spikes and the colours various and fresh. The best twelve *Tulips* came from Mr. Howard; the next best from Mr. Grovo. Here the ugly double *Van Thol* was the best of the varieties, gorgeous for size and colour, but never worthy to compete with a good sample of *Proserpine*, *Tom Moore*, or *Imperator Rubrorum*, which in form and finish vie with the florists' varieties. But double *tulips* please, and therefore have their place in the world. Mr. Deacon presented a beautiful group of six *Polyanthus Narcissus*, very nicely done, the heights uniform, and flowers and leaves clean. In the class for three Mr. Cheshire took first place, Mr. Grovo second.

In the ante-room Mr. Allen of Shacklewell put up a collection of plants and flowers, which were not only displayed with great taste, but comprised a large number of valuable subjects in a state of the highest perfection. A background was constructed by means of a series of painted panels. Against this were placed pedestals surmounted with tree-ferns; beneath the tree-ferns foliage and flowering plants were grouped in two sets, opening in the centre, where was placed a large silver epergne loaded with choice flowers. The effect of this was not only pleasing, but decidedly rich, novel, and above the average degree of merit of such things. We sincerely hope that the amateurs of Bow may, having made so good a beginning, continue to consider a spring show a necessary part of their programme, and that many other societies may follow their example.

Calendar.

WORK FOR WEEK COMMENCING APRIL 13.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Flat-hoe between growing crops, and be very vigilant in keeping down the weeds, dealing promptly with them at every opportunity during dry weather.

POTATOES.—Protect the shoots of potatoes which have made their appearance above ground by drawing earth over them, and continue planting for the main crop.

SEAKALE AND RHUBARB.—Where fresh beds are wanted, they should now be made.

BRUSSELS SPROUTS.—The main crop to be sown this week. It is impossible to ensure fine buttons in the autumn and winter from this much-esteemed vegetable unless the seed is sown early. Choose for the seed-bed a sunny spot, and let the soil be liberally manured. Sow thin.

CABBAGE to be sown in considerable breadths if the main sowing is not yet done. The seed sown now will give supplies from August to April next, if the sorts are well chosen.

CAULIFLOWER.—Those that have stood the winter beneath handlights should have the soil loosened about them, and a little earth drawn to the stems. The glasses should now be removed, but be kept ready to put on at night in case of keen north-east winds blowing, when they will be useful to put on at night, and indeed to leave on for a day or two, should the weather be really wintry, as is not unusual at this time of year.

KIDNEY BEANS may be sown on warm borders for a first supply.

LETTUCES may be sown in open beds for main summer crop. Any that are crowded in seed-pans may be much benefited by pricking out on a bed under a frame, to be lifted shortly with good balls, and planted out finally. If this treatment is carried out with care, so as to cause as little check as possible, some grand samples may be grown, manure and water being of necessity aids thereto. But if the plants are roughly handled, and suffer much, the check will cause them to bolt as soon as warm weather sets in.

BASIL is in great demand in some families, but many never use it at all. It is rather tender, and is best treated as a half-hardy annual, being sown on heat and transplanted. If no convenience to do this, sow on the warmest nook you can find, and if possible on a bed of rather dry sandy soil.

BROCCOLI of any and every kind may be sown now. Any plants coming forward in seed-pans to be made as hardy as possible by full exposure to air and sunshine, preparatory to pricking out.

CARROT.—There is still time for sowing the main crop; in fact, early sowing is not desirable. James's Intermediate is a most useful kind for shallow soils; but there is nothing to surpass *Long Orange* and *Surrey Red* for good deep soils, where handsome roots are required.

ASPARAGUS.—Sow the seed for new plantations on ground deeply dug and abundantly manured. Established beds ought to have been dressed at least a fortnight ago. If not yet done, finish the job at once.

PARSLEY to be sown for summer and autumn use. To grow it fine requires a very rich soil, and the plants to be freely thinned as soon as large enough to handle.

RADISHES of the turnip kind to be sown on rich soil in sufficient breadth to yield supplies for some time. They will not soon get woody if on rich soil, especially if the bed is situated near trees where there will be shade at midday.

CELERY.—Prick out young plants into boxes or on a slight hotbed, and at all favourable opportunities give air as soon as they have established themselves. If the main crop is not already sown, sow it at once in a gentle heat, and also a little of it in the open ground on a warm border to come in late in the season.

Flower Garden.

HOLLYHOCKS planted now will bloom well this season, so there is still time for those who have not yet made up their selections. The soil for *Hollyhocks* should be deep well-manured loam, and the plants should be from cuttings of last autumn, now strong, in 60 or 48 pots, the pots quite full of roots. After planting, turn an empty pot over each plant to prevent exhaustion by the sun, for a week.

PINKS AND PANSIES.—Those should have a rich top-dressing now, taking care to stir the surface of the beds before it is applied.

HARDY HERBACEOUS PLANTS turned out of pots into good borders now will take to their stations immediately. If delayed longer, they will not do so well unless frequently supplied with water; and it is advisable to grow these plants with as few artificial aids as possible.

POLYANTHUS seed may be sown on north borders on fine soil, and to be very thinly covered. If the border is dry, water well before sowing. When the sowing is done, sprinkle a very thin coating of moss over the seed plot; this will preserve a sufficient degree of moisture till the plants appear. If this seed gets dry after being once made moist in the ground, it perishes.

CHRYSANTHEMUMS.—Now is a good time to propagate by means of cuttings, or by taking the young rooted suckers, and potting each singly in a 48-sized pot, and giving them the shelter of a warm greenhouse.

GENERAL WORK.—Look after syringes, garden engines, &c.; put new suckers where required, and see that they are at once placed in efficient working order, as they will speedily be required for constant and active use.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Trees lately planted on dry sandy soils had best be mulched at once with rotten dung. If this cannot be done, spread short litter or some other such material to arrest evaporation, or during dry weather they may suffer considerably. Should there be any pruning not yet done, let it be finished instanter; the trees are growing freely, and in many places pear, plum, and cherry trees are in full bloom.

GRAFTING.—Old trees which it is intended to head down should be done at once, and the stock grafted as soon as possible.

Greenhouse and Conservatory.

GREENHOUSE.—Prepare at once to harden off all soft-wooded plants intended for bedding out early. *Calceolarias* will be all the worse for bedding if kept under glass any longer; the same with *Gazania* and scarlet *Geraniums*, if they have filled 60-sized pots with roots. A few spare lights or old frames will suffice now to protect them at night, and where few facilities exist, a little ingenuity will suffice to provide protection by means of tiffany or varnished calico.

CONSERVATORY.—The surface of the bed should be stirred, and some fresh soil added, in order to maintain the plants in a vigorous condition. Shoots that are rambling and unsightly should be pinched back promptly. Plants placed in the house during their period of blooming should be carefully attended to, and should not have too much water, or they may become diseased. Chinese *Azaleas*, however, require liberal supplies of water while in bloom, but water must not be permitted to fall upon the flowers, and the atmosphere should be kept moderately dry.

PELARGONIUMS required for late blooming should be stopped now, and in such a manner as to make well-shaped plants. Young stock should now have a good shift.

AZALEAS AND CAMELIAS.—Keep shaded while making their new growth, and syringe frequently. Remove all seed-pods and the few remaining flowers that abstract vigour from the new wood. Like ourselves, plants cannot well do two things at a time; when growing, they do not need to be bothered with flowers, and *vice versa*.

BEDDING PLANTS to be exposed as much as possible now night and day during warm weather. Be in no haste to plant, as we may yet have frosts and cold rains. Pot off plants newly rooted, and let them taste a little bottom-heat to induce new roots to form.

CALCEOLARIAS.—Green-fly must be kept down either by means of the syringe or tobacco-smoke. Cuttings taken now and placed in a gentle heat will speedily take root and form nice plants this season. Young stock to be shifted on as required; in repotting, plant deeper than before, as they send out rootlets from the stem. Herbaceous kinds which have been pushed on for early decoration, and are now showing bloom, should be removed into a cool airy place, to strengthen the flower stems, or they will be drawn up lanky and weak.

FUCHSIAS to be frequently syringed, and grown steadily on in a warm moist atmosphere; long-jointed ones may be stopped so as to produce bushy plants.

HEATHS and other hard-wooded plants coming into bloom should have plenty of air.

Stove and Orchid House.

ORCHID HOUSE.—Shade during bright weather with tiffany, or some other suitable material, removing it early in the afternoon. Plants requiring repotting must be attended to as soon as they are fairly in a growing state. Keep up the moisture in the atmosphere by sprinkling the paths, flues, &c., and shut up early in the afternoon. *Cattleyas*, many of the *Dendrobiums*, *Sobralias*, *Gongoras*, *Brassias*, and all similar orchids, must have abundance of atmospheric moisture, as they are now growing freely. The bloom of plants in flower may be prolonged by removing them to the conservatory, drawing-room, or other building where the atmosphere is drier. Plants suspended in baskets or on blocks will require the frequent and plentiful use of the syringe to keep them in health. A more interesting method than using outside shading is to train climbers over the roof; if these are kept in good order, and trained with judgment, they will be found to answer admirably.

STOVE.—Keep up a warm moist atmosphere, and allow no diminution of bottom-heat, as most of the plants, and especially those which have been recently potted, are now making vigorous growths. All free-growing plants,

such as Gesneras and Clerodendrons, should be shifted on as soon as they require it.

SOFT-WOODED PLANTS are now starting into growth freely, and must have light, heat, and moisture. If allowed to start under stages, and in other odd places where they have been stowed away, they will soon get drawn and be the worse for it.

BEONIAS may be repotted and propagated.

GARBIENIAS flourish in a pit with dung linings, as they revel in a warm close atmosphere.

Forcing Figs.

FORCED FRUITS.—Figs will need stopping the young shoots at the fourth eye, and plenty of syringe, to help the swelling of the fruit. Cherries of good size must have plenty of light to give colour and flavour; also syringe, liquid manure, plenty of air, without cold draughts; and as soon as they show colour, less water. Strong foreright shoots to be stopped back to five buds. Peaches and nectarines may have clear weak liquid manure as soon as the fruits begin to swell; at the same time thin the crop, and syringe every morning. All the foregoing may have a temperature not lower than 48° at night, nor higher than 80° by day; keep as much within these extremes as possible, and give plenty of air till two p.m. on bright sunny days.

PINES are growing freely, and must have plenty of water. In the fruiting house there must be a good heat kept up—65° to 70° by night, 80° to 90° by day; successions 5° less. Pines fruiting require more air than growing plants, or the fruit will be flavourless. If the fruit needs support, it is a proof that plants are not so robust as they should be.

VINES in covered borders require the full power of the sun on their roots now, so remove the covering at once. Let there be no neglect in stopping and tying-in, now that the vines are growing freely. Covered borders are usually very dry at this season, and a good soaking is necessary.

CUCUMBERS.—See that the beds are not too moist, or mildew may appear. Add fresh linings, fork up the beds, give air cautiously, stop and train, and use tobacco at the first sight of fly.

FIGS must be frequently syringed until the fruits begin to change colour, and the roots must be aided with manure-water. Stop the young shoots before they push too far; four joints are a good average.

MELONS in a strong state, and with a good bottom-heat, should now be encouraged to set about half a dozen fruit each. If not strong, nip out the blossoms to prevent fruiting. Use the syringe regularly, but moderately; close early. If allowed to go too dry, red spider will appear, and do mischief. If any leaves have a burnt or shrivelled appearance, look underneath them for the cause, where it is likely enough to be found.

PEACHES AND NECTARINES are now coming on well, and the trees must be assisted to swell the fruit to a good size. Give enough water, with liquid manure at least once a week. Pinch off laterals, tie in good wood, syringe early on fine mornings, and always give air early.

STRAWBERRIES ripening to have less water and plenty of light; temperature not lower than 55° by night, nor higher than 70° by day. Remove runners on plants coming into fruit; those gathered from may be allowed to run, to make early plants for forcing next year.

PERIODICALS.

Permanent Pastures: their Formation and Improvement. By MARTIN H. SUTTON, F.R.H.S., &c. 7th edition. Blackie and Sons.—This is the essay originally contributed by Mr. Sutton to the *Journal of the Royal Agricultural Society*, now reproduced for the seventh time, and this time with life-size and truthful figures of the grasses recommended for the several characteristic soils. All we need say of this now famous essay is that it is the best on the subject, and that its appearance in a new dress is most timely and opportune. All who are concerned in the laying-down of pastures should not proceed another step without consulting it.

The Ladies' Treasury, edited by MRS. WARREN, is this month full of life, variety, and its tone throughout is healthy and elevating. There are stories for the young, and essays for those of riper years, and heaps of practical matter for good housewives and housewives who wish to become good. The pictures are admirable: one of them is a large design in colours, representing a fisherman's family "on the look-out" at the sea-beach.

The Gardener for April contains articles on *Hedychium coronarium*, one of the best of the neglected plants; a continuation of the valuable series of papers on "the Flower Garden;" a note on the fruiting of *Benthamia fragrifera*, which will never be of any use in this country; and a variety of other useful and interesting matters.

First Annual Report of the Aeronautical Society of Great Britain. Cassell and Co.—The first sensible contribution to the history of ballooning as a science. It will be valued by meteorologists, and all others who are interested in the investigation of the phenomena of the atmosphere.

The Rail and the Road. No. 1. Great Eastern Railway. By GREVILLE F. (BARNES), 340, Strand.—This is a guide-book for anglers to fishing stations in Essex and Herts, by one of the many accomplished sportsmen connected with our able contemporary *The Field*. To brethren of the angle it will be of great value, as it gives the latest information respecting the regulations of the principal waters, and all needful particulars respecting weirs, pools, shallows, and other matters that directly bear on the quality of the sport in this or that place; and the writer does not forget to point out the best routes to the several districts, and the best houses of entertainment for the tourist angler. It is a good shilling's worth on the subject.

Correspondence.

ROSES AND THE WINTER IN THE WEST.—I have carefully studied the report by Mr. Laxton on roses at Stamford. As an amateur, allow me space for a query or two. In list No. 1 I notice, amongst the hybrid perpetuals, Rev. H. Dombrain, Catherine Guillot, and Comte de Paris. Are not the two former Bourbons, and the latter a Noisette? In list No. 2, amongst the half-hardy hybrid perpetuals, Louise Odier and Baron Gonella. Are not these both Bourbons? In list No. 3, Marguerite Bonnet and Madame Masson. Is not the former of these a Bourbon, and the latter a Noisette? As a young rosarian, I should be obliged if you would put me right. We have had the severest winter here that has been known in this extreme west part of England for above thirty years, yet I find my experience of certain roses differs from that of Mr. Laxton. He puts amongst his list of very tender roses *Comtesse*

de Chabillant, General Jacqueminot, Mademoiselle Bonnaire, Maurice Bernardin, Prince C. de Rohan, Sénateur Vaisse, Eugène Appert, and Anna Alexieff, hybrid perpetuals; and Celine Forestier, a Noisette. All these with me have survived above 10° of frost, unprotected in the open, during the month of January last, and are now, as they have always been, strong healthy plants.

[Rev. H. Dombrain, Catherine Guillot, Baron Gonella, Louise Odier, and Marguerite Bonnet, may be most properly classified with the hybrid Bourbons, but it is really a matter of quite small importance, for many with equally strong Bourbon features are in the H. P. list. Madame Masson is a true H. P., with large crimson purple flowers; but Madame Massot is a Noisette, with pretty flesh-coloured flowers. Comte de Paris is a veritable Tea, a very veritable Tea. The roses you name as in Mr. Laxton's list of tender kinds we have always found to be amongst the most hardy. It is curious that both Mr. Taylor and Mr. Laxton date from damp valleys. We now want reports from bleak hill-sides and hot, stony, dry places.—Ed.]

Replies to Queries.

Selection of Greenhouse Shrubs and Climbers.—R. B.—The following are subjects of easy culture, and every way adapted to the requirements of beginners, being mostly free bloomers offering considerable diversity of character, as to habit and season of flowering. They are also comparatively inexpensive, and obtainable at any respectable nursery. Those marked thus (*) are most desirable for small collections.—*Shrubby Plants.*—**Acacia armata*, yellow, May to June; *A. Lambertiana*, purple, May to June; *A. pulchella*, yellow, May to June; *Adenandra uniflora*, pink, April to July; *A. umbellata*, pink, April to July; **Azalea indica*, in variety, March to May; **Borreria serrulata*, red, June to July; *B. pinnata*, purple, Feb. to May; *Bouvardia tryphilla*, scarlet, April to November; **Csmellia japonica*, in variety, January to May; **Chorozema cordata*, red, April; **C. Dicksonii*, scarlet, July; *Coleonema tenuifolia*, rose, March; *Cytisus racemosus*, yellow, February to May; *Daphne odora*, purple, March to December; *Diosma cupressina*, pink, June to July; **Epacris grandiflora*, crimson, January to June; *E. nivalis*, white, January to June; *E. impressa*, crimson, January to June; **Erica splendens*, scarlet, April to September; **E. grandiflora*, yellow, May to September; **E. aristata* major, scarlet, March to April; **E. Sbanoniana*, white and purple, June; **E. Massoni*, red and green, July to October; *Gardenia radicans*, white, March to June; *Jasminum odoratissimum*, white, May to November; *Nerium splendens*, pink, June to October; **N. oleander*, red, August; *N. album*, white, June to October; *Pultenaea obovata*, yellow, May to July; **Salvia fulgens*, scarlet, May to September; **S. patens*, blue, May to September.—*Climbers and Trailers.*—**Bignonia grandiflora*, orange, July to August; **Cobea scandens*, purple, May to October; *Erythrina crista-galli*, scarlet, May to July; *Gompholobium polymorphum*, yellow, March to August; *Jasminum revolutum*, yellow, March to September; *Kennedia prostrata*, scarlet, April to June; *K. nigricans*, purple, March to June; **Maurandia Barclayana*, purple, April to December; *Lobospermum*, var., July to November; **Mandevilla suaveolens*, white, June to August; **Passiflora cerulea racemosa*, purple, June to October; *Sollya heterophylla*, blue, July to October; **Thunbergia alata*, yellow, May to September; *T. alaba*, white, May to September; **Tropæolum tricolorum*, orange-purple, May to August; **T. brachyceras*, yellow, May to September; **T. Lohianum*, varieties, scarlet, January to December; *T. Jarratii*, scarlet-yellow, June.

TREES IN PARIS.—One of the best features of Parisian gardening, of Parisian improvements, is the great abundance of healthy young trees that are introduced into the very heart of the city, and planted wherever a new road or boulevard is constructed. It is indeed very surprising to see how well this is done, and to what an enormous extent, as well in the centre of Paris, on the boulevards, along the river, &c., as on the scores of miles of suburban boulevards, radiating avenues and roads, the sides of which one would think capable of supplying Paris with building ground for a couple of generations to come. All the planting in all the London parks is as nothing compared to the avenue and boulevard planting in and around Paris; and the trees are nearly all young, but very vigorous and promising. Every tree is trained and pruned so as to form a symmetrical straight-ascending head, with a clean stem. Every tree is protected by a slight cast-iron or stick basket, neat wads and ties preventing this from rubbing against the tree injuriously; it is staked when young, and when old if necessary. Most important of all, nearly every tree is fortified with a cast-iron grating six feet wide or so, which effectually prevents the ground from becoming hard about the trees in the most frequented thoroughfares, permits of any attention the tree may require when young, and of abundance of water being quickly absorbed in summer. The expense for these strong and wide gratings must be something immense; but assuredly the result that will be presented by the trees a few years hence will more than repay for all expense, by the grateful shade and beauty they will afford the town in all its parts. A few days ago we saw them cutting away a new wide street from the corner of the Palais Royal, or from near the Théâtre Français, towards the Boulevard des Capucines, through that very closely-built part of Paris; and as soon as the pathway is levelled, in go the trees and down go their protecting cage and grating, while they are equally busy and far more extensively engaged on the outer side. It is almost too much to hope for such improvement in London, though it is capable of being heightened to an even greater extent by judicious planting, and the trees used in Paris would do equally well there; but we at all events hope that trees may be planted along the Thames Embankment; there will be plenty of space and a fine opportunity, and they would highly embellish what will be the greatest improvement London has yet seen.—*The Field.*

A CREDIT TO THEIR COUNTRY.—A Canadian paper states that there is a family in Trafalgar, near Milton, "raised on clay land," of a length and breadth that the province may be challenged to beat. There are six boys, all over 6ft. high, weighing respectively 219, 220, 224, 220, 217, and 199lbs., making an aggregate weight of 1,300lbs., or an average weight of about 15½ stone.

LEAN SOULS.—A clergyman in Ohio told the trustees of his chapel that he must have his money, as his family were suffering for want of the necessaries of life. "Money!" replied the chairman; "you preach for money!—I thought you preached for the good of souls!" "Souls!" replied the minister; "I can't eat souls; and if I could, it would take a thousand such as yours to make a meal."

The Gardener's Magazine.

SATURDAY, APRIL 20, 1867.

GARDENS IN GREAT CITIES are not always doomed to mismanagement, because we can call to mind a few examples that establish in the most conclusive manner the possibility of city gardening. But, as a rule, whenever the parochial mind initiates a city-garden movement, the end of it is a burlesque of a most melancholy character. Londoners—that is to say, those of them who have any taste and knowledge in gardening matters—must be familiar with some dreadful examples of horticultural muddle in the planting of squares, churchyards, and other open spaces; and many of them can call to mind how ready are city churchwardens to cut down trees, and how reluctant they are to plant them. The Board of Works possesses vast powers, conferred upon it by a recent enactment, for preserving and improving the open spaces of the metropolis. We have not yet become aware that the Board has actually set about cleaning and embellishing any of the metropolitan oases, and we hope that if they should ever put into force the Gardens in Towns Protection Act, they will take competent advice on practical matters, and not go jobbing on their own account, as some of the parochial boards have done, to the waste of parochial money and the disgrace of parochial decency. Such a hideous hole, in the midst of houses, as Leicester Square, is a standing proof that Taste has but small influence in the local affairs of the great metropolis. Even the gardens about the Inns of Court are not all as they should be, or might be; though we must speak tenderly on this point, for we have many times in our hearts forgiven the lawyers for all their real sins, and their alleged sins, when walking through Raymond's Buildings, where the grass is always green, and the elm-trees are protected from butchery; or in the Temple Gardens, where, besides grass and trees, there are also flowers, and occasionally such flowers as attract thousands of persons from all parts to see them. And this very reflection, that the lawyers do more for city gardening than any other class, furnishes the best argument against the churchwardens and members of district boards, who, under the pretence of gardening, do much mangling, but who may perhaps hear to be reminded that what the lawyers find possible other people may find possible, for a knowledge of law is not essential to the successful management of plots of ground set apart as gardens. The prevailing mistake in reference to city gardens generally, is that evergreen shrubs and trees are the most suitable, whereas these, as a rule, are the worst of subjects. There are plenty of deciduous trees and shrubs that will grow as well in a city garden as on the side of a mountain, so far as purity of air is concerned; and the only serious difficulty in city tree-growing is the excessive drainage of the soil: every street and lane in a city has a continuous tunnel for drainage, which takes off the moisture from the soil to such an extent, that trees fond of moisture—as the elm, the lime, the oak, and the beech are,—never can withstand the starvation they are subjected to, and hence are rarely seen in good condition in cities. Nevertheless, something green may be grown, even where the drainage militates against such moisture-loving trees as elms and limes; the Plane, the Ailanthus, the Catalpa, the Cratægus, the Birch, and a host of smaller trees, are as well adapted for city gardens as for plantations in the open country; and we may see in London a sufficient number of examples to render it quite unnecessary to do more than call attention to the fact. The local authorities of Islington made an attempt to embellish the green, once so celebrated as a place for meetings at election times; but in a few years the place became dismal and dirty—a hideous eyesore in a most favourable position for a display of some sort of gardening. The vestry at last took the advice of a practical man, and though Islington Green is by no means what we should like to see, and what we are sure it might be made—a really beautiful garden—it is so bright and cheerful with grass-turf, deciduous trees, and edgings of ivy, that it may well afford a lesson to

all who are interested in such matters as to what may be done, and the errors that are to be avoided in the endeavour. We see there a great success accomplished in the use of Irish ivy, which is so disposed that from every point of view graceful curves of dark green leafage come into view. We see there also a decided failure in the planting of such things as Wellingtonias, Picca Nordmanniana, and Cedrus deodara, for these trees are perishing: the soil is too starving and the atmosphere too smoky for them. But the Pyrus spectabilis, the Almonds, Ailanthus, and even Pawlonia imperialis, have all done well, and of course the Lilacs, Laburnums, and Ribes have also. In Bishopsgate churchyard, to which a correspondent, "Passer-by," called attention in these columns about six months back, the errors of Islington are repeated on a large scale; for the principal furniture of the place consists of evergreens, which are likely to dwindle away; but the Planes and Poplars will probably grow handsomer from year to year, and save the place from looking utterly desolate, when the evergreens have become fit only for heaping on a smother to make charcoal for an onion-bed. It is strange that, although in the "Town Garden" the true principles of city planting were enunciated fifteen years ago, that in these two instances persons who must have been acquainted with that work should make such grievous mistakes. At Islington many of the coniferous trees planted were worth at least five pounds each; and some have already perished and been removed, while others are lingering miserably, and show by their looks that their days are numbered. There is a fatality apparently about the delusion that evergreens are adapted for city gardens, yet every experience proves they are not. Yet, for all that, any and every open spot in a city may be made beautiful by means of vegetation. We say nothing of the removal of the memorials of the dead from Bishopsgate churchyard. Not a stone remains, not one visible proof that the place was for many years—we know not how long, perhaps for centuries—consecrated to the reception of human remains. We suppose the representatives of those who sleep there were consulted, and that the law of the land was not outraged by the proceeding. But we do say that the system of planting adopted is a mistake, and that in due time what now looks so neat and finished will look as if it had been done with a view to another job at a future time.

Let us turn from blemishes to something better. We have referred to the Temple Gardens as evidence that city gardening is at least possible. Now we ask our readers who know those gardens to dismiss from their minds all remembrances of the exhibitions of chrysanthemums held there every year, and judge them by their trees, turf, border flowers, and the rest of the elements that are strictly localized,—and are not those gardens beautiful? Are they not fresh, umbrageous, varied, and inviting? Just as umbrageous, varied, and inviting might be many a plot of ground in London that is now a licensed dust-heap or a mere dead-cat depository. Nor is this all. During the past few weeks the Temple Gardens have been gloriously gay with hyacinths, and the managers of London squares and churchyards have had one more lesson from that most practical of teachers Mr. Samuel Broome. The twelve oval beds adjoining the upper cross walk in the garden of the Inner Temple, where usually in autumn there is a display of pompons, have been filled with these charming spring-flowering bulbs, and the bloom has been rich and substantial—equal every way to anything that has been done with the hyacinth as a bedding plant heretofore. The manner in which this display was produced throws light upon a great question about which gardeners everywhere are concerned, and that is how to secure a good display of spring flowers in the beds devoted to subjects that flower during summer, as these beds are usually occupied beyond the time when it becomes necessary that the bulbs should be planted. Mr. Broome is not one of those who are beaten by small difficulties. He took his time to make his beds ready, and yet started his hyacinths early by planting them in cocoa-nut fibre, under a west wall, in October. There they made abundance of roots, and in January they were lifted and transferred to the beds without injury to a single root-fibre; and the result has been a display of the most delightful and novel character. For such reasons, and because of such examples as we have now submitted to our readers, we repeat, what we have many times advanced in these and other pages, that gardening is possible in cities, and eminently desirable, and there is now no excuse for great mistakes, though in every department of gardening it is necessary now and then to look over little ones.

ROYAL BOTANIC SOCIETY.

SECOND SPRING SHOW, APRIL 13.

This was a small but very interesting exhibition. It was wholly held under canvas, and had had weather to mar its attractions. On either side of the walk down were banks of plants and flowers, and at the extreme end a terminal bank of azaleas, which were, of course, rich with colour, and the principal attraction to the crowd of visitors. No, not exactly so; the principal attraction was a bank of pot roses from Mr. William Paul, done in the best possible style, and shown in the best possible condition, and presenting a very delightful spectacle for visitors of all classes.

AZALEAS.—In the class for three new varieties sent out since 1862 there were many competitors. Messrs. Lane and Son contributed in this class the best Stella in the show, and exemplified that something grand may be accomplished with this variety as a specimen. The flowers were as large and smooth as when Stella was first exhibited; the colour brilliant, and the violet shade on the top petals adding greatly to its splendour. With this, *Elegantissima*, a good white with a greenish shade, and *Advance*, the colour of which is intense rich rosy pink, with carmine on the top petals.—Mr. C. Turner presented *Prince of Orange*, clear red, flowers rather small and compressed, like a Quaker's bonnet; also *Stella*, a large loose plant, the flowers of which were superb for size and smoothness; and *Charles Enke*, lively light pinkish red, with white margins, the colour forming a star on the face of the flower.—Messrs. Ivery sent *Madame Dominique Verveine*, the flower large and flat, with broad petals, colour clear warm flesh, top petals spotted pink; *Souvenir de Prouay*, the form first-rate, colour intense rose pink, the top petals carmine, habit first-rate, and very free; *Flag of Truce*, now well known as a superb double white.—Mr. A. Wilkie, gardener at Oak Lodge, Kensington, put up fine examples of *Etoile de Gand*, the form and substance all that can be desired, colour rose on a white ground, with heavy rose spots on the top petals; *Stella*, admirably done; *Burlingtoniana*, a fine large red.

In the class for six, without respect to age, there were many admirable contributions. Mr. Turner presented a beautiful group, the plants averaging 4½ feet high, and in fine finish. The varieties were *Louise von Baden*, quite a sheet of snowy flowers; *Kinghorni*; *Madame Meiliez*, white, with tinge of green, extra fine; *Etoile de Gand*; and *Variegata* (union plant), *Beauty of Reigate*.—Messrs. Lane sent half a dozen smaller and more precisely uniform plants: they were *Reine des Blanchés*, *Cheloni*, *Magnificent*, *Iveryana*, *Roi Léopold*, *Sir Charles Napier*.—Mr. G. Wheeler put up a group comprising several styles of training: a squat Duke of Devonshire (quite aolid with bloom), *Albocincta*, *Semi-Duplex*, *Broughtoni*, *Stella*, *Marie Louise*.—Mr. Wilkie presented standard plants of *Mrs. Fry* and *Sir Colin Campbell*, and round-headed dwarfs of *Sinensis*, which is always welcome for its colour, and neat pyramids of *Optima*, *Marie Louise*, and *Duc A. de Nassau*.

ROSES.—Mr. William Paul did full justice to himself by his splendid group of pot plants, comprising neat little specimens two feet high and through, and pyramids of four feet high or more, with every intermediate size—just such a group, in fact, as of themselves sufficed to form a picture. As the names of varieties that can be shown in perfection in this way in the early part of April may be useful to many readers, here they are—*Prince de Soria*, scarlet carmine, quite dazzling in colour, and otherwise a charming rose; *Anna Alexieff*, Madlle. Berthe Levêque, *Sénéateur Vaisse*, more inclining to scarlet or vermilion than usual, very brilliant the plant in a 12-inch pot, standing 3 feet high, and 2½ feet through, (with 35 flowers, none of them full out, a charming sight); *Madame Rousset*, a fine large flower, the colour bright rose; *Centifolia Rosea*, extra grand in character, though inclining to the character of *Anna de Diebach*; *Marquis de Foucat*, finely done; *President Mas*, *Fisher*, *Holmes*, superb in colour, which approximates to scarlet, form beautiful, being imbricated like a camellia; *Madame Bod*, a good forcing rose, though rather coarse; *Madame Fillion*, *Celine Forestier*, a fine plant, 4 feet high and 2½ feet through, about 25 flowers, the colour cream deepening to primrose; *Madame Hoate*, *Madame Damaizin*, *Madame Marie Rody*, a large Macaulay-like flower; very fine; *Alba mutabilis*, *Bernard Palissy*, *Glory of Waltham*.—Messrs. Paul and Son, of Cheshunt, presented a beautiful group, comprising *Maréchal Niel* (rich lemon yellow, the best example of it in the exhibition), *Madame Moreau*, *Madlle. Berthe Levêque*, *Madame Victor Verdier*, *Souvenir d'un Ami*, *Pierre Notting*, *Victor Verdier*, *General Jacqueminot*, *Madame Fillion*, *Charles Lawson*, *Madame Willermoz*, *Lord Clyde*, *Madame Caillat*, *Charles Rouillard*, *Madame C. Wood*, *Celine Forestier* (white, with yellow centre, beautiful), *Princess Mary of Cambridge*, *Exposition de Brie*, *Vainqueur de Goliath*, *Alfred Colomb*, *Achille Gonod*, *Fisher Holmes*, *Souvenir de Dr. Jamin*.—A collection of cut roses, from Messrs. Paul and Son, comprised beautiful examples of *Victor Verdier*, *Duke of Wellington*, *Alba Rosea*, *Exposition de Brie*, *Marcella*, *Comte Alphonse de Serenye*, *Baronne A. de Rothschild*, *Sénéateur Vaisse*, *Madame Victor Verdier*, *Maréchal Niel* (a fine example, the colour lemon yellow), *Beauty of Waltham*, *Pierre Notting* (fine), *President*, *Madame A. de Rougemont* (a lovely rose, better doubtless than of pure white), *Duchess de Medina Celi*, *Camille Bernardin*, *Triomphe de Rennes*, *Lamarque*, *Maréchal Niel*, (better colour than in Mr. W. Paul's lot, coming very near to clear yellow), *General Jacqueminot* (atill good), *Madame William*, *Devoniensis* (pale primrose), *Centifolia Rosea*. Messrs. Paul and Son also put up a great collection of cut roses that were aliko delightful for beauty of form and colour and fragrance.

FERNS.—There were several pretty collections, mostly British. Messrs. Ivery, of Dorking and Reigate, contributed of course. The following constituted a group of twelve from this firm: *Asplenium fontanum*, *Blechnum spicatum heterophyllum*, *Polypodium phegopteris*, *Polypodium vulgare Cambricum* (a fine piece), *Cystopteris fragilis angustata*, *Asplenium trichomanes monteii*, *Ceterach officinarum*, *Polystichum angulare rotundatum*, *Scolopendrium vulgare marginata cristata*, and the following varieties of *Athyrium Filix femina*, namely, *pulchellum*, *formosum*, *thyrsanotum*, *cristata*.—Mr. James, gardener, to W. F. Watson, Esq., Isleworth, contributed a nice group, in great part made up of varieties of the *Lady Fern*: they were *Osmunda regalis cristata* (a distinct and handsome variety), *Lustrea Filix mas cristata*, and the following varieties of *Athyrium F. f.*, namely, *stenodon*, *corymbiferum*, *Fieldii*, *vernonia*, *Applehurnum*, *Fissidens excurrens*, *plumosa*, *dareoides*, *conoides*, *multifidum*.—Mr. Bull brought forward several very pretty novelties in ferns: *Athyrium F. f. elegans*, like *Fieldii*, but richer; *A. F. f. goringianum*, curious, coloured, the stipes and rachis purple or reddish, the pinnae reddish

purple half their length, the other half whitish, extremely pretty, and decidedly novel; *Lustrea F. m. Barnesii*, a rich form, the pinnule rounded and overlapping; *Polystichum angulare parvissimum*, a lovely miniature form, the pinnules imbricated; *Athyrium F. f. pulchrum*, a minute *Fieldii* form, rich and fine; *Lustrea varia*, the young fronds cinnamon brown, changing to greenish buff, and ultimately to full green.—From Mr. Ivery, *Asplenium Germanicum acuti dentatum*, more deeply divided than the species, but of little consequence except to extravagant collectors.

One of the finest groups of plants in the tent was a dozen *Spirea Japonica*, from Mr. Bartlett of Hammersmith: they were in 48-size, with fine round green heads a foot over, and three or four spikes each of incomparable snow-white flowers. From the same, a nice dozen *Lily of the Valley*, leaves and flowers exactly balanced.—From Mr. W. Paul, *Crataegus oxyacantha fl. pl. new Scarlet*, a charming double flowering thorn, the flowers like rosettes, the colour vivid rose-pink.—From Messrs. Lane and Son, *Rhododendrons*, *Countess of Haddington* and *Edgeworthia*.

GERANIUMS.—From Mr. W. Paul, three new tricolor varieties: *Red Admiral*, fine bright red zone, in the way of Mrs. Pollock, but more highly coloured; *Rouge et Noir*, dwarf habit, fine dark zone breaking into bars of red, edge yellow; *Prince Silver Wings*, the old leaves like those of United Italy, the young ones like those of Lucy Grieve, a superb and very distinct variety.—From Messrs. Perkins and Son, of Coventry, a brilliant tricolor, called *Queen Victoria*; it is coloured in the Pollock style, the disc dull green, the margin yellow, the zone dark red: this description, of course, gives no idea of the relative excellence of the variety; all we can say is that it is richly coloured, and appears to be a first-rate grower.

STOVE AND GREENHOUSE PLANTS.—Mr. B. S. Williams, of Holloway, put up a pretty group comprising *Yucca aloifolia variegata*, *Cordylina indivisa*, *Genetyllis fuchsoides*, a fine *Croton*, an *Eriostemon pulchella*, and a huge *Azalea alba*. In another group from Mr. B. S. Williams were examples of the lively and most useful *Imantophyllum miniatum*, the characteristic *Bonaparte juncea*, *Dracæna ferrea*, *Todea superba*, *Tetratheca*.—Mr. G. Wheeler contributed a superb *Dicksonia antarctica*, *Hedera macrostegia*, *Eriostemon linearifolium*, *Alcacia metallica*, a *Pandanus*, and an *Azalea triumphans*.—Mr. Wilkie presented *Dendrobium nobile*, *Areca rubra*, *Dicksonia squarrosa*, *Eriostemon intermedia*, an *Azalea*, and a *Yucca aloifolia*.

AMARYLLIS.—Mr. Burley, of Bayswater, put up a handsome group, consisting of *Richard Cœur de Léon*, with two majestic scapes of four flowers each, the petals long, colour intense crimson and lake, with whitish stripe and whitish lines, the atripes change to green in the throat; *Shirley Hibberd*, large, finely formed, rather long petals, colour deep and exceedingly rich, crimson shading to lake, with white lines and greenish rays in the throat; *Meteor*, orange red, greenish throat; *Berangeri*, a small red feather on a white ground; *Comet*, a grand flower with broad petals, clear crimson; *Gordonia*, superb orange red.—From Mr. Wilcocks, gardener to Dr. Pattison, St. John's Wood: *Jupiter*, carmine scarlet, with white stripe and green throat, first-rate; *Venusta grandiflora*, broad petals, clear red, fine; *Hawkinsianum*, carmine, with greenish stripes, fine; *Vittata rubra*, white ground, with comb-like dark red feather; *Ackermannii pulcherrima*, superb crimson and green throat; *Regina*, light scarlet, fine broad segments.

BEGONIAS.—Mr. G. Wheeler exhibited a fine group, comprising *Vanden Hecke*, *Rex*, *Duchesse de Brabant* (in the way of *Rex*, and better), *Miranda*, *Grandis*, *Splendida argentea*.—Mr. Marcham, gardener to E. Oate, Esq., Hanwell, presented *Madame Albert*, a fine gray zone, and dark green star-like disc; *Secretary Morren*, cold silvery gray suffused with a reddish tinge, the edge purplish red; *Grandis*, a fine, hold, broad grayish silver zone, olive margin and central olive star; *Victor Lemoine*, remarkably coloured, the prevailing hue a hard, cold, metallic gray, with grayish olive disc overspread with silver dots—anything or anybody would freeze in front of it on the hottest day; *Marshallii*, very neat, small, striking, colours bright, consisting of silver and rich green. There was another without a name, and if Mr. Marcham will forward the name we shall esteem the favour, as it happens to be a particularly good one; the leaf is large, the disc blackish green, with reddish veins, the zone narrow and broken, very silvery, the margin blackish green.

CINERARIAS.—Messrs. Dobson and Son, of Isleworth, put up a beautiful half-dozen, comprising *Lord Elgin*, a fine magenta self, one of the very best; *Eclipse* (*Lucy*), superb form, broad magenta margin, narrow white ring, dark disc; *Perfection*, narrow rosy purple edge, fine broad white ring, dark disc; *Miss Smith* (*Smith*), fine form and very distinct, broad edge of cobalt blue, shading to rosy purple on the inner side, bold white ring, dark disc—this is one of F. and A. Smith's tricolor varieties, and worthy of all honour; *Conqueror*, fine crimson self; *Admiration* (*Dobson*), style of *Eclipse*, flower rather smaller, and less white.—Mr. J. Fairbairn, gardener to the Duke of Northumberland, at Sion House, put up the following: *Captain Hardy*, not good; *Compacta*, fine; *William Dobson*, same style as *Lord Elgin*, and remarkably compact, with wide-spreading trusses, the plant, in fact, a sheet of colour; *Lady Theodore Grosvenor*, broad cobalt blue edge, clear white ring, fine dark disc; *Creamy White*, very delicate and good of its class, neat brown disc; *Sensation*.—Mr. James, of Isleworth, presented *Fair Maid*, sharp rosy purple margin, broad white ring, small reddish disc; *Wm. Reeves*, broad magenta margin, pure white ring, large dark disc, good compact habit and fine trusses; *Snowflake*, beautiful; *Perfection*, *Lord Elgin*, *Charles Dickens*, one of the best of the broad-edged kinds, rich rosy purple or magenta, and neat purplish disc, good form.—Mr. August, gardener to Rev. S. H. Bridges, Beddington, presented *Adam Bede*, a rich magenta self; *Minnie*, *Captain Schrieber*, a bad self, the colour clear light blue; *Miss Smith* (*Smith*), *Duke of Cambridge*, fine dark crimson self; *Evening Star*, fine crimson purple, white ring, dark disc.

Messrs. Dobson exhibited a seedling called *Beatrice*, the flower large, flat, smooth, the edge clear magenta sharply defined, broad white ring, disc rather indefinite; a handsome flower.

NOVELTIES AND MISCELLANEOUS.—From Mr. B. S. Williams: *Strelitzia species*, deep orange-red bracts, a noble plant; *Glorinia atroviolacea*, beautifully formed, colour carmine, the tube whitish; *Vanda gigantea*, a good example of this now-well-known orchid; *Lindsea cultrata*, a neat usplenium-looking fern, shown under a bell-glass; *Maxillaria species*, an unattractive orchid, the flowers indeterminate but with brown spots; *Dracæna sanguinea*, a very graceful, long-termed species, the leaves linear, dark green, the back of the leaf purplish red, will make a fine exhibition plant; *Oncidium species*, with small yellow flowers, promising.—From Mr. Bull, of King's Road, Chelsea, *Habenaria margaritacea*, a South-American

terrestrial orchid, with broad ovate leaves of a delicate green, heavily overlaid with milk-white spots; *Maranta rosea-picta*, *Iresine aurea reticulata*, a variety of *I. Herbstii*, with yellowish leaves, the veins and stems of which are carmine; *Pittonia argyoneura*, superb ovate leaves, grass-green, overlaid with a multiplicity of white lines; *Tradescantia repens vittata*, very neat ovate leaves, one half of each leaf dark green, the other half almost white; *Nidularium Pinellii*, *Camellia Lavinia Maggi*, flesh overlaid with vermilion stripes, first-ripe; *Camellia Lavinia Maggi Rosea*, clear rosy red, fine.—Mr. Willcocks presented *Odontoglossum luteum superbum*, with one fine spike in perfection; and *Odontoglossum Bluntii*, with two beautiful flowers; this is a good companion to the new *O. Alexandræ*, and like it, though sufficiently distinct.

S. H.

MESSRS. CARTER AND CO.'S NURSERY, FOREST HILL.

The great establishment at Forest Hill, where a considerable portion of the plant-growing business of the celebrated Holborn firm is conducted, is just now in a very interesting condition—in a condition which might furnish occasion for metaphorical expressions; but as metaphor is out of our line, we will be content to say that in all the departments occupied with bedding plants the quantity of stock ready for sale is something surprising. That the many and extensive ranges of houses are crammed, is a matter of course, but so are the hardening beds, or "cradles," out of doors; and for some time past millions of plants, made ready for supplying the first rush of the demand for the season, have been fully exposed to the breeze and the sunshine, but protected at night, and during storms, by means of mats; so that when they reach the hands of customers, they will be as thoroughly hardened as if they had actually been grown from the first in the open air. The object of visiting a nursery is with us solely to gather useful information for our readers, not to utter a puff in praise of anybody. Therefore, as the very first feature of the establishment that we take notice of in entering is the hardening ground, a few words respecting it may be appropriate as introductory to a review of the stock. These cradles are rough frames, nine inches high, enclosing a series of four-foot beds—the length of each is about thirty feet; but length is no matter, as the principle is the same whether the beds are thirty feet or thirty miles in length. The ends are quite closed up; but the sides are closed as required by means of mats. These mats are nailed on rough wooden frames, and when in use they rest on the top bar or "ridge," like the two sides of the roof of a span greenhouse. Mr. Boston, the manager of the nursery, has hit upon a clever method of fixing these matted frames in an instant, so that in the event of a storm they are not suddenly blown all over the place. He has had made a set of heavy V-shaped terra-cotta clamps, which drop on the ridge-bar and clasp both the sides thus:  these clamps look like cast-iron, being of a blackish colour, and they are probably as strong. It is but a few minutes' work, in the event of a storm, for the hands to cover in all the cradles and clap on the clamps, and make all as safe as in a well-built house. You will find a figure of these cradles in the issue for April 23, 1864, but the modes of matting and clamping are amongst the novelties of the season.

Now what do we find in these cradles? Absolutely everything that can possibly be in demand this season for planting out in gardens—Geraniums, Verbenas, Dahlias, Pansies, Calceolarias, Gazanias, Petunias, &c., &c.; their name is Legion. But to see what may be called popular bedders is a matter of course at this time of year. What both surprised and delighted me was to find hundreds of those very plants that have been "written up" in the GARDENER'S MAGAZINE and the FLORAL WORLD during the past few years—those plants of majestic outline, such as the New-Zealand Flax, the hardy Yuccas, the noble ornamental grasses, the Pampas, the *Arundo donax*; the fiery poker plant, or torch lily, *Tritoma uvaria*; ay, even *Crinum capense*; thousands of the lovely varieties of *Dianthus*, thousands of the white Everlasting Pea, cradles full of *Anemone Japonica*, and wide sheets of *Viola cornuta*, and its boon companion *Viola lutea*, with *Delphiniums*, *Dielytras*, *Sedums*, and a fair linear mile of *Echeveria secunda*, which is "coming out" this season as a bedder, and will make one of the most classic edgings ever seen or heard of. From these cradles we find our way to the houses, which, of course, continually increase in number: glass is always growing in a prosperous nursery or well-kept garden. To enumerate the houses would be a tedious affair; their name also is Legion. There are a few, however, that strike the visitor as possessing more than common interest. In the show house there are heaps of *Cinerarias*, *Cytisus*, *Ericas*, *Epacris*, *Azaleas*, *Pelargoniums*, and other flowers proper to the season, with a few pillar plants; amongst them a *Passiflora*, now blooming nicely, and which would very well suit Mr. Hullett, as he might offer it to his patrons, at a guinea an inch, as the stellar passion-flower obtained from one of the fixed stars, *Passiflora cælestis*. The fern houses are crowded with kinds in great demand, the stock of *Adiantum cuneatum* and of *Lomaria gibba* being enormous. The somewhat scarce but beautiful *Pycnopteris Sieboldii* is in plenty here, and there is a good stock of young plants of the noble *Asplenium nidus*, or bird-nest fern, which makes so striking a figure at great exhibitions. The big house that used to be filled with hard-wooded mixtures is now occupied with *Camellias*; and the half-stove adjoining is gay with *Dendrobium nobile*, fine half-specimen plants smothered with flowers. Mr. Boston has fertilized many of his orchid flowers lately, and has now some good pods of seed. *Phalæopsis amabile* and *P. Schilleriana* especially promise to multiply themselves in this way. The principal Geranium house is always occupied in part with young Vines. The same temperature and intensity of light suit them both, and the house is well adapted, by its light, broad, comparatively low roof, to make the very most of the sunshine for the plants. This nursery has always been famous for its Vines, and, by the healthy appearance of the present stock, it may be judged that Messrs. Carter do not intend to lose one jot of their just fame in that respect. The Geraniums in this house number only 60,000 plants, which, of course, is but a portion of the general stock, the greater part having been for some time past out of doors. But it is a pretty sight to see so many occupying a great bed, the whole length of the centre of the house, showing here and there patches or blotches of bright flowers. On a shelf above—that is, a shelf suspended from the roof—were 5,000 fine plants of Mrs. Pollock: these plants are in small 60-size pots, and have six to eight leaves each—beautiful, short, round-headed samples, in brilliant colour—more brilliant than usual, the effect of being kept in the strongest possible amount of light. As for other houses, I forbear to attempt to give any idea of their size, shape, or contents. Mr. Boston, our excellent coadjutor Mr. J. C. Clarke, and the writer of this were engaged some hours in exploring, and probably not one of us could now give a categorical account of the route pursued or the things seen; for we

followed no rule, and mixed up inspections with criticisms, and "sometimes walked and sometimes ran," as did Adam when he first woke from soundest sleep, and became aware of the proper use of his limbs. A summary of things seen may be more useful than a description of the place.

GERANIUMS.—The collection is, as regards varieties, one of the most extensive I am acquainted with, and the system of keeping the sorts true to name is admirable. Amongst the kinds that take the lead, one most deserving of notice is *Christabel*, which is a miniature *Christine*—most valuable for edgings, growing only six inches high at the utmost, and being all through the season quite covered with flowers, which are as richly coloured as those of Helen Lindsay. This was sent out by Messrs. Carter last year, and had a great sale, and, by the immense stock they have of it now, it may be presumed they expect an increased demand this year. In the house containing 60,000 plants there was a batch of this covered with flowers as richly as a bed out of doors might be at the end of June—quite a charming sight to see. Another fine variety amongst Messrs. Carter's novelties is *Crystal Palace Gem*, from the seed-bed of Mr. Gordon of the Crystal Palace. This is the exact counterpart of Smith's Excellent, but the colour is brilliant carise. The flower is of the florists' type, quite circular, smooth, of great size and substance, and most reluctant to produce seed. It will be a leading variety at Battersea Park this season, and will drive out of the field at least a dozen famous old varieties that come nearest to it in colour. And speaking of Excellent, it may be worth remarking that in a cradle containing a batch of *Crystal Palace Gem* and Excellent, with many other kinds, those two were most profusely covered with flowers, while the other sorts were only just pushing their first trusses. *Crystal Palace Beauty* and *Souvenir de Sir Joseph Paxton*, also from Mr. Gordon's seed bed,—the first a charming salmon flower, the second rosy pink,—are decided favourites for this year, and should be put down in the list for present orders by all our geranium growing readers. As for the stock generally, Amy Hogg was showing many cheerful flowers; Beaton's Merrimac was fiery with its peculiar orange scarlet, and there were great breadths of Snowball, a superb white; Wild Charlie, a good deep salmon; Mrs. Whitty, which beats Helen Lindsay as a bedder; *Christine*, still in great demand; Perfection, a fine deep rose-coloured nosegay; Premier, a lovely shade of lilac rose; Rival Nosegay, one of the freest flowering geraniums in existence; and of course Stella, Cybiater, Lord Palmerston, Pink Pearl, and Black Dwarf, which are the cream of the nosegays. Of Hibberd's varieties of last year, H. W. Longfellow wears well as a bright salmon for beds, surpassing St. Fiacre. Kate Anderson is one of the most brilliant scarlets out; but Andrew Marvel, Magna Charta, and May Queen are better adapted for pots than beds, the flowers being of immense size and exquisite in shape and substance. At every nursery now we may see new tricolors; but we may travel far to find a series equal to those Messrs. Carter intend to offer to the public in 1867. Oberon is in the style of Lucy Grieve, the zone broad and hold, varying from vivid red to black, the habit all that can be desired for free growth and lateral extension. *Titania* has a flat leaf with clear amber margin, the zone deep umber brown, breaking into bars of bright red, the disc pure green: this is a splendid variety. *Ruby King* has a small rather convex leaf, the margin primrose yellow, the zone broad, very dark, holdly broken with flame-red; a brilliant piece of colouring. *Miss Schiller* is a heat upon our favourite Luna; the leaf is gold yellow, with a bright cinnamon zone. Mrs. Bass has a large leaf; the colour sulphur-yellow, with broad bright brown zone. These will take a permanent place in the tricolor series, and will have a good chance from the first; for the stock is in a cool house, and has never had the vigour forced out of it in propagating. Before quitting the geraniums, we must notice Goldfinch, which is one of the best golden bedders known, and in many places superior to Luna. Strange to say, that very pretty but unpopular geranium *Reine d'Or* is plentiful here, though what they will do with a beauty that nobody will buy I forgot to inquire. There might be a worse bed or ribbon line than *Reine d'Or* would make for one.

FOLIAGE BEDDERS.—These have acquired immense importance; indeed, leaves are fast superseding flowers in the parterre, and they have the advantage of producing decided effects from the moment the plants are in their place to the moment they are removed for the winter. Moreover, the colouring has unity of tone to commend it; there is no struggle for pre-eminence between the leaves and the flowers. Judging from the extent of the stock, *Iresine Herbstii* (*Achyranthus Verschaffeltii*) is rising in public estimation. It deserves to become a favourite, and will with artists in colour, but will probably never be a favourite with people who only attempt a few commonplace dashes of contrasted colours. It needs the eye of a Gibson to determine its place and proper surroundings; then its rich carmine and bronzy hues, its close resemblance in colouring to *Dracæa ferrea*, are qualities that assure it a high renown. There is a new one here called *Iresine aurea*, which has a richly painted leaf, the principal colour of which are orange, emerald green, and clear carmine. Here also are the best stocks we have yet seen of the three best of the new Brazilian omaranths. *Alternanthera spatulata* is richly tinted carmine and purple; *Alternanthera parymichoides* combines dazzling mixtures of orange and carmine; and *Teleianthera ficoides* is resplendent with carmine and claret lines. Of *Perillas* and *Amaranthus melancholicus* there are tens of thousands of plants; and there are fair quantities of the gorgeous *Coleus Verschaffeltii*, the almost jet black *Coleus nigricans*, and the new dazzling variety of *C. Verschaffeltii*, which has splashes of vivid green and yellow, mixed with crimson on the leaves. The old but good *Dactylis glomerata variegata*, which has become most celebrated of all the variegated grasses, has a formidable rival in the new and beautiful *Poa trivialis variegata*, the appearance of which seen en masse is most delightful, so chaste and pure and brilliant is the colouring, and the habit of the blade as elegant as a grass can be. The *Variegated Japanese Maize* is grown in great quantity, and the plants are now about four inches high, just showing their lines of variegation. This mode of dealing with it is preferred by many persons, as they can have plants from the nursery in which the variegation is already visible, and so make sure of the best forms; whereas if they sow seed, they must take their risk of a few green ones—a risk common to all seedlings of variegated varieties of *Ricinus*, *Solanum*, *Wigandia*, *Ferdinandia*, and other fine foliage plants of the "sub-tropical" class. These are all the best varieties, in such plenty as to press upon us the old question—"Where will they all go to?" But there will be very few of them left by the middle of May; in fact, they are going out now at a terrible pace, though it is full early yet for buying such things. The fact is, people are beginning to take our advice, which is to buy in bedding plants early and keep them in pits, frames, or greenhouses till planting-out time, as by this plan they are

better prepared for planting, and *we know* they are well hardened; whereas, when we buy at the last moment and plant immediately, we *may* happen to put out plants that have not been in cradles, and that consequently are in a soft condition, beautiful to look at, but not yet fit to brave the battle and the breeze.

VARIOUS BEDDERS.—We have not space sufficient to treat of bedders under their several heads, and must therefore rapidly glance at a few in each section. The Verbenas here are as healthy as the tufts of chickweed you will now see, green and flowering, on any sunny bank. The leading sorts agree pretty well with our selection published on the 16th of March last. At all events, there are plenty of the best of the bedding kinds, such as La Grande Boule de Neige and Blanche of Castile, the best of the whites; Mrs. Elphinstone and Ariosto Improved, the best of the rose class; Fire Brigade, and Brilliant de Vaisse, the best of the crimsons; Lord Clifden, Foxhunter, and Mrs. Woodroffe, the best of the scarlets; Junius, the best yellow; Lady Leigh, King of the Lilacs, and Napoleon Rossi, the best of the lilacs; Celestial Blue and Azurea superba, the best of the blues; and Ocean Pearl and Purple King, the best of the purples. As for Petunias, I saw a house full of seedlings that are all to be flowered, judged, and classified before they are sold; a most admirable plan for those who want them in quantities with none of the trouble of propagating, but with certainty as to the sorts of flowers they are to have. Of the named kinds plenty of those charming bedders Royalty, Queen of the Whites, Nemesis, Countess of Ellesmere, Shrubland Rose, and Prince Albert. The GARDENER'S MAGAZINE doctrine, that *small-flowering* petunias are alone fit for bedding, is fast becoming a law in the floral world, and very soon we shall find amateur colourists giving up the great floppy flowers in favour of small, neat, convolvulus-like bells of moderate size, but more plentifully produced, and which can stand against sun, wind, and rain, when the flops would be blown to pieces. Calceolarias are of course very hard by this time. In no well-ordered nursery do they dare push these in heat in spring. At all events, many thousands have long since been exposed to all weathers, night and day, at Forest Hill, and look as short and thrifty as can be desired. That fine old variety Aurea floiuhunda is the leading favourite; but there are good points about Tom Thumb, Canariensis, Bird of Paradise (one of Mr. Williams's best contributions to the parterre), and Prince of Orange; and hence these with others are grown in great quantity. A new Tropæolum, called *Perfection*, has been obtained from the Crystal Palace, and it happens to be one of the Gordon seedlings that we have reported on in our reviews of Crystal Palace bedding. The colour is vivid orange scarlet, the flowers are finely formed, and most abundantly produced. No one need fear planting this wholesale at once, without any preliminary trial; for a tropæolum that is A 1 on the strong clayey loam of Sydenham, where the wind is always strong, and the amount of care bestowed upon individual beds is reduced to the least possible, cannot be otherwise than grand in gardens better situated, or indeed in gardens anywhere; for the Crystal Palace garden is one of the most severe tests to which a bedding plant can be subjected. That gem of white-flowering Lobelias *Miss Murphy* has a most charming appearance now; the stock looks like a great bed of Saxifraga hypnoides, or something even greener than that, dotted all over with snow-white flowers on very short stems, so that the flowers almost rest on the foliage. All that we have said against Lee's Snowflake may be reversed in favour of *Miss Murphy*: it is a gem of the first order, and those who do not buy it lose a season with a plant that will be immensely popular, because it is wondrous good.

MISCELLANIES.—First and foremost among miscellanies must be placed the *Clianthus Dampieri*, of which there are some glorious plants in flower. One of them already covers a great breadth of trellis, and has about fifty heads of flowers, so that in the coming summer there may be as grand a sight here in this way as there was at Wellington Road a few years ago. The white-flowering variety is planted in the same house, but is not yet in bloom. Gnaphalium lanatum, the very silvery-leaved edging plant, is grown in great quantity. Hundreds of Tropæolum tricolorum, in 54-sized pots nicely trained, will be useful to amateurs who wish to grow fine specimens, as by purchasing these they avoid all the difficult parts of the business, and can easily shift into larger pots and train to larger trellises, with all the summer before them for growth. Great stocks of bedding pansies, such as Maggie (now known as Cliveden Blue), Gold Shield (now called Cliveden Yellow), and Purple Banner (now called Cliveden Purple). Scrophularia nodosa variegata, the plant that looks so much like a variegated Hydrangea when bedded out, very plentiful—whole cradles filled with it. Lobelia cardinalis, the much neglected but not forgotten friend of the old school of first-rate plantmen, in abundance here, which is another tribute to the advocacy of good things by the GARDENER'S MAGAZINE and the *Floral World*. There is a good variety of Anemone Japonica here, called *Marie Paré*, the flowers pure white. The aucuba-leaved daisy, richest and rarest of hardy herbaceous gems, in abundance, and as true as the gold with which their lovely leaves are lined. *Sedum Parmenteria* is to be a companion to *Sedum fabarium*, and we have booked it for the plunging system. Carduus Benedictus, and some other things, of what we may call the O'Shane type, in plenty; so there need be no lack of elegant forms in the flower garden, even if the proprietor has but a few shillings to spend upon it. And lastly, Aucubas and Auriculas by alphabetical arrangement come together, though not very much alike, and are here to be found in endless variety; the first having just set their berries as the result of persuasion, the second showing their velvety flowers as the result of being left to take care of themselves, which is one of the secrets of successful auricula-growing. Lastly, and to make an end of the story, Margehal Niel Rose is so much in demand that the side of a long house has been filled with it, and at least a fourth part of the plants have flowers on them. Thus our rosarian friends will learn that the brave Marshal is not ashamed of his epaulettes, but takes care to show them at the earliest opportunity. S. H.

THE DELPHINIUM.

I have always considered it a rich treat to have the pleasure of seeing a good bed of Larkspurs, and I love to see them now, although they belong to the class of plants considered old-fashioned. I am not an old man by any means, still I have a few old-fashioned notions, and one is my adherence to these beauties. I cannot imagine what our poets, both ancient and modern, have been thinking about, not to have tuned their harps to sing the praises of the Larkspur.

I can only account for it in this way, that a nice well-kept garden appears too cribbed and confined for minds which are always soaring in lofty flights, in imagining things that in all probability will never happen. I will not quarrel with them; but I think it a great shame to have neglected my pets. I expect I had better be practical and commence at once. Therefore, in this humble contribution, it will be best for me to say as little as possible about the history of the Delphinium, and also not trouble to inquire from what source it derives both its botanical and common name. Consequently, we will be satisfied with the supposition that the young buds do really resemble a dolphin, and it follows, as a matter of course, that it is legitimately entitled to the generic name of Delphinium. As regards its English, or common name, every body that grows them, and chooses to take the trouble to inquire into the matter, can satisfy themselves upon that point. I consider the perennial species to form as good a class of herbaceous plants as any other genus extant. We have no other blue that can in any way match such as is found in *Formosum*, *Hendersonii*, and others of that stamp; and those Delphiniums which more properly come under the appellation of Larkspurs are quite as good as the generality of annuals. We have the dwarf *D. agacis humile* in half a dozen colours—blue, lilac, purple, rose, striped, and white; then we have *D. hyacinthoides plena*, or hyacinth-flowered, with large heads of bloom, like that of a well-grown hyacinth, in several colours. These vary in colour from the dwarfs by having red and flesh-coloured amongst them, in addition to the other colours. If we want tall sorts in annuals, we must speculate in the varieties of *elatum*, as well as blues and whites and other colours, the same as in the preceding species we get lilac and rose. If those are not sufficient that I have mentioned, there is the *D. consolida*, or branching: for my own part, I prefer the hyacinth-flowered and the branching; but as tastes differ, I thought it best to point out what there are, and let people choose for themselves. Sown in clumps in mixed borders, at intervals of ten to twenty feet apart, in separate colours, they have a splendid effect, and in out-of-the-way places a bed of mixed colours has a charming appearance. They do not continue in bloom long enough to warrant their being used for the planting of beds in prominent positions, or when the bed is part of a design. Ordinary soil will suit them; but, of course, the better the supply of food the plants receive, so much finer and better will the flowers be. The seed can be sown where the plants are to bloom, or in pots to be pricked off. The latter way will make the most of the seed; but as it can be obtained from first-rate houses at the rate of from twopence to fourpence per packet, it is of very little consequence to talk about saving. Seed can also be obtained of most of the perennial species.

I have added the average height to the dozen comprised in this list; it may probably be useful in planting. *Alopecuroides*, four feet, white, edged with blue, fine new kind; *Azureum flore pleno*, four feet, light azure blue, a very fine kind; *Barlowi*, three feet, a most beautiful violet-blue; *Belle Alliance*, three feet, good blue; *Bicolor*, three feet, deep blue, with white centre; *Chinensis*, a foot and a half, light pale blue; *Donkelaari*, three feet, blue; *Formosum*, three feet, beautiful blue, everybody's favourite; *Grandiflorum maximum*, four feet, a most intense blue, superb; this does well in a peat soil, which, generally speaking, Delphiniums do not like. *Hendersonii*, three feet, rich blue; *Ultramarine*, fine large flowers; *Madame Rougier*, two feet, blue. To ensure a good and early bloom, the seed of these kinds should be sown in the autumn, early enough for the plants to get stout before winter; and they can also be increased early in the spring by dividing the old stools. A spit of rotten dung should be dug in when the plants are to be put in. If they are to be turned out amongst the shrubs in beds, let them be well manured and dug deeply. As soon as they have done blooming, the flower-stalks should be cut down. INDEX.

THE WILD FLOWERS OF SPRING.

Come, gentle Spring, ethereal mildness, come,
And from the bosom of yon dropping cloud,
While music wakes around, veiled in a shower
Of shadowing roses, on our plains descend.

THOMSON.

There is something so delightfully charming to the human mind to watch the return of spring, bringing in its train all the hosts of wild flowers. With what pleasurable emotion it causes the heart to throb, as we roam the fields again in all their freshness and beauty, leading the mind instinctively to look up from nature to nature's God; and to be able to gather to our hearts' content the wild flowers which now abound! It wakes up all the old memories of our childhood which long have been lying dormant, under the pressure of the cares of the world. It brings back some of our happiest days of youth, which were spent in searching for flowers in the fields and hedgerows. Wild flowers we dearly love. They have a charm over us which all the flowers cultivated in a garden fail to have. They take us back to the scenes we used to tread in childhood, and in imagination we see the same green fields, and

SUMMER ANTICIPATED.—A GLIMPSE OF THE PLUNGING SYSTEM.

Having occasion to call on our worthy Editor, on some matter of business connected with a flower-show, I was equally astonished and delighted to find myself, on entering the garden, in the midst of a most lovely and novel display of flowers. For the moment the whole affair appeared to me a mystery; it was like being suddenly wafted to a region of enchantment; but a few minutes' observation and reflection ere I attacked his citadel to demand admittance, caused me to ejaculate (I am sure audibly), "This, then, is a sample of the plunging system—most original, most surprising, most superb!" And I dare say you, good reader, would have made a similar ejaculation if you had just leaped out of an omnibus, after several hours' peregrinations in London, and had, by passing through a not very inviting gate, found yourself in the midst of a lovely galaxy of hyacinths, tulips, lilies, crocuses, diolytras, and other spring flowers, all appearing *au naturel*, as if growing in the ground, and all matching their sparkle of colour with a most delicious perfume. The fore-court was like a Rimmel bath, or a realization of Cowper's idea of a blissful place,

Where spices breathe and fragrant roses smile.

I discovered it to be the plunging system by observing that the beds and borders were remarkably clean, and their colour a beautiful dark-brown, which set off the green of the leaves and the colours of the flowers in a remarkable manner. Now I shall endeavour to give an idea of the scene; for though I have read about it more than once, I had no idea at all of its true splendour, and of the truth of the axiom the Editor has more than once uttered, that the plunging system is the system for all suburban villa gardens. Right before me in the centre of the court, I saw what I at first took to be a bed of Japan lilies, edged with hyacinths, tulips, narcissi, and lachenalias. This bed is supported by a handsome stone moulding. What I took at first for lilies proved at a second glance to be crown-imperials superbly grown, with an abundance of brilliant leafage and many shades of yellow, orange, and red-brown flowers. I afterwards learned from our friend that he has a collection of these Crown Imperials comprising some twenty or more varieties, and I saw many distinctions amongst them both as to height and colour, a certain few of the darkest kinds being truly magnificent. This lovely bed, with the blooms of lachenalias lying carelessly over the rim of the stone-work, would have been an ornament to the grandest garden in the country; and I doubt if on the 26th of March, when I made my visit, another such bed could be found in any part of the British Islands—that is to say, *in the open air*. On the left hand of the walk, up a narrow border, also supported by an elegant stone moulding and consisting of cocoa-nut fibre, and again, across the court next the front wall of the house, were hyacinths, tulips, narcissi, fritillarias, double snowdrops, and crocuses in abundance. Those in the little border under the house being such spikes as we only expect to see at flower shows, glorious examples of skilful culture, and displayed as few could display them. The mention of the mode of display reminds me that, in the bijou border next the house, the background to the hyacinths consisted of handsome pot specimens of ivies, beautifully trained, and very rich in their deep green colouring. The background to the other border was a rich breadth of evergreen shrubs, comprising hollies, aucubas, daphnes, rhododendrons, &c. All these were planted out as in any other garden, the plunging being in the front lines only.

My curiosity was as much aroused as my love of flowers was gratified by this display, and I made a few inquiries, that I might indite, for the information of my brother amateurs, these few lines respecting what I now regard as the *perfect* system of garden embellishment, more especially for all gardens in the suburbs of towns. I feel bound to say that Mr. Hibberd explained everything, answered every question readily and cheerfully, and showed me the machinery and material employed in working out the plunging system, which is in operation here all the year round, and demands about thirty sets of plants to keep it going.

The restricted space in which the work is done renders the result something marvellous. I counted four shelves, one above the other, on either side of a little Paxtonian house, the plants actually standing in a perpendicular series, deriving light only aslant, with the exception of those on the top shelves. Yet all were pictures of health and beauty: I know if I were to attempt to grow plants that way, I should lose half of them. A few frames and pits, and a hot lean-to, and a series of plunging beds filled with cocoa-nut fibre, are kept in active service. I noted as leading features among the plants grown the following: a collection of varieties of Ivy, very various and beautiful; a collection of coniferous trees, principally Cedrus Deodara, Cupressus Lawsoniana, Pinus cembra, Abies Douglasii, and Irish yews, with others the names of which I forget; in fact, I know nothing about trees, and therefore could not remember all the names given me. A long row of what I took to be auriculas proved to be Sedum fabarium, which had just been divided, and potted in 48-size. These I was told would be in perfection in September, and would then be of great value for plunging. Next I observed a collection of pompones, not yet touched; they are to be propagated immediately: the principal sorts were Bob, Brilliant, Autumn, Berroll, Salomon, Adonis, Mrs. Turner, Mr. Murray, Mr. Astie, Shirley Hibberd, General Canrobert. These are preferred for their distinct colours, and their requiring comparatively few ties. I was assured that many of the finest varieties were of little use for plunging, on account of their not holding up their flowers well during wind and rain. A lot of nice-looking roses in pots caught my eye, and I suggested that an extemporized rose-show with plunged plants would be a fine idea. I was informed that these had all been used for that purpose, but were now to be planted out to refresh them, and perhaps a fresh lot would be potted to take their place. A collection of Ixias had a charming appearance, so fresh and bright were they, and one or two were already in bloom. A small batch of shrubs in a shady corner were pointed out to me as of pre-eminent value for winter plunging: they consisted chiefly of Skimmias, from which the berries had been gathered and sown. The beautiful Pyracantha is grown in the same way—the trees are quite pictures of symmetry; also several kinds of Cotoneasters. I saw all the new aucubas, including male plants, and was assured that these plants would soon become of the greatest value for plunging, because of their red berries and the splendid leaves many of them have. The true female A. Japonica was pointed out: it was a pretty dark green bush, covered with flowers that had been fertilized. I regret I cannot hope to do justice to the subject on which I have undertaken to say a few words; but I thought the testimony of an amateur, who of necessity views the matter differently to a person engaged in horticulture as a profession, as

Mr. Hibberd is, and led on too by a passion for experiment and inquiry,—that the testimony of such a one to the reality and splendour of the plunging system, would be esteemed by many readers of the Magazine. When I thought I had seen all, and was having a last look at the beautiful ivies, which number some sixty sorts, collected from all parts of the world, it was proposed that I should see some other gardens Mr. Hibberd has, and of which of course I had no idea. I was taken amongst some new houses, then down a plank, and through a brick field into a wild sort of place where no one would suspect there was a garden. But here indeed there appeared to be more matters of interest than I had seen already; for it was the trial-ground on which the collections of peas, potatoes, broccolis, &c., are planted. Here I found a few rows of small plants of scarlet Ribes in a nursery-bed. When they are nice bushes, they will be potted for the plunging system. In the same place was a little batch of a dwarf sort of lilac, which flowers freely in a small state, making large bunches of beautiful blue flowers. Knowing nothing about seakale, asparagus, peas, potatoes, and the rest of the things here, I was glad to get away, though I felt impressed by the order, and I will even say the beauty, of the work, the plots being laid out in the most regular manner; and every collection is numbered all through, and the names, numbers, dates of planting, &c., all entered in a book. The department occupied with the trial peas is arranged so that there is a long row right through the piece at every eight feet distance, and between every two rows is a four-foot bed occupied with such things as broccolis, cabbages, &c. Of course many of the sorts were not yet above ground, but the system was easily comprehended by the pegs in the ground, and the glimmer of greenness where the seeds were coming up.

Supposing I had seen all, I was a little bit astonished when Mr. Hibberd invited me to see his fruit-trees. In a few minutes we were in another garden, not so wild a place as the last; in fact, a very snug spot, and crammed so full of trees that I wondered much more how they could grow than I had previously wondered at the way the shelves were put one above the other in the greenhouses. But there could be no mistake—the trees are doing well, for the greater part of them were showing such a promise of bloom that in a short time their appearance will be splendid. Many of the trees appeared to be all bloom, though none were out. There is in this garden several interesting trees of other kinds—a complete collection of plane-trees, some thorns, and other things of like nature. Mr. Hibberd assured me that he had really brought me here to see the roses, and presently I came to a quarter very irregularly planted, but stuck all over with huge tallies like young gate-posts. On every tally was a number, and nothing more. The meaning of the irregular state of the plants was this: the whole piece had been filled with cuttings of all kinds of roses in October, 1865, and to every batch a tally was attached with a number, so that the names of the sorts could be found when wanted. Some of the sorts had perished outright, and hence so many blanks. Other sorts had all rooted and had grown well, and were now nice little bushes two feet high, bristling with new leaves. This is called the currant-tree system of growing roses, as the cuttings are put in just as currant-trees are propagated. The proportion of those that perish is about a sixth part of the whole, and that can be well afforded, seeing how easily, and, with a margin of a sixth part for loss, how certainly roses may be multiplied in this way.

I trust what is amiss in this short account will be received by the reader with every indulgence. Mr. Hibberd objects, and no doubt properly, to strangers entering his garden; it is a part of his study, and he complains of being intruded upon by persons whose only object appears to be to gratify an idle curiosity, and make waste of his valuable time. But I felt that, having seen so much, I was bound to record my impressions, and I have done so, having the permission of my excellent friend to say whatever I please on the subject. I take advantage of that permission to say another word, and it is a word of great importance. To grow myriads of plants in pots, and make a change in the embellishment of a garden every two or three weeks all the year round, even on the restricted scale on which it is done at Stoke Newington, must be a costly business, and I question if there are many amateurs who really need the system who could afford to carry it out. Why, I am certain many of the hyacinths plunged in the borders, showing better spikes than we ordinarily see at flower shows, must have cost two or three shillings each, for many of them are scarce kinds; and when one particular subject is used in a lavish manner, even if the cheapest kinds only are used, one change is a matter of pounds. Then, it must be remembered, we cannot purchase or propagate plants as Mr. Hibberd can. He can enter the wholesale market, and he can multiply plants like magic, and with his brisk young men, with whom he is at work at all hours directing and arranging, the production of a display is not only a delight after his own heart, but an easy thing; whereas to many of us, lacking both the means and the skill, the thing is impossible. I venture, therefore, with all respect to my friend, to record my opinion that the plunging system will never become general. It demands more skill and more money than can be brought to bear upon it by persons of the middle class, and the rich, I suppose, do not want it. Such is my deliberate opinion from what I have seen. I hope I may be in the wrong, for it would be a grand thing to have our gardens kept as this is; but I feel fully persuaded I am right. What is a reality to our friend must remain a dream to the majority of his readers. J. E. SAUNDERS.

PROTECT THE BIRDS.—At a meeting of the Farmers' Club of the American Institute, Dr. Trimble said that he had recently visited the grounds of the Pennsylvania Hospital for the Insane at Philadelphia, where the good effects of protecting birds are very strikingly exhibited. About fifty acres are enclosed by a high stone wall, and for twenty-five years no one has been allowed to discharge a gun on the grounds excepting Dr. Trimble, who, for scientific examination, has been allowed to shoot two or three birds not to be found elsewhere. In consequence of this protection, all the birds that will live there are found in the enclosure in great numbers. There are cherry trees in the grounds, and when the cherries first began to turn red, the trees were swarming with birds, especially the grackle, or crow blackbird. But they soon became cloyed with the fruit; and, by the time cherries were ripe, had almost entirely ceased to eat them. Dr. Trimble visited the grounds in company with a number of naturalists, and they made a search for worms, but none were to be found; the birds had exterminated them. Two crow blackbirds were shot, and their crops examined; not a fragment of a cherry was found in either, but the crops were filled with water beetles from the neighbouring marshes, showing that the birds had learned to come to this enclosure for protection, even when they were obliged to seek their food elsewhere.—*Scientific American*.

Calendar.

WORK FOR WEEK COMMENCING APRIL 20.

Kitchen Garden and Frame Ground.

BET must be sown now if not done already. Choose poor soil that has been deeply dug, and is in a thoroughly pulverized state, the object being to obtain roots of moderate size and regular shape. All the dark-flesh and short-topped varieties are good.

ONIONS may be greatly benefited by a sprinkling of soot, which will both quicken the growth and drive away the vermin that usually destroy them. Onions for pickling to be sown this week on poor ground. The silver-skinned is generally used, but White Globe is also suitable. Sow thick, and if possible cover the seed with a sprinkling of fine siftings of charred rubbish.

SCARLET RUNNERS may be sown on dry sheltered borders, but it is early yet for the main crop.

CAULIFLOWERS may now be planted out, and will take care of themselves. Let the ground be abundantly manured; plant firm; give a drop of water to each if needful.

SPINACH to be sown again, but not in great quantity, as the later-sown breadths will be liable to get seedy before they are all used.

LETTUCES of all kinds may now be sown on open borders, the cos and quick-growing large kinds of cabbage being most useful.

GRASS LAWNS in need of improvement may be aided by sowing grass seeds. All the bare spots that are mossy and sour should have the surface soil removed, and its place supplied with fresh sandy loam. Places that are thin of grass, but the soil pretty good, may be sown over without any change of soil. Sow thick, and cover the seed with a sprinkling of about half an inch of fine dry earth. It is best to have a sufficient quantity of fine lawn grass seed, and some Dutch clover in addition, and to sow them separately, as they do not mix well. To promote the growth of clover, surface dress with superphosphate of lime during May and June, after mowing. The unsightly appearance caused by spreading this substance is soon removed by the growth of the turf. A sprinkling of half an inch depth will be sufficient at a time. Siftings of plaster and old mortar make an excellent dressing for lawns required to be in good a condition.

CELERY.—Any late sowings now coming on in seed-pans must be pricked out as soon as they are as large as the head of a young radish—say having four or five leaves each. The way to prick them out is to prepare first a frame, next tread the ground hard where it is to stand. On the hard surface lay turfs, grass side downwards, and on the turfs spread three inches of quite rotten dung and fine loam, equal parts, well mixed together. On this bed plant them in rows carefully; water, put on the light, keep shaded and rather close till they begin to grow; then take the light off during the day as much as possible, taking care to put it on in case of cold rains, or snow, or frost, all of which are possible even up to the middle of May. The plants from early sowings that were potted will have to be dealt with according to the weather, and other circumstances. They will soon fill their pots with roots, and when they do so—better, indeed, *before* they do so—shift them into 60-size, with one rather flat crock only in the pot, the soil half dung and half loam, and keep them in a frame, giving plenty of air and water, and exposing them fully to sunshine. By the time they fill these pots with roots, the season will be sufficiently advanced to allow of planting out; and this, like all other processes, must be done with care. The trenches should be made in the usual way, by throwing out the earth. A liberal allowance of fat manure should then be wheeled in, and the soil of the trench well chopped up with it, so that earth and manure are thoroughly blended together. It is astonishing the difference it makes to such plants as celery, cauliflower, and others that need abundance of manure, whether it is turned in anyhow, so as to lie in masses, or well chopped over, and mingled with the soil: in the latter case the growth is regular and good; in the other it is irregular—a plant here abominably coarse, and overtopping the next, which is as weak as if the ground had never been manured at all. For the planting choose warm moist weather, if possible; if this cannot be done, water the trenches liberally the day previous to planting, and after planting water again, and shade from midday sun. In the planting process the line should be put down, and the plants should be handled with as much care as if they were worth a crown each. Let them be turned out of the pots without bruising them; the ball of roots need not be disturbed, the earth must be closed upon them neatly, and while the planting goes on they must not be left laying about in the hot sun, to be half roasted. Those pricked out into the bed should be dealt with in a similar manner; but of course they will not be planted out so soon. In taking them out of the bed, it will be found that as they are well rooted into the turf, the bed itself can be cut into squares or strips; and if these squares or strips are carried carefully to the trenches, the plants may be transferred to their final places without damage to a single leaf or root-fibre, which is the proper way; the plants ought not to know, in fact, or indicate by any of their appearances, that they have been shifted.

Flower Garden.

ASTERS sown immediately will grow freely from the first, and make as fine plants as the earliest sown, though a week or so later to bloom. But this is the latest period for them, to do anything like justice to these superb annuals. The most useful sorts are Truffaut's Paony-flowered, the Chrysanthemum flowered, and the Quilled or German.

STOCKS sown now will give less trouble than those sown early, and the annual kinds will flower well this season, and the biennials acquire strength to stand the winter. The most useful kinds are dwarf German and Wall-flower-leaved Ten-week, English Scarlet Ten-week, English Intermediate, German Emperor, and English Brompton.

AURICULAS require the most airy position possible now, with shade and shelter and covering, as wind, frost, rain, sunshine, and heat are all alike injurious to them. There is no simpler method to deal with them than to stand the pots on a hard pavement of stone, tile, or coal-ashes, and place over them, at some height from the plants, old lights resting on pots, or rough frames made on purpose. In case of frost, mats can be thrown over at all times; there will be a free current of air through, and the lights can be taken off when desirable, and be replaced instantly. Another plan in general use is to place the plants under hand-glasses, the latter being raised very high up.

PANSIES sown now will bloom well at the end of July, when many herbaceous and annual flowers are over. Choose a shady spot for them.

HARDY HERBACEOUS PLANTS which may be raised from seed may be sown from this time to the middle of June. Usually there is at this season so much excitement about hedging plants that these things are forgotten. It is, however, the best season in the whole year to make up lists and order seeds, and, in fact, to begin with their cultivation. It may not be unfair to mention the seed-list of Mr. Thompson, of Ipswich, as full of interest for the lovers of herbaceous plants. Messrs. E. G. Henderson and Son, of St. John's Wood, have published a list of a very select character; Messrs. Backhouse and Son, of York, are rich in such things, and supply catalogues when asked for them; Messrs. Osborn and Son, of Fulham, have a good collection; and, lastly, certain generally useful subjects, such as *Arabis*, *Lychnis*, *Dianthus*, &c., may be found in plenty in *all* seed and plant catalogues.

CARNATIONS AND PICOTEES to have as much air as the state of the weather will allow, and not on any account to suffer through lack of water. As soon as possible place them in their blooming quarters, fully exposed to all weathers.

ANNUALS.—Continue to sow for succession. Half-hardy kinds not yet sown to be got in at once. A top shelf in a lean-to is a good place to bring on a few pots of seeds quickly, but take care they do not get baked there.

THE PHLOX.—The lovely flowers of herbaceous phloxes are distinct from those of all other plants of similar habit in their exquisite symmetry of form and delicacy of colouring. They are for the most part very hardy, though judicious cultivators do not leave their collections entirely to the mercy of the weather all winter. We do not see phloxes as often as we should; amateurs are so crazy about geraniums and verbenas, which many of them cannot manage in a way to be thoroughly satisfactory, that their minds are drawn away from such a subject as the phlox, which is hardy, requires very little attention, and never fails to make an ample return for whatever trouble is bestowed upon it. To grow phloxes, you need a mellow, deeply-stirred, and well-manured loam, and a sunny position. The plants should be set out one foot to eighteen inches apart, according to their height and robustness of habit, all the taller kinds requiring more room than the dwarfs. To propagate them is most easy. The best plants are those propagated from cuttings in March or April, but strong stools may be divided in April or May, and if planted again with care will flower well. Plants that have survived the winter in the ground, or that have been kept in pots, begin to grow in March. The shoots should be cut away when an inch to two inches long, one or two of the lowest leaves removed, and be dibbled in close together in pans or pots, filled with any light sandy soil. A mixture of sand and peat is the best, but it does not greatly matter what it is, if clean and sandy. These cuttings soon root if shut up close in a frame, and kept regularly sprinkled and shaded. The shortest mode of disposing of them is to allow them to grow in the pans till they are three or four inches high, and then to plant them where they are to flower. By this simple method they do well, and occasional watering and shading for a time after planting is, of course, beneficial. But a better plan is to pot them off separately in small pots as soon as rooted, and keep them in a frame till the pots are full of roots, giving them plenty of air, and planting out at last during moist weather. To obtain a fine bloom, occasional watering will be necessary, and liquid manure may be used with advantage. But this trouble may be dispensed with, for if the soil is good, and well manured in the first instance, they only want a little watering for a week or two after being first planted, and for the rest of the season will take care of themselves. When first planted, slugs and snails are very fond of them. To prevent the ravages of these pests, plant with them a batch of lettuce, and while there is a young lettuce left the phloxes will be untouched. When established, vermin will not touch them. Phloxes make a good third or fourth row in the rear of geraniums and other hedders. The older and hardier kinds are superb shrubby ornaments; some of the pure whites, and rose and purple selfs, make huge tufts if left alone for several years, and flower earlier than the choicer kinds which are annually propagated. But for a fine bloom fit for exhibition purposes, the system of annual propagation should be followed, and a luxuriant growth should be promoted by affording them abundance of food. Named phloxes are classed in two sections: the first bears more or less affinity to *P. suffruticosa*, which flowers in July and August; the second to *P. decussata*, which flowers in August, September, and October. As may well be understood, many of the varieties partake pretty equally of the characteristics of both sections. The selection which follows is made to comprise an equal number of each section; but it may be well to add that the late-flowering varieties are those which are in the highest repute. There is great sameness among phloxes, yet in the selection here offered the most distinct kinds only have been taken; and though in many instances the brief descriptions are the same, the varieties themselves differ sufficiently to make them individually interesting, as they are all extremely beautiful, and well adapted to engage the attention of discriminating cultivators.—*Twenty-four Fine Early-flowering Phloxes.*—Abdel de Lepidinum, shaded rose; Abdel M. Khan, white and rose; Addisonii, white, carmine centre; Atlas, light rosy lilac; Colonel Dundas, dark purple; Colonel Maclean, rosy purple, shaded maroon; Countess of Haddington, purple-lake, crimson centre; Countess of Home, white, dark crimson eye; Countess of Morton, pure white; Lady Abercromby, white, crimson eye; Lady Musgrave, white, rosy crimson eye; Lydia, French white, rose eye; Madame Breon, lilac striped; Magnet, shaded peach; Magnificia, shaded white, violet eye; Miss E. Spedding, white, crimson eye; Mr. Hollandre, white, pink eye; Mr. Lithgow, shaded rose-puce; Mrs. Bald, silvery white, crimson eye; Mrs. Gillon, silvery white, pink eye; Pearl, French white; Princess, deep peach; The Bride, white, light rose eye; Volcano, dark rose, red eye.—*Twelve Fine Early-flowering Phloxes.*—Duchess of Hamilton, white, rose eye; Duchess of Sutherland, white, dwarf, very fragrant; Marbroe, white, purple eye; Mrs. Buttar, white, shaded pink; Mrs. Collins Wood, white, rose eye; Mrs. Sinclair Wemyss, white, shaded rose, very fragrant; William Elder, rosy purple, dwarf; Clio, white, pink eye; James Niven, rosy purple; Mrs. Russell, white, rosy purple eye; Cormack Brown, white, rosy purple eye; Lady Margaret Wellwood, white, crimson eye.—*Twenty-four Fine Late-flowering Phloxes*, suitable for a first-class border.—The following average eighteen inches high: Baron de Bar, blush, and carmine eye; Felix Forard, rose, pencilled white; General Brea, bright red, and dark eye; Laurelia, white, striped violet; Leodame, rose, and white eye; Madame Boucbarlet, white, and lilac eye; Madame Fontaine, white, red eye; Madame Gouvain St. Cyr, peach, carmine eye;

gather the pale primrose from the same banks, with the same joyous hearts, and are led for a time to forget the world, its gold and tinsel, and to think of higher and holier things.

To me the meanest flower that blows can give
Thoughts that do often lie too deep for tears.

WORDSWORTH.

Amongst the first of the wild flowers of spring the Violet stands prominent, coming, as it were, to prepare the way for others, regardless of the cold winds and cutting sleet. How exquisite is the perfume! Long before you can find out its hiding-place, you know it is somewhere near by the sweet scent that fills the air. What a modest retiring beauty it is, peeping up beneath the masses of its lovely foliage,

That strew the green lap of the coming spring!

Our woods are now covered with that lovely little flower the Wood Anemone, or flower of the west wind. Its delicate white or blush-coloured blossoms must make it a general favourite with all who love spring flowers; then there comes the Wild Hyacinth, with its pure blue bells—it used to be a great favourite with me when a child, then known to me by its common name of "Blue-bottles," and always held a place in my nosegay. Primroses,—the lovely pale primrose, so beautifully and strikingly described by the Bard of Avon,—Cowslips, and other plants of this genus, may be gathered in great abundance from the sunny hill-side and hedges.

Now in my walk, with sweet surprise,
I see the first spring cowslip rise.

MONTGOMERY.

Well do I remember what an exciting affair it used to be with us in hunting for the Oxlip, and with what an amount of anxiety it used to be brought home and planted in our little gardens, with the roots covered with soot and turned bottom upwards, firmly believing in that old belief that goes among children, that the next year it would come up one of those lovely dark Polyanthus; but, alas, our expectations were never realized. There are the lovely Periwinkles, with their starry blossoms of ethereal blue: it always seems as though they had borrowed their colour from the sky. I never see the Periwinkle but I think of the Primrose—the pale yellow blending so harmoniously with the pale blue. *Oxalis acetosella*, or Wood Sorrel: this pretty little flower must be too well known to require anything to be said in its favour; it is one of the most attractive flowers of our woods, its pearly white blossoms streaked with pink veins, and its leaves are of so fresh a green that the herbage around it looks quite dull by comparison. I must not forget the Daisies and Buttercups, and because they are so common disdain to give them a little space; they are beautiful gems, springing up everywhere—

Coming in the spring-time,
Of sunny hours to tell.

Then there are the Daffodils, with their large golden heads nodding to the passing breeze.

We have also the elegant blossoms of the Sloe, or Blackthorn: much has been said in the praise of it; it is usually considered to be the harbinger of warmer weather. Then the Hawthorn, which we should sadly miss for the decorating of the maypole. I do not think there are any wildings which give a more beautiful perfume, and certainly none present a more truly magnificent appearance than an old tree with its tortuous stem, making it look as if it were ready to break down under its immense load of pearly white blossoms. It is indeed a rich treat to sit, on a warm sunny day, beneath its shade, and inhale the delicious fragrance of its myriads of snowy flowers, and listen to the hum of the bees sipping the nectar from them. Oh, how glorious is the spring! Who is there that does not feel glad to see the cold, bleak, and dismal winter die, to give birth to the beautiful spring? What new life it seems to impart, and how it fills our hearts with that deep feeling of gratitude to the Creator, who flings such countless blessings around us! Surely there can be but few who are incapable of appreciating the beauties of this season, for the whole earth seems suddenly to have awakened into new life: the trees are bursting into bud, the hedgerows, and in fact everything, seem as though they were all with one accord proclaiming, "God is good," and proving most truly the great and infallible truths of Holy Writ, and speaking clearly to our hearts and intellects, that "while the earth remaineth, seed-time and harvest, and cold and heat, and summer and winter, and day and night, shall not cease."

FAUST.

A PAPER OF ODDS AND ENDS.

EVERYTHING GOOD *versus* A FEW THINGS WONDERFUL.

A few days ago a well-known practical gardener said to me, "It's a great pity there are not more papers treating on the individual growth of particular plants, and that by persons who are famous

for competing at our horticultural exhibitions." So far the observation may be correct; but we who contribute our mite to gardening literature have to remember, that the majority of those persons who keep a gardener or gardeners do so that they may derive home enjoyments in their garden, and are not always so particular about the size, style, or shape of a plant; but the freshness created by the constant changes presented to their view is of much more importance, and this can be always maintained by treating nothing as too insignificant for our notice, so long as it contributes to the useful in gardening. At this season of the year there is no lack of flowers for making the greenhouse and conservatory look gay. Azaleas and Epacris are being fast succeeded by the Pelargoniums, in all their glowing but various shades of colour. But ere the month of July has gone the pelargoniums will have fulfilled their part for this year. Of course Fuchsias will not have then passed their best; still we shall want other plants to keep up the interest. Now there are a number of plants in every way suitable, when grown in pots, for that purpose, but which are overlooked as unworthy our attention, partly on account of their cheapness. In respect of Balsams, Globe Amaranthus, and Cockscombs, their worth as tender annuals is well understood by all the fraternity of gardeners, so as to need no remark from me; but there are other subjects that claim our attention besides the latter, which will more than compensate for the trouble bestowed on them.

PHLOX DRUMMONDI.

We will begin with Phlox Drummondii and its varieties. These are raised from seed sown in February. When they have vegetated, and are strong enough to be handled, they should be pricked off rather thickly into wide-mouthed pots or pans, and then put in a close frame till they have afforded signs of beginning to root freely. When they have completed sufficient growth to begin to crowd each other, then carefully remove them, singly. If you can take them up with a little earth adhering to their roots, so much the better. I transplant them into 48-size, four plants to a pot. These, by being syringed and grown quickly, will, with staking, make some pretty pots of brilliant-coloured flowering plants, for mixing with *Lilium lancifolium* and *Zonale Geraniums* during the autumn months. They are excellent to cut from, because among them are some distinct self-colours, including white, red, and purple, and other shades innumerable. They must not be allowed to get dry, or they will very soon become infested with red spider. Having more than I required last year for pots, I planted a number of them thickly on a vine border, the surface spit of which was rich with manure. They grew fast into thrifty plants, presenting a fine show of bloom, from which I used to cut and come again, till the frost blighted their beauty.

ASTERS.

Here is another class of plants, especially the *Dwarf Pyramidal Bouquet* variety. They are well adapted for being cultivated in pots, and have a very fine effect when in flower. Give them plenty of pot room and rich soil. The *Ranunculus-flowering German Aster* is also very suitable, and has a very neat appearance when in flower, looking somewhat like a *Pompone Chrysanthemum*. A first-rate plant to cut from, on account of the number of flowers it presents, and the length of their individual stalks.

SINGLE FLOWERING PETUNIA.

The parterre is in general considered the proper sphere for these varieties of plants, and the double sorts for pot culture. But with all that, I always make it a rule of purchasing and sowing in the spring a packet of about six assortments. These, as soon as they are up and sufficiently strong, are treated in every way exactly as the Phlox Drummondii, excepting that, should they grow freely, I pot them into larger pots, and train them to a neat trellis made of flower-sticks. Among the high coloured flowers the effect is charming when in bloom, owing to the mass of flowers they present at one time.

THUNBERGIA ALATA.

How few care to grow this pretty, free-blooming, climbing annual, and what can be the reason why? I think I can solve the question, *i.e.*, this—the seed is vegetated, the plants are well up in the seed pot; but what follows? Why, being at a very busy season of the year, when most gardeners are doing their best to provide for the planting out of the flower garden, then it is the Thunbergias are allowed to remain undisturbed, partly from want of room, and partly from lack of pots. Then it is they become starved, and a ready prey to the attack of the red spider; whereas if potted as soon as they require it, and subjected to a warm humid atmosphere, with a good use of the syringe morning and evening, then do these desirable plants grow and flower freely, and if trained to a medium sized trellis, they make quite a change among other plants in the house during the autumn months. There are several varieties of *T. alata*, and all are good.

ICE PLANTS.

Mesembryanthemum crystallinum, the "ice plant," ought to be more extensively cultivated than it is, especially where there is much fruit grown, on account of its fitness for garnishing the dessert, and also for packing some of the better kinds. The past generation of gardeners paid some attention to the cultivation of it in pots—so much so that in most gardens of any pretensions you would generally meet with some well-grown examples in pots. The best way to proceed, where there prevails a demand for garnishing, is to pot them singly into 60-sized pots, and when sufficiently rooted to transplant them into a well-prepared bed of soil, about four feet wide, on a south border. If it has a slope, so much the better. As the branches grow, strew a good thickness of short grass for them to lay on; this will keep them clean and free from grit, and also preserve a genial moisture to their roots. In sowing cover the seed slightly with a little silver-sand. As soon as they appear above ground, remove them to a warm dry part of the pit or house; for should you continue to keep them in a moist atmosphere, very few will survive.

LOBELIA ERINUS SPECIOSA.

Quantities of this useful plant are now grown true from seed for bedding purposes, &c., but it looks superb when grown in 48-size or five-inch pots, for furnishing the conservatory during the autumn months, or for standing along the edge of a terrace-walk, or in any other similar position, or if suspended in baskets. Now is the time to select a few from among the stock, and pot them on for the purpose.

LILIUM AURATUM.

In trimming some roots of this beautiful lily, a short time since, some of the scales dropped among some cocoa-nut fibre refuse, and, when turning it over yesterday in the cucumber house, I found a single one throwing out a number of rootlets, thus confirming Mr. Prosper's assertion, in his admirable paper on this noble plant, that it could be increased from single scales. I have at least one hundred Gloxinia leaves, which I inserted in the fibre about three weeks since, now forming bulbs and rooting freely.

JOHN F. M'ELROY.

EVERLASTINGS.

Most of the poets who have taken the endless beauties of Nature for their theme, have sung more or less to the praise of these singular and beautiful plants, which have the peculiar property of retaining for an indefinite space of time, after the blossoms are gathered, the beauty of their flowers, which has made them almost, if not quite, universal favourites with those who take both pleasure and interest in those gems which Nature has so abundantly studded our greenhouses and gardens with. I shall not indulge in poetical quotations on this occasion, in justification for any word of praise that I may in the course of my remarks bestow upon them, but rather confine my observations to the cultural part of the business, which is a matter of some importance. Under the head of Everlastings, there is a great number of plants, very dissimilar in their habits, requiring very different treatment from each other, and extending in their native habitats over a vast geographical range: some species requiring the shelter of the greenhouse, with careful attention bestowed upon them to ensure good specimens; others requiring merely a little attention in the early stages of development, and then, in ordinary soils and situations, the cultivator will have an abundance of flowers for in-door decoration through the cold and cheerless months of the year, when vegetation is at its lowest ebb, with nothing to enliven the out-door scene with colouring matter but the berry-bearing shrubs.

I will first of all introduce the greenhouse kind, and begin with the *Aphelaxis*, for it accords with alphabetical arrangement, and, moreover, is one of the very best that we have under this heading. I cannot bestow unqualified praise upon it; for I should say this genus is one of the most difficult to grow that we have amongst the hard-wooded plants in the greenhouse; it bears but little rough treatment or neglect; but very few times of getting too dry, or a few extra soakings of water beyond the proper requirements of the plant, will most assuredly send it to the home from whence no traveller returneth; but when well grown, it is most unquestionably a glorious thing, and stamps the grower as a master hand. The soil best suited for it, or rather what I have found it to succeed best in, is thoroughly good peat and plenty of sharp silver-sand—nearly one part of sand to three of peat—and a few finely broken potsherds: preference should be given to peat with the fibre divided from the roots of heather, for it is much better than when it is principally composed of decayed moss and brake roots. The peat should be chopped up carefully, to prevent the loss of a particle of fibre. It is quite useless to attempt to grow this genus, and expect any amount of success in its cultivation, unless they are potted in really good stuff. First of all, in potting, the pots must be well drained with crocks broken small—say, for

example, to the size of hazel nuts. It does not do to use drainage the same as for common soft-wooded plants. Some of the roughest part of the peat must be put immediately over the drainage, to prevent its getting choked up. If the plants should happen to be any way pot-bound, the roots should be carefully disentangled without breaking them, to enable the young roots to push freely into the fresh soil. They must also be potted sufficiently firm to prevent the water draining through without wetting the old ball. I have known plants to die through that cause. The collar of the plant should be elevated very slightly above the level of the soil, to give it greater facilities to resist any tendency to decay at the base of the stem. All the plants should be repotted sufficiently early to give them ample opportunities of getting established before winter sets in, otherwise the soil will probably get sour, and consequently injurious to the plant's welfare. The plant in question is propagated by cuttings of the half-ripened side-shoots, taken off with a small heel attached, and inserted in sandy peat, with a layer of sand on the top, and covered with a clear bell-glass, and placed in a warm corner of the house. At best it is a bad thing to propagate, and very slow in forming roots. I should recommend the young plants to be bought in from the nurseries.

The undermentioned kinds are all first-class, and can be depended upon: *A. humilis grandiflora* is a beautiful rosy purple; *A. macrantha purpurea*, a fine dwarf-habited kind, with lovely large purple blossoms; *A. rupestris grandiflora*, fine large rosy crimson flowers. These three are really good, and after the culture of them is thoroughly mastered, the list can be added to with decided advantage.

Another very splendid everlasting which I have down on my list is the *Phænocoma prolifera Barnesii*. The style of this plant is peculiar and pretty, and the habit of it quite distinct from the other plants. The flowers are rosy crimson, large, and similar in shape to the preceding genus. It is one of the best and most telling plants for collections of stove and greenhouse plants at late exhibitions. This and the *Aphelaxis* will succeed under similar treatment. Both require to be grown in a light airy house, for they are impatient of being kept in a close damp atmosphere; whilst, on the other hand, they must not be exposed to cold and cutting draughts. If want of space renders their being put out of doors in the summer imperative, the plants must be sheltered from all heavy showers, or quick work will soon be made of them. I should advise their being kept inside if possible.

Before leaving the greenhouse, I must not forget the lovely *Statice Holfordi*. The flowers are produced in immense corymbs of an exquisite blue colour. It is a very handsome plant when in bloom, and the flowers are very valuable for mixing with the other Everlastings, being quite distinct in shape and colour from the stary kinds. The flowers are, moreover, very durable. I have a little branch lying before me as I write that I made a present of seven years since, and it appears nearly as fresh as the day I gathered it: most certainly it has been preserved with jealous care, and, as it is now an object of great veneration, I had better say no more about this particular branch. A soil half loam and half peat, with plenty of sand, with similar treatment to the others, will suit it.

Amongst the out-door Everlastings we have *Acroclinium roseum* and *A. album*, two beautiful half-hardy annuals from the Swan River. They have a neat compact habit of growth. The seed of these sown in March in a little heat, and potted on in some rich soil, not too close, will make nice plants for the conservatory in the autumn. It is not too late now to sow them. If not wanted for in-door work, they should be turned out into the borders as early in May as the state of the weather will permit. The *Helichrysum* presents a very important group, and is indispensable when vases of any size are to be filled, or wreaths made. Four good varieties are the white, rose, scarlet, and yellow. It is much the best to keep to a few really distinct kinds. When the convenience of a frame or a house is not obtainable, they may be sown in the open ground, early, where they are to bloom. The *Rhodanthe* is really a beautiful genus, and all the varieties are worth growing. First we have *R. maculata*, a superb flower, ray-florets crimson, with yellow centre. Then for whites there is *R. maculata alba*, similar in growth to *maculata*, with the same coloured disc as in the flower of that kind; but the ray-florets are a pure white. This is one of the best white Everlastings. Lastly, we have *R. atrosanguineum*. This species has a more dwarf habit and longer foliage than *maculata*. The flowers are of the most beautiful purple. I prefer sowing these in-doors in a little heat, and transplant to their blooming quarters. These also make very good pot plants. Among the yellows none beats the *Waitzia*. *W. acuminata* and *grandiflora* are the best. These are hardy, and can be sown in the open border with every prospect of success. We now come to the *Xeranthemum*. *X. atropurpureum* is a fine double kind; colour, as its name denotes, dark purple. *X. album plenum*, a beautiful double flowered white kind. In gathering the flowers for winter, they should be cut in dry weather and just as they open, but before they actually are open.

GEORGE GORDON.

Madame Rollison, dark rose; Madame Hantin, peach, and white eye; Marquisant, rose, striped eye; Orientale, bright crimson; Rêve d'Amour, peach, rose eye; Triomphe de Twickell, rose, striped white.—The following average twelve inches high: Alice Allain, white, and pink eye; Can didissima nova, white; Comte de Chambord, white; Henri Lierval, red-purple; Jeanne Rouillard, blush; Léon Corbay, red-rose; Madame Itendatler, white, and lilac eye; Orientalis, dark red; Primuleflora, white; Vice-President Adam, red.—*Twelve Fine Late-flowering Phloxes.*—Anne Boleyn, cream and pink, dwarf; Apollon, purple, and rose eye; Bourbonnensis, lilac, varying to white; Cedo Nulli, bronzed salmon; Fulvie, pale rose, white eye, dwarf; Hebe, lilac-peach, and dark cherry eye; John Salter, blush, striped rose; Le Lion, lilac, tipped purple; Louis Lierval, red-salmon; Madame Girardeau, pale blush, dwarf; Napoleon III., deep rose, striped; Princess Alexandra, white, crimson eye.

Fruit Garden and Orchard House.

APRICOTS.—Wall-trees are showing good crops this season, and must be freely thinned. At the same time, every curled leaf must be examined, and the villainous worm that causes it to curl must be destroyed.

FRUIT GARDEN.—The cool moist weather of the past few weeks has been of great service to trees planted late, but unfavourable to established trees coming into bloom, and in many instances plums and wall-fruits have set badly. Very little can be done by the cultivator to assist out-door fruits at this season, but the fruit garden must not be neglected. Pruning is of course completed, and nailing too we should hope. Trees newly planted may require stakes to prevent them being rocked about by wind. Wall-trees will require to be freely disbudded, but only a skilful hand should be set to such work. The object of disbudding is to remove all useless buds at the first start, to lessen the after-labour of pruning, and to prevent the gumming that too often follows pruning with the knife; also to save the trees the trouble of producing shoots that are not wanted. Never thin any tree severely at one time; if there are many shoots to remove, let it be done in several operations, so as not to cause any serious check to the flow of the sap. Raspberries not yet mulched should have two or three inches of fat manure spread over the ground as far as their roots extend. Trees under protection to have plenty of air, but do not remove the material yet.

STRAWBERRIES in the open ground are growing freely. If they have not been manured, it is yet time to benefit them by spreading a thick coat of good manure between the rows, and treading it down firm. As manure is generally scarce just now, Standen's Gardener's Friend, which is the best of all artificial manures, may be spread sufficiently thick to make a gray surfacing on the ground. As this, however, is a rather expensive preparation, we can only advise its adoption in small gardens, where a few fine strawberries are wished for from plantations of limited dimensions.

Greenhouse and Conservatory.

CAMELLIAS not yet started into growth *must* have assistance now, if no more than keeping rather closer and more moist than usual. But much better to raise the temperature and syringe frequently. The earlier kinds that flowered before Christmas, and have now completed their growth, must have less water, more light, more air, but must not be hardened too suddenly, as the weather is cold yet for them while forming their blossom buds.

CINERARIAS want abundance of water now; if allowed to be dry for any length of time, the lower leaves will turn yellow and fall. To make the most of plants, that are showing fine heads, and which are in other respects good, give them a shift to next size pot, but without breaking the ball. Give plenty of air when weather allows, and shade only when the sun is very powerful.

FUCHSIAS require shifting on; keep them warm; give plenty of water at the root and overhead; let the soil be rich and light, the position rather shady; do not allow them to stand in a draught, and stop where they are growing freely. Never stop and repot at the same time.

PELARGONIUMS showing their trusses will be greatly benefited by weak doses of clear soot water, or cow-dung water. Tie out carefully as required, never neglecting this operation, as if the shoots get hard before tying, the operation is apt to snap them. Shade as little as can be helped; the sunshine acting now on the advancing buds will ensure brilliantly coloured flowers, which will not be the case with plants that are much shaded during the formation and growth of the buds. Scorching must be prevented by ventilating freely during bright weather. But better to shade a little than have the plants scorched; however, the remark above is "Shade as little as possible." Syringing is not good for rough or soft-leaved varieties, but those with hard leaves will be benefited by it. All our first lot of blooming plants that have been gay since February have lately been cut down, and set aside in a shady house to break again. When they start we shall give them a shift, and then allow them to grow as they like for autumn bloom. Gauntlet and Brilliant submit to this treatment admirably, and furnish two useful crops of flowers within the year.

Stove and Orchid House.

STOVE PLANTS are in most cases growing freely, and a good heat must be kept up, with sufficient atmospheric moisture. Our seasons are short and dark for tropical plants, therefore the cultivator must make the most of the summer before him by promoting a free and early growth of every plant that should be growing now. Shift, train, and stop whatever requires either of those operations, never delaying an hour longer than can be avoided needful attention when the time has come for it.

ORCHIDS of many kinds are now growing freely, and a moist atmosphere and generous temperature are imperatively needed. Shading must be used, but should be removed about three o'clock in the afternoon, and not drawn down again before eleven next morning.

Forcing Pit.

CUCUMBERS in bearing to be kept as nearly as possible at a uniform temperature—a difficult matter with such variable weather as we have now. Air-giving must be regulated by circumstances: the really careful cultivator will shift his lights half a dozen times a day as bursts of sunshine, driving showers, or cold whistling winds succeed each other. The careless cultivator will have his plants half blown away at times through leaving the lights down too long, and at other times quite burnt up through not giving air when needed. The results of these several modes of treatment

may be guessed at. Fork up the beds, and apply linings if necessary; and as air-giving is a pretty safe operation now, the heat may be allowed to rise to rather a high pitch—much higher than would have been safe a month ago, when it was often impossible to give air. Many cottagers are now making up their beds for a summer supply, and will depend for plants on the generosity of gardeners. We trust all our professional readers have a few strong cucumber plants in pots to give to their neighbours who are neither rich to buy nor skilful to raise such things.

CHERRIES changing colour to have as much light and air as possible, and less water at the roots. Gross shoots may be better checked by stopping once or twice than by hard cutting back, which only results in another growth as rank as the first. Search wherever the leaves appear curled, and deal promptly with the cause of curling.

MELONS must have all the sunshine possible, and to prevent scorching give plenty of air during midday hours on very fine days. Plant successions, taking care to make good beds for them, as with plenty of heat at command a little air may be given night and day in mild weather, and a free strong growth secured without any forcing. Do not not be afraid to syringe melon plants over the leaves; a little of it on fine mornings is good until the fruit is swelled, and it tends materially to keep down red spider.

PEACHES in the early houses are swelling fast, and the final thinning must be accomplished without delay. Give a good soaking of water at the roots, and from this time till the fruit begins to show colour use liquid manure freely. Syringe regularly twice a day, and if possible with water that has stood in the house some time first. Keep a good heat now, and give air freely—50° at night, 75° to 90° by day, with sun-heat.

STRAWBERRIES must have abundance of light and air, and a decidedly cool temperature by night as compared with the day temperature—say 65° day, 50° to 55° night. Renew the dung in the pans, if you suppose they have by this time taken all the goodness from it. Where they have rooted into a bed of dung—a very good plan, of course—leave them alone; they cannot be doing better. Be attentive to binning the fruit, if quality is a matter of the least importance. Remove runners as fast as they are produced until the crop is off, when a few runners will be useful to furnish early plants for forcing next year. In many places the first lot of runners are now rooted, and almost fit for removal.

VINES.—The various attentions requisite as to assisting growth, bloom, and fruit, as vines begin their seasonal work, have been described at some length in calendrical notices during the past two months, and we refer readers to the various notices, requesting them to apply to their own particular cases the instructions given. Vines in cool vineries and on walls are growing now, so it is too late to prune, and not a good time to plant. Bunches formed will want thinning. Muscats must have a good heat. Grapes colouring, no matter of what kind, plenty of heat and a free circulation of air, and less syringing.

HORTICULTURE AT THE PARIS EXHIBITION.

The year which is to witness the crowning attempt of the Emperor Napoleon in behalf of peace and concord has already commenced. We begin to reckon the weeks that must elapse before the inauguration of his magnificent project, while time—*inexorable tempus!*—rapidly diminishes the fleeting hours. Among the many novelties connected with this gigantic undertaking, not the least important is the Exhibition of International Horticulture. This interesting department has been partially developed on numerous other occasions, and, in fact, there is not a park, public or private, which does not contain many specimens of rare and valuable exotics. But a brief description of the prominent part it plays in the forthcoming Exhibition will demonstrate that it has at last obtained that degree of attention and consideration which it unquestionably merits. The display of international horticulture will take place in a reserved or special garden separated from the rest of the park by an iron railing. Those who are familiar with the position of the Botanical Society's Gardens in Regent's Park will be at no loss to form an accurate idea of the case in question. It is bounded by the avenues of Labourdonnaye and Piquet, by the principal walk of the Park, and by the circular railway. Its area is rather over 70,000 square yards, and the main entrance faces the junction of the two avenues alluded to. The price of admission will be half a franc, and no further payment will be required in any part of the garden. There is a point connected with the arrangement of the admission into this garden which, unless it is altered, visitors will do well to bear in mind. Suppose a person already in the park wishes to view the garden, he pays his half-franc and passes in; but if he does not care about seeing the garden, he pays no more than the sum he has already paid for entrance into the park. Now, a person entering the garden from the exterior—that is, by an entrance which does not open on the park—will be obliged to pay not only the half-franc for admission into the garden, but also the sum for admission to the rest of the Exhibition, whether he wishes to go there or not. Thus, if a visitor had seen the Exhibition, and wished to pay a visit specially to the Horticultural Garden, he would have to pay over again for what he had already seen and might not wish to see again. This unwise arrangement, which we hope never to witness carried into effect, will cut two ways: in the first place, it is manifestly unjust, and, secondly, it is a trap to catch the unwary, as many will probably enter by the garden entrance, and have to pay their half-francs without caring to see the garden at all.

Entering by the avenue of Tourville, a splendid panorama bursts on the view. Not a vestige of the Exhibition building or its numerous appendages is visible, but the limpid surface of a vast lake relieves the verdant hue of the expansive sward. From the centre of the former rises a lofty mass of superincumbent rocks, surmounted by a cascade, which in its never-ceasing flow restores to the lake the waters to which it owes its life. The sward is crowned by a small crystal edifice constituting the Winter Garden, and appropriated to the reception of exotics. On each side of this building are formed two artificial gorges or ravines, at the end of which the ground rises, and on the level spaces are a couple of greenhouses, surrounded by ponds filled with aquatic plants. The entrance to these gorges is guarded by masses of rockwork, and embellished with lakes and cascades, while through the falling spray can be dimly seen the gloomy mouths of grottoes and caves, alike inviting the curiosity of the visitor, and by their sombre appearance forbidding him to gratify it. Towards the right of the house devoted to the orchids stands a large semi-circular building with an elegant colonnade and portico. It is the diorama, and is a peculiar feature of the Exhibition, and was invented by M. Rouzzi. As it was impossible to collect all the known plants of the world in one spot, a number of photographs,

amounting to 4,000, of the most interesting specimens were obtained in different lands and forwarded to Paris. In order that these might be viewed of the natural size, fifty magnifying-glasses are provided for the purpose, to each of which is attached a handle. By turning this handle the visitor causes to pass in review before him about eighty different specimens of foreign plants. A natural fac-simile of the photograph is appended to each, where it has been possible to procure it. Passing the collection of fruits and vegetables, we find ourselves under the palm-trees, by the banks of a river. Following its sinuosities, they lead to a lake filled with rare and curious fish, while its banks are bordered with plants of a nature seldom seen in our northern climates. In the large lake previously mentioned are the famous carp which were brought from the ornamental water of Fontainebleau, by permission of the Empress. They are of an enormous size, and are said to be two or three hundred years old. The submarine chamber, although not strictly connected with our subject, deserves notice. It is about 60 feet in length, and the first impressions created by entering it are those of mingled astonishment, fear, and admiration. The sea is above, below, on all sides; the finny inhabitants congregate in myriads to gaze upon their unknown visitors, and sea-horses and dolphins sport and gambol above their heads. A large oyster-bed, and marine plants of every hue and shape, serve to increase the illusion. Near the marine aquarium is the building devoted to the reception of Brazilian orchids; an elegant kiosk for *bouquets à la main*; a hothouse for large forced vegetables; and a beautiful little crystal palace, where, surrounded by the fruits and flowers indigenous to their tropical climate, the humming-birds pass the livelong day, flitting from one flower to another with never-tiring wing.

Situated in the avenue parallel with l'Ecole Militaire is the conservatory appropriated to the reproduction and growth of plants, and which, of all others, claims the first attention of the horticulturist. Let those who are sceptical on the subject of rapid growth enter and observe how the flower is born, grown, and multiplied, not by a process contrary and inimical to the laws of nature, but by forcing her to proceed at full gallop, by compelling her to accomplish her results in the shortest possible space of time. It is not too much to assert that the present is a forcing age, no matter in what light it may be viewed. Men never forced their brains to so injurious an extent as they do now. The minimum speed of the race of life has changed from the post-horse to the locomotive, and a man lives now in twenty years more than his great-grandfather did in fifty. It is especially a fast age—fast for the mind, fast for the body. We not only force ourselves, but everybody and everything connected us. We force all our mechanical means to the utmost, we strain the steel and stretch the iron until they can bear it no longer, and lamentable catastrophes bear witness to the truth. Discovery and invention were never so rife as now, and man's intellectual faculties are ever on the rack to keep pace with the strides of scientific investigation and research. To take relaxation and repose is to be idle, to lose time; and thus the only chance for a man to attain to the "three score and ten years" is destroyed by the restless system of life of the present century.—*Farmer.*

HINTS ON THE CULTURE OF TRICOLORED PELARGONIUMS.

It may appear somewhat presumptuous for one who has had little more than three years' experience on the subject to give that limited knowledge to the world, but my apology is that, having been frequently solicited by ardent admirers of this interesting class of plants, and feeling desirous of helping on that cultivation and wide diffusion which their great beauty justly entitles them to, I have been induced to pen this article, in the belief that it may prove serviceable to some who are but beginning to collect and cultivate these illuminators of the garden and conservatory.

A retrospective glance of twenty years or less brings to mind but few instances of variegation of the Geranium, the white or silver-edged leaf being by far the more numerous, *Golden Chain* and *Variegated Nosegay* being the only yellow or golden-edged varieties generally known. From these (more particularly the former) most of the Tricolors first introduced were obtained; but about the same period there were raised some eight or ten other yellow variegated sorts, most of which are less conspicuous, and were brought out before *Mrs. Pollock* and *Sunset*; these two sorts may, therefore, be considered the first step in advance of real Tricolors of the golden-edged class.

At the same time, several decided improvements were being effected among the silver-edged varieties, *Burning Bush* leading the way (raised by Mr. Baskett); the *Italia Unita* is now considered the best of those yet distributed.

Without doubt, much of the progress of this interesting development of brilliant-coloured leaves is due to the skill and perseverance of the esteemed raiser of *Mrs. Pollock*, *Sunset*, and *Italia Unita* (Mr. P. Grove), to whom belongs the chief place of honour of leading the van in this work of beauty.

The writer of this article desires to point out the best method of cultivating these plants in the garden and greenhouse.

In commencing the former part first, it may be supposed that the middle of May having arrived, and a sufficient stock of plants secured for the purpose of planting in beds on the lawn, here two or three preliminary matters should be referred to: First, The Drainage of the Beds. If the surface soil lies on gravel, or any open substratum which permits the passage of water freely, it is well; if, on the contrary, the subsoil is clay, or of any other retentive material, it should be taken out, and nine inches of coarse brick rubbish or broken pottery put in, placing immediately over it some fresh turf from a meadow, the grass under; over this, fill in the upper soil, which should be a light sandy fibrous loam, to which add a good dressing of decayed leaves or well-rotted stable manure; if on clay land, the bed may be raised two or three inches, as a further security against wet and, consequently, cold, which is very prejudicial to the well-doing of the plants. Avoid sunk beds, they are so many small reservoirs for surface water in rainy weather; the soil then becomes saturated, the roots diseased, and that spotting of the foliage and rottenness of the young points occur; this effect is more certain if the atmosphere becomes cold for any length of time after heavy rain.

Many growers use a portion of peat soil in the compost for growing these plants; this has no other influence than lightening the soil—leaf-mould, rotten manure, and cocco-nut fibre refuse answer the purpose much better. Our experience is against the use of peat, on account of a greater portion of plants grown partially in it becoming much more

diseased than a corresponding number grown in soil such as recommended above. Where the natural soil is deficient of sand, a portion of river or any other clean free sand may be added.

Choose the situation for beds lying as much to the south as possible, and also protected from strong cutting winds, which have a tendency to turn the edges of the leaves brown.

Various plans have been adopted in order to show up the colours of the leaves when bedded out in masses—the neutral tints of the Centaureas have been used by planting them as edgings round the beds, and in mixing them among the plants. One of the best effects yet seen was when *Tobelia speciosa* was planted plant for plant among the tricolors, the blue forming a very effective and pleasing ground colour, on which the gold and crimson leaves of the tricolors shone out brilliantly in the summer sun. Many other experiments will be made during the season for this purpose: at present our experience is but limited.

The history of bedding out silver Tricolors has yet to be written. At present none of those distributed approach in excellence the golden-leaved varieties; there are several now in existence well adapted for this purpose—time alone will enable us to determine which are the best.

Having enjoyed the beauty of these plants during the summer season, and September drawing near, the utilitarian thought arises of securing the increase. If the season is damp, the cuttings should be taken off not later than the second week of the month; if the situation is warm and airy, the operation may be deferred for a week or two longer, but there is danger from frost and wet in so doing; in the earlier part of the month the cuttings are more fitted to root and get established before winter: these should be inserted in thumb-pots singly, using very sandy loam only. Place the pots on gentle bottom heat, using water very sparingly, and in three weeks they will be sufficiently rooted.

By the middle of October, at latest, the old plants should be carefully lifted, the soil shaken off the roots, which should be slightly trimmed; place them in as small pots as will conveniently contain them; put them on gentle bottom heat for a fortnight, when they may be moved to the greenhouse, on airy shelves, using water sparingly during the winter months.

GREENHOUSE OR CONSERVATORY CULTURE.

It is here, in a greater degree than in the open garden, the writer anticipates an increased amount of pleasure will be derived. Under glass the plants are unaffected by rain and storms; here the amateur may enjoy an uninterrupted survey of the wondrous changes wrought (instrumentally) by the hand of man. To the uninitiated it may seem enough to possess one or two varieties, but to the trained eye of the connoisseur the distinguishing characteristics of even one hundred varieties are plainly visible. And who can describe the huddling forth of the young foliage in spring? each variety unfolding its glorious colours in a greater or less degree, some more gorgeous at first, others attaining to their full tints at a later period of the season, deepening on even to latest autumn. The time will come when, for the proper cultivation of these gems of Flora, a whole house, properly constructed, will be devoted to them; they need this, and well deserve such convenience. Consider the enduring nature of their beauty all the year round—contemplate the vast variety of shades of colour, from white, silver, cream, to sulphur, lemon, yellow, and orange on the edges of the leaves; again, admire the rainbow hues of the zones, varying in the depth and shades of each colour from pale rose to pink, carmine, lake—even as deep as purple among the silver class; then glance at the zones of orange, deepening, in various varieties, to red, from red to rich brown and crimson in the darker, and to scarlet and vermillion in the lighter shades. How magnificent a well-grown plant of *Sun ray*, with its intense fiery crimson zone, clouded with jet black, the sight of which drew forth the simple yet natural similitude of the sun setting behind and shining through a black cloud, from the lipa of a working gardener!

There is yet another feature of these plants requiring notice. Some of the varieties produce leaves of a light hue, which intensify in colour as they advance in age; others, again, are dark in their first state and get lighter. Again, one or two varieties in our possession produce leaves both dark in zone and bright yellow on the edge of the leaf; these change gradually; the zone becomes scarlet, the edge of the leaf nearly white. Imagine these various shades on a single plant—how beautiful an object! But when a house is properly arranged, the varieties skilfully contrasted, so as to blend and harmonise their colours, however frequently you may visit them they never pall on the appetite of taste, for the simple reason that (unlike the most beautiful flower) they are ever changing: you walk through them to-day and admire; to-morrow they have changed; a development has taken place; young leaves have grown larger, colours have become deeper, paler, or brighter, and, if carefully managed (though, it must be admitted, in a diminished degree), the beautiful tints may be maintained throughout the winter. To obtain these results, let us proceed to describe the conditions necessary to their health.

The tricolor delights in light, free air, and during the winter months and all cold weather a dry atmosphere; in hot summer weather a thin shade is requisite from ten a.m. to three p.m. To describe a structure suitable for these conditions, let us propose a span-roofed house, as admitting the greatest degree of light: this should be at the angle of 45°, with a roof ventilator the whole length of the house—the width should be say twelve feet; side lights may be dispensed with, but ventilators, extending the whole length on each side, should exist. These may be near the ground, so as to admit the air under or opposite the pipes, thus warming it as it enters the house; the inside needs but a row of slate slabs, three feet six inches to four feet wide, on each side; the pipes for heating should be two rows, of four inches, on each side. It is, by far, better to have too much heating power than too little in this uncertain climate.

In regard to temperature, there is no doubt that most variegated plants are more tender than the same species green, and tricolors require from five to ten degrees more warmth than the ordinary zone. But to have them in colour in the autumn and winter requires air as well as heat; there must, therefore, be a corresponding amount of heat kept up to modify and warm the admitted outer atmosphere—fifty degrees is the minimum and sixty the maximum at which, with admitted air (without sun-heat), it is desirable to keep them—and if this can be done night and day (except in dangerous frost) the plants will grow more robust; in sunny days, of course, the heat will range higher, but if the ventilation is good, eighty degrees will not hurt the foliage or deteriorate the health of the plants.

The proper periods for shifting on these plants vary with the intention of the grower and the condition of the plants, but the first spring shift should not take place before the middle of February, and if the plants have

been kept at a lower temperature than here indicated, the operation may be deferred to the end of the month; these may be again shifted, according to their strength of head and root, into large pots for the season, about the end of April or middle of May. When autumn arrives, such as have been cut down may be disrooted and repotted in smaller pots, as before directed for out-door plants from the beds. All those plants intended for winter decoration should consist of young plants potted in July; these will not require to be shifted before February.

Watering should at all times be commensurate with their actual want at the time. Never water them so heavily as to last two or three days beyond their need; this is too frequently done by inconsiderate persons, particularly if the plant be rather dry and the day warm, whereas no one knows what a day may bring forth; many plants are ruined by this overdose of water, followed by cold cloudy weather, or an accidental lowering of the temperature of the house. If these remarks apply in summer, they have double force in winter, when very careful watering is requisite.

Manure of various kinds has been tried in liquid form, but without any apparent benefit or superiority over the plants grown in soils as before recommended, the conclusion arrived at being against its use, as detrimental to health, evidenced from a number so treated becoming sickly in winter in a much greater degree than those grown in sandy loam and decayed manure or leaves. In potting for winter, use a larger amount of drainage (say one-third), and pot rather lighter than for spring; it is a good plan to secure the main stem with a stick to steady the plant; tie out the laterals to admit light and air among the foliage, and be careful to remove all decaying flowers, leaves, and even the small leaflets; if not removed, they generate mildew or fungus, which attacks the bark, ascends to the tender centre of the shoot, and causes that punctured appearance on the foliage, frequently destroying the plant.

In conclusion, reference might be made to the new sorts now offered for the first time, but it is preferred that these should speak for themselves. About one hundred varieties will this season be kept on view, and every explanation required freely given. The structure in which they are grown will be found in some respects novel and useful for the proper cultivation of the plants, and a visit to Dulwich will well repay the cost and trouble incurred in obtaining a sight of the largest collection of Tricolors in the world.

Nursery, Park Road, Dulwich.

F. T. SMITH.

Miscellaneous.

AUSTRALIAN SPINACH.—At the commencement of last year Mr. Ramel, who introduced into the French colony of Algiers the *Eucalyptus globulus*, received from Australia a new vegetable. His friend Dr. Mueller, of Melbourne, had it sent to him as a substitute for Spinach; it is superior in every respect to that vegetable, easier of cultivation, and of an enormous and rapid growth, less subject to run to seed, and also of better flavour. He called the plant New Queensland Spinach. The New Australian Spinach is, however, a better name. It belongs to a group in which is comprised our common spinach; it answers botanically to the *Chenopodium auricomum* of Lindley, who described it in a few words in Mitchell's Journal on Tropical Australia. It grows abundantly in the east part, following the course of the River Narran, and it is again found in Queensland. The *Chenopodium auricomum* is an annual, with a long stalk rising to a metre. In its general appearance it resembles *Chenopodium hybridum*, that troublesome weed which overruns our fields, excepting in certain points, especially in the inflorescence, which differs. The stalk is erect, robust, angular, fluted, streaked with a violet kind of red. As regards the eatable qualities of the plant, we have recently gathered an abundant harvest of leaves from two or three plants growing in our garden. These leaves were put into boiling water to bleach them, and they were then cooked as an ordinary dish of spinach, with this difference in favour of the new plant, that there was no occasion to take away the threads which are so disagreeable in chicory, sorrel, and ordinary spinach. We partook of this dish with relish; the flavour, analogous to spinach, had something in it more refined, less grassy in taste. The cultivation is easy: sow the seed in April in a well-manured bed, for the plant is greedy; water it. The leaves may be gathered from the time the plant attains 50 centimètres in height. They grow up again quickly. In less than eight days afterwards another gathering may take place, and so on to the end of the year. —*Journal de la Ferme et des Maisons de Campagne.*

JAMAICA ARROWROOT.—The development of the arrowroot crop as a staple product of Jamaica, illustrates in a forcible manner the intimate relations that subsist between the arts of life and prevailing forms of government, or, in other words, between industry and politics. The Jamaica Cotton Company was formed for the purpose of restoring the fortunes of the island by the cultivation of cotton, the temptation to the experiment being the high price of cotton consequent on the American war. But scarcely had the company got fairly to work when their operations were arrested, and a considerable portion of their crop destroyed by the Jamaica riots. Fearing to proceed according to their original plans, they next tried the cultivation of arrowroot, and succeeded admirably; and through Mr. Wesley, of 81, Fleet Street, we have been favoured with samples of the produce. It is pretty well known that the cheap arrowroot commonly sold is simply a bad form of potato starch; but this genuine article is offered at an equally low price, and will, we trust, drive the spurious arrowroot out of the market. Thus there is a gain at last—to the public at least, if the Jamaica Cotton Company are not greatly enriched by the proceeding. Doubtless the business will pay them too; for the ordinary price of Bermuda arrowroot (2s. per lb.) is extravagant, considering how abundant is the production in suitable climates, and how simple the manufacture. The Jamaica arrowroot is sold in 10 lb. tins at 10s. each, and will no doubt be purchased by benevolent persons to give to their poorer neighbours, as well as by heads of families and managers of public institutions, amongst whom hitherto English arrowroot has been held in too much favour, because of its apparent cheapness. But a bad article is dear at any price.

THE CULTIVATION OF THE MULBERRY TREE.—The following information on the cultivation of the mulberry-tree in the kingdom of Siam will not be without interest. It is chiefly in Laos, or the kingdom of Lieng-Mai, a tributary to Siam, that the rearing of silkworms is carried on on some scale. The greater part of the silk produce is employed on the spot by native industry, so that very little of it comes to the Bangkok

market. The annual export of this product does not exceed 50,000 kilogrammes (50 tons). Of late years several lots of it have been shipped for Europe. The Laos silk is of an excellent quality, but the means used for spinning are very imperfect, so that this product is placed amongst the inferior qualities. The Annamese, who are established in the neighbourhood of Bangkok, rear silkworms, but in small quantities. They understand the method of their treatment better than the inhabitants of Laos and Cambodia, and their products are better able to compete with the good qualities of China and Japan; but the whole of the silk produced by them is used for domestic purposes, and none is found in commerce. The mulberry is the object of special care in Laos and Cambodia; but it equally succeeds in all the Siamese provinces, and the rearing of silkworms might be successfully carried on there, as proved by the attempts at Bangkok, which is less advantageously situated. It appears up to the present time that no epidemic disease has made its appearance either in Laos or in Cambodia. The Annamese, employed in the rearing of the silkworms from eggs from Laos, have observed, that after they have been re-produced three or four times a fresh stock should be obtained; this, however, seems to indicate a germ of disease. Should the worms a few days after hatching seem ill and not likely to succeed, the air is changed by taking them somewhere else; this often produces the desired result. If some crops are lost it is not due to the epidemic. The eggs are transformed into cocoons at the end of a month. Three or four crops of silk are usually produced yearly, during the months of May, June, July, and August. They can be reared during other months of the year, but with less success.

PEACH-TREES INJURED BY WASIL.—I am glad to see my old friend, Mr. Brady, endorsing your advice to a correspondent, not to disturb his injured peach-trees. Permit me to give the result of one of my many little mistakes made through life in experimenting. Many years ago I had the management of two very large peach-houses, one of which I resolved to force very early. The trees were large and excellent of their kind, but awfully infested with what gardeners call scaly bug. Now to get rid of this, I consulted several intelligent neighbouring gardeners, being then myself very young, and never having seen so desperate a case before. In doing so, I got as many different recipes as I had consulted parties. Among these compositions one contained common salt, and another spirits of turpentine. Whether it was that I exceeded the quantity in each of those ingredients or not, the fact was, I killed every young shoot on my trees down to the previous year's wood. The consequence was, I had no fruit that year, but the finest show of young fruit-bearing wood I ever saw, either before or since. The year following I had such a crop of fruit as surprised myself and all others who saw them in the market or elsewhere. The average price of those peaches sold in the market was 15s. per dozen. I could say much more on the danger of using strong chemicals in the cleansing of plants and trees, were it not the sciences being now so well considered and explained, both theoretically and practically, in the education of young gardeners and farmers of the present day—compared with the days of my early pupillage, supercedes such a necessity.—EDWARD CARROLL, *Glusnevin, Dublin, in "Irish Farmer's Gazette."*

TO PRESERVE APPLES.—Two years ago a farmer in the Palatinat found in the spring an apple in the most perfect state of preservation that had been lying all the winter in a heap of leaves of the maple tree in his garden. Last autumn he therefore packed his stock of apples in casks with dried leaves, and in the spring found them in the same state of preservation, and as firm and juicy as when first plucked. He has now published the result of his experience in the German papers for the benefit of the public.

EDUCATED SHEEP.—At the exhibition of fat cattle, sheep, pigs, &c., held at Stanley in the week preceding Christmas, 1866 (says the *Liverpool Mercury*), were two sheep, six months old, of an extraordinary size, and in splendid condition, reared entirely by hand, and born in the neighbourhood of Broad Green. Their food was cow's milk, oats, grass, and latterly mangolds, turnips, and hay. Their owner is a youth, who watched their growth with intense interest, and always personally superintended their treatment. They soon became greatly attached to him, and followed him like a dog for any distance. They were taught by him to jump and perform some gymnastic feats, and likewise to run well and steadily abreast in harness, in which the female by her action and graceful movements was particularly distinguished, the ram being occasionally somewhat obstinate and more difficult to manage. When the owner went to the exhibition, the female sheep, seeing him at a short distance, without any previous intimation of voice or gesture, made a sudden and desperate effort to get to him, but, as it happened, stuck fast half way in the attempt; both the sheep, however, immediately recognised him, thus displaying an amount of intelligence not ordinarily supposed to belong to these but too frequently much-abused animals. When the exhibition terminated on Friday evening, the sheep were returned to their owner, who intends to continue the course of instruction already commenced so successfully. It may be stated that no prizes were offered for specimens of this description, but the certificate of "highly commended" was freely awarded to them by the judges.

VILLAGE NATURAL HISTORY SOCIETIES.—In most places there is at least one person who takes an interest in nature's works. Very probably he is in humble circumstances; in all likelihood he is considered harmlessly insane by his compeers, or, as they would phrase it, "a button short." There are also usually two or three more who use their eyes, and know something of the habits of birds, insects, or plants. If these three or four would meet together and talk the matter over, they could arrange affairs according to their own convenience; and, all being straightforward, we may suppose them to agree in inviting as many people as they think likely to come, to attend at such a place on such a night. In villages it is always easy to hire a room for such a purpose at a trifling cost; and in them, as in towns, one or more of the parties interested will, in all probability, be able to lend a room or rooms, on one occasion at least. Where practicable, the sociability of the evening is much enhanced by having tea or coffee handed round before the real proceedings begin. The conversation which then arises serves to place at their ease those who might otherwise be prevented by shyness from taking part in the business of the evening. Indeed, our experience leads us to believe that naturalists seldom find any difficulty in conversing with one another, when once the ice is broken; and the pursuit of nature is so truly catholic that Churchman and Dissenter, Papist and Protestant, can alike join in it without any fear of treading upon one another's (mental) corns. The humanising influence of natural history is certainly not the least of its many charms; and it is pleasant to notice how the instinctive goodwill-feeling, which all true naturalists possess, enables them to avoid topics which are likely to be in any way distasteful to those with whom they are temporarily associated.—*Hardwicke's Science Gossip.*

Correspondence.

FORECASTING THE WEATHER.—A mode by which the weather could be certainly told—or, as the phrase is, forecast—would be a great boon, not alone to gardeners and farmers, but to all other persons, pleasure seekers amongst the number. I notice a remark you make as to Sir J. Herschell's opinion; in that I entirely concur, for I think there is very much sense in the old distichs and notions of world-long proverbs. For many years (six or seven) I have followed a weather guide which I have really found a guide—not *always* certain, but generally a most capital prognosticator. Why it should be so passes my art to discover. Why particular days should be indices to the weather to occur for some twenty days I have been unable to find out. To give you the result of my notes for seven years would take up too much of your valuable space. The general conclusion will be sufficient for the purpose. I met with somewhere (I think in the *London Journal*) the experience of a French general, whose name I forget, who was remarkable in having generally fine weather for his expeditions. The scene of his operations was Algeria. His good fortune as to the weather was remarked, and some friend, in conversation with him, joked as to his great intimacy with the clerk of the weather. The general, with a serious air, explained to him his mode of observation, and said he had remarked that the fourth, fifth, and sixth days of the moon were the indices to the weather to be expected for the remainder of the moon. As was the fourth and sixth days of the moon (as to wetness and dryness) so would be the following days of the moon, and this would be found a true guide eleven times out of twelve; and so of the fifth and sixth days of the moon nine times out of twelve; but if all three days were the same, then the guide was unerring. How true this might have been in Africa I cannot tell; the result of my observations leads me to believe that there is very much truth in the general's saying. I have found, as a general thing, that the days indicated foretell the weather until a few days of the end of the moon. If either the fourth or sixth days have only one shower during the time, then the remainder—say for about eighteen days—will be more or less wet (the day, of course, includes twenty-four hours), and so with the fifth and sixth days; but if it should be that the days pass without wet, however threatening, then may be expected fine weather. You have here my experience for several years past, and taking it as a guide, I have found it as a general thing one to be depended upon. There is a saying down here, and doubtless in other places, that we have two winters, the latter one lasting during the time the blackthorn is in bud and blossom, and by the people about here called blackthorn winter. I have noticed, however fine the weather may have been preceding this time, that when the time comes there is a change, and often an unpleasant one. I think of this latter case the explanation may be, that we have east and north-easterly winds about that time. This year appears to be a departure from the general rule, if it can be so called. The blackthorn is forward in bud; the weather is open and mild; what it may be when in blossom remains to be seen. Sailors have a rule which is said to be unerring—that according to the time of the new moon (*i.e.* the hour) so will the weather be wet or dry. I have a sailor friend who relies greatly upon this method, and when I see him, if it would prove at all interesting to your readers, I will get from him the exact data, and forward the same to you. S. B.

THE GARDENERS' COMPANY.—James the First was an eminent patron of gardening: he is especially distinguished in the annals of the art for having, in the third year of his reign, formed the gardeners of London, and those within a circuit of six miles round it, into a corporate body, consisting of a master, wardens, assistants, and commonalty. No one was to practise as a gardener unless approved of by this company within the above limits. They were empowered to examine all, and seize such seeds or other horticultural products as they might esteem defective; also to impose fines, and the offenders by the magistrates to be committed to prison until they were paid. This *charter*, as stated in its preamble, was granted on account of the great disappointment caused to persons having defective samples supplied to them. It was confirmed in the fourteenth year of the same reign. This manifests how widely and generally gardening was pursued, and that a disappointment in its products was esteemed by the monarch worthy of the exercise of his prerogative to prevent. An institution arose in the same reign that required no such restricted approbation. An academy was formed in Scotland for the improvement of gardening, which was in existence as late as 1724. It had professors, who delivered lectures. The same monarch appointed a royal botanist in the person of M. de Lobel. W. G.

GARDENING IN AMERICA.—In answer to a "Young Gardener," who requests information as to gardening prospects in America, I beg to state that a friend of mine, who has had great experience as a gardener in this country and in America, writes to me that gardeners are much in request in Virginia and the Carolinas. "Young Gardener" should write to Colonel Cannon or Mr. Macdonald, of Cannon's Vineyard, Portsmouth, Virginia. These gentlemen are establishing vineyards and large fruit-gardens in various parts of the States, and could employ well-qualified men as superintendents. The average wages are about 400 dollars per annum, with board.

Montrose.

P. MACDONALD.

ARABIS LUCIDA VARIEGATA.—Will you kindly inform me whether it is possible to get this for bedding purposes at any of the nurseries near London, for I have been unsuccessful up to the present time? It is very distinct from the other varieties. You would hardly credit it, but on writing to a nurseryman who advertises largely in your pages for it, he sent me two plants of variegated and four of the common Arabis. It has been used for two seasons at Kew as an edging with excellent effect, but it does not seem to have got into the hands of the trade to any extent up to the present time.

A VARIEGATED ALPINE.

[*Arabis lucida*, whether in its green or variegated state, is so distinct from every other Arabis, that for a nurseryman to supply another for it is unpardonable. Two years ago we saw a great stock of it at Mr. B. S. Williams's Nursery, Holloway; whether he has any stock of it now we do not know. Lately we have seen it at the Hale Farm Nursery, Tottenham, but cannot say if there is any quantity of it there. It thrives on the sandy soil of Kew, and that is the only great place near London where it may be said to do well. Usually it is a bad grower, and too much of an Alpine plant to do well on level ground and in heavy soil.]

* * * SUBSCRIBERS requiring back Numbers or Parts of THE GARDENER'S MAGAZINE to complete sets, are requested to order them through their bookseller, who can always procure them from the London publisher. At the same time, instructions should be given that in case some of the numbers required are out of print, as many as can be had should be sent, it being a rule with the book collectors, if they cannot obtain all the numbers wanted not to take any, saying they are "out of print."

Replies to Queries.

Plants for Borders.—Sea View.—You may plant any and every kind of herbaceous plant now; in fact, they may be planted at almost any season, especially when purchased in pots. It is difficult for us to advise people what to plant. We are always treating of good things, giving lists of good things, describing them, offering directions for their management, and so on; but to make our information applicable to particular cases is not always possible. If you really want to embellish a wide border, begin at once, and continue all the summer long to buy and plant, as opportunities offer—that is the way to do the thing well. Procure now plants of yellow Alyssum, white Arabis, a few Aubrietias, Aquilegias, Delphiniums, Geranium sanguineum, Geranium aconitifolium, Sweet William, Campanula alpina, Barbelieri, carpatia, persicifolia, trachelium, a few Convolvulus and Polygonatum, a few Pinks and Carnations, Lychnis flos cuculi, Chalcedonica and Ilaeana, Lysimachia thysiflora, half a dozen Potentillas, a collection of double Primula vulgaris, Rudbeckia grandiflora, a few of the Saxifragas, Statice, Anemone Japonica. It is not the best time in the year to plant such things, but there is a rule followed by experienced collectors and cultivators of herbaceous plants to this effect: the best time to plant or propagate is whenever you can get them. In some good nurseries, collections of herbaceous plants are kept in pots; but some things, such as Irises, for example, cannot be dealt with in that way. Consult the O'Shane's lists in the issues for May 27, 1865, and June 23, 1866. In the GARDENER'S MAGAZINE volumes for 1864 and 1865, will be found a series of papers on all known hardy herbaceous plants, arranged alphabetically, with advices on cultivation and selections of the best varieties. The fact is, we have written so much on the subject, that past issues of this work contain an absolute plethora of information.

Planting Beds.—S. W.—Better two kinds of Geraniums than mix Perilla with them. If these are small beds, Christine, with a scarlet, would look well in them, and be better adapted for the position. Wellingtonias may be planted as easily as any other trees; there is just no mystery at all about the matter. The best time to plant them is October. Next time you plant, knock all the earth from the roots, and spread them out carefully. Somewhere about a year ago we advised on the planting of Araucarias; if you can find the paragraph, you may take it as your guide next time you plant a Wellingtonia.

Books.—C. B.—"The Botanical Magazine" is issued monthly at 3s. 6d. per number; any bookseller can obtain it, but you must not expect to get it anywhere without ordering it first. The monthly with pictures you inquire about is not a good book; it is, in fact, almost defunct. As everybody reads French now, Verschaffel's "L'Illustration Horticole" is becoming a favourite in this country. You can obtain it free by post by ordering it through Mr. Silberrad, Harp Lane, Tower Street, London, E.C.

W. D.—The "Rose Book" will initiate you in the art of propagating roses. **Rellaw Maharg.**—Possibly an opportunity may occur during the summer to give attention to the enigma you propound, but just now it is impossible. It appears that many situated as you are make but a poor use of the numerous practical advices that have been given for years past in the pages of the Magazine.

Cyclamens.—S. B.—It is but the other day one of our contributors gave a paper on Cyclamens. Beyond what was therein stated, there does not appear to be much required. There is one thing certain, that Cyclamen Persicum may be grown on fast in a warm moist house, and he full of flowers within twelve months of sowing the seed, the bulbs being then two inches wide. This method of growing them was first made public in the "Garden Oracle" for 1863. By this method the bulbs are full grown within six months of the time the seeds were sown; thus they have time to rest before being pushed on again to flower.

Major H.—Your apple appears to be a seedling from the French Crab. If you have no history with it, the name for the present may be Pentlow Crab. It is evidently a good keeper, and for that reason valuable.

Dasyllirion acrotrichum.—R. H. N. B.—From your description of the treatment your plant has received, we are not at all surprised that it should appear as if half burnt and dying. Stove-heat is more than it can bear, and the fear of giving it too much water last summer operated greatly to its prejudice. The plants of this genus are very nearly hardy, and should be wintered with as little heat as possible; and during the summer they should stand in the open air exposed to all weathers, and while making their growth should have abundance of water. Begin at once to cool the plant down, and get it out with no other covering but the heavens by the beginning of June at least. Had it been wintered in a cool house, it might go out of doors now.

TRAVELLERS SEE STRANGE THINGS.—A gentleman was recounting his travels one evening after dinner to a friend, and commenced in this way: "When I was travelling in Russia, I was attacked in crossing a forest by a pack of twelve wolves, and from my post-chaise window I fired my revolver and killed the first wolf, and, strange to say, his companions stopped and devoured him, and then came on again to the fight. I shot another and my postilion killed a third, both of which were devoured; and so we went on until only one wolf remained, and I killed him as we were entering the town, and I observed that he was immensely fat. He, of course, had devoured all his companions." "Dear me," said the friend, "that's very odd." "Very odd," said the traveller, "but not nearly so odd as that which happened on the following day. I was out shooting antelopes, and fired at one as he stood on the top of a Craig, and, odd to say, the ball passed through his neck, and killed another which was standing on a Craig a quarter of a mile off." "That's very odd," said the friend, "Yes, but the odd part of the story is to come. The report of my rifle so alarmed an old bear which happened to be up in a tree, that he fell to the ground, broke his neck, and died on the spot." "Well," said the friend, "upon my soul, that's very odd." "Yes, odd," said the traveller, "but not so odd as the sequel to my story. A thunderstorm came on, and I sought refuge in a hollow tree, and, to my horror, I descended into a nest of young bears, where I had not been very long when I heard a strange tapping, the unmistakable signs of the return of the she-bear. She ascended the tree and was descending the hollow. With the rapidity of lightning I seized her by the tail and plunged my hunting knife into her haunches, upon which she started upwards, dragging me with her, and as she went down one side of the tree I escaped by the other." "Now, really, that's very odd," said the friend, "for it's the first time in my life I overheard of a bear with a tail." "Yes," replied the traveller, "and it was the only time I ever met with one, and that's very odd."

The Gardener's Magazine.

SATURDAY, APRIL 27, 1867.

BEDDING IS THE ORDER OF THE DAY, and within three weeks from the present time there will be a greater number of plants committed to the earth than in the remaining weeks of one whole year. The system has acquired popularity through the perfection it has attained in great gardens, under the hands of men skilled in colour, and required by their position to produce the grandest possible effects. The geometric garden is an ancient feature of the *hortus anglicus*, but the fashion of the embellishments now adopted is essentially modern, both in expression and material. Where there is ample space, variety of scenery, and the means can be afforded for this kind of display, it is appropriate and acceptable. The love of colour is as general as the love of music, and a display of bedding plants ordered consistently with the laws of chromatic harmony is full of delights for the artist, and admirably exemplifies the capabilities of decorative horticulture. Excesses and mistakes are common in all the pursuits of life, and in the practice of bedding excesses and mistakes are made occasionally. We have said much against the bedding system, on account of its frequent usurpation of all the means available in the embellishment of a garden, so that, instead of occupying a subordinate place in the scheme of operations, it came to be the sole object of the cultivator's thoughts; all his glass was occupied with bedding plants, all his time taken up in collecting and cultivating them, all his space was used for a display lasting three months at the utmost, and which was so gaudy while it lasted that the gloom which followed and preceded it was made the more profound by contrast. The remedy for this is a restriction of the space appropriated to bedding plants, both within doors and without, the furnishing of borders with good herbaceous plants, and especially with such as flower in the spring, and the improvement of the shrubberies by the introduction of choice trees. In other words, we require to subdue the bedding mania, but not to abolish bedding—in fact, to suggest its abolition would be to furnish a good reason for the incarceration of the suggester in a madhouse. Even in great places, where everything is done on a large scale, there is often too much time devoted to bedding, to the neglect of other departments of decorative gardening, and even to the detriment of the fruit and vegetable gardens.

One of the most prevalent mistakes is the idea that bold contrasts are chiefly to be aimed at in the colouring of the parterre, whereas the true artist will rather seek for harmonies. We trust we have done something for the improvement of the colouring, by directing attention both to good examples and to the laws which should regulate the practice of the garden colourist. The once fashionable but always vulgar repetition of scarlet, yellow, and blue, has given place to softened shadings and gentle transitions, to the use of leaves as well as flowers, to the larger adoption of half tints and secondary shades—to, in fact, the pretty general acceptance of the suggestions offered us in the painting of the rainbow. We may see now such combinations as Stella and Christine geraniums, Purple King verbenas, and Tom Thumb geranium, which the superficial lover of violent contrasts would fear to adopt, under an impression that such colours would kill each other. Nature affords us many examples of harmonies easily imitated in bedding plants, as, for example, in the several shades of orange shading to red, and red shading to purple in a sunset, and the combinations of colours in individual flowers, and in the plumage of birds. Contrasts are not only allowable but desirable; but they must all be subordinated to the general tone and complexion of a scheme of colours, not predominate throughout as if they had fallen together by chance, with no modulations to unite them. The reports on good examples of bedding that have been published in these columns during the past six years have not been published in vain; there has been a great advance made towards the development of the true principles of art, and we may reasonably expect that as the materials for bedding colours have been of late years vastly increased, so we shall see still further improvement in their appropriation.

A great and common defect of the bedding system is its flatness, and the tendency of the practitioner to act as though he were colouring a carpet rather than embellishing a garden. Combinations of colour require the relief which form alone can afford them. The eye soon wearies in travelling over mere circles and oblongs, and as for complicated designs in the arrangement of beds, they are for

the most part puerile, and fitted to please only on paper. There is wanting material to interest the mind where the display consists of colour only, and the remedy is in the introduction of plants of distinct and noble or graceful outlines. The feathery *Humea*, the tropical-looking *Aloe*, *Yucca*, *Palm*, *Arundo*, *Ricinus*—such things impart to colours a new beauty, and there is abundant opportunity, in every garden which is at all adapted for a bedding display, for the introduction of beautiful forms without the indulgence of any excess of what is called the "sub-tropical movement." It is desirable that, during our short summer, our gardens should not only be gay with colour, but should afford interest by their variety; and this cannot be accomplished without the aid of subjects other than those that are ordinarily designated "bedders." Moreover, we are anxious to promote any and every style of embellishment that will tend to render the garden interesting and beautiful at all seasons, and therefore we think it not improper to remind our readers at this season, that, amongst the many plants that may be grown in English gardens, there are thousands that are beautiful, and yet are not included in the ordinary category of "bedders."

PERENNIAL OR HERBACEOUS LOBELIAS.

Variety, they say, is charming, and that is one of the reasons why we should perform the part of revivalists, by searching after and introducing to the notice of the public plants that are in themselves beautiful, and in every way deserving to be extensively cultivated in every good garden collection, though some of them, through neglect or otherwise, are almost consigned to oblivion. Yet, if they are worthy, we must restore them to popularity if we can. The disappearance of many good things may to some extent be caused by the attractions possessed by the great number of novelties that are being annually introduced into our gardens, and which take our attention away from subjects of sterling merit that have long ceased to be novel. The genus *LOBELIA* may be reckoned among the many whose culture has been almost forgotten. It must be understood I do not confound with them the dwarf blue varieties used so extensively in bedding, such as *Lobelia erinus* and its progeny, including *Speciosa*, *Paxtonii*, and others, but I refer to the large-growing sorts which in my early days of gardening were cultivated as specimen plants for adorning the conservatory or greenhouse during the autumn months. Among these are some most brilliant flowers, and when well grown they have a very imposing effect. But before we proceed further we need say that the genus is poisonous, and bears considerable repute in medicine. I think every gardener should know which amongst his many plants are poisonous. As many young gardeners may not perhaps ever have had an opportunity of witnessing the larger varieties when in flower—as *Lobelia cardinalis*, *L. fulgens*, *L. splendens*, *L. purpurea*, and others—I will endeavour to describe their beauty. They generally commence to flower about the latter end of July; therefore they prove an excellent companion for *Lilium lancifolium*, as plants in flower at the same period. Their average height when in flower is from two to four feet, according to the encouragement given to their growth and amount of pot-room afforded them. They produce very long spikes, thickly studded with flowers, and continue to maintain their freshness and brilliancy of colour for a long period, if carefully attended to. They require plenty of moisture when in bloom—in fact, through all their stages of active growth. If, when in flower, the pots are supplied with saucers to stand in, it will benefit the plants, as then the roots will be enabled to have a continuous supply of moisture; for should they be allowed to suffer from drought when in bloom, it will tend to diminish the length of the flowering season.

It is a matter of regret that the culture of this class of plants has been somewhat neglected of late years, for their colours not only embrace scarlet and purple, but rose, blue, white, and various intermediate shades; not only are they adapted for pot culture, but they can also be used for bedding purposes. And here I may observe they make as grand and as effective a bed, where one is required to be planted with tall plants for a background, as any of the few good tall bedding plants. They are first-rate to mix with gladioli, tritomas, &c. They are specially adapted for large pleasure grounds, because their rich colours, when viewed in the distance, have a very dazzling and splendid appearance.

Being perennial plants, and belonging to the herbaceous section, of course the stocks of any particular variety can be increased

annually. As soon as they have ceased to bloom, let the flower stalks be cut down. This will impart strength to the young suckers or plants which are throwing up from the roots. The pots are then stood out of doors, not too much exposed to the scorching rays of the sun. Should frost or heavy rains continue, they are then put into the frames. You may separate them and pot them singly into small pots either in the autumn or early in the spring, according to the accommodation you have at your disposal for housing them. Of course, the sooner the plants are parted and potted after they have done flowering, the stronger and better they will be when the blooming season commences, as compared with those potted much later. When I have had plenty of plants of any particular variety, my practice has been to put three pieces or plants into a 48-size pot. By this means, with liberal shifts, extraordinary specimens may be expected. They do not require heat to grow them in, as they are almost, if not quite, hardy in some situations. Being gross feeders, they require a very rich soil after the first potting.

The following list comprises some of the very best varieties known:

Name.	Colour.	Remarks.
Cardinalis	Scarlet	Good old variety.
Carminata superba ..	Brilliant carmine	Robust habit.
Ru'ra sanguinea. . .	Fine scarlet, white eye. . .	Branching habit, good for beds.
Belle pyramidalis ..	Rosy purple	Strong growth.
King of Blues	Lavender blue	Very long flower.
Alba grandiflora	Tinted blue	Large and fine white tube.
Cercs	Pale rose	Very pretty.
Purple standard	Reddish purple	Good.

JOHN F. M'ELROY.

[It is with great pleasure we find Mr. M'Elroy calling attention to these beautiful plants, the princes of the herbaceous border. Last year we had an opportunity of inspecting a set of new varieties sent out by Mr. Bull, of King's Road, Chelsea, and we wish to add to Mr. M'Elroy's paper, without making him responsible, that the following twelve of Mr. Bull's seedlings are far in advance of the best average kinds in cultivation, and well deserving the attention of such of our readers as are desirous of possessing first-rate herbaceous plants: *Annihilator*, deep rose, shaded with warm violet, novel and good; *Distinction*, rose cerise, with beautiful pink shade, distinct, a pleasing variety; *Excellent*, a very fine variety, bright magenta colour, with white eye and broad lobes; *Garland*, rosy purple, flowers large and well formed, very attractive; *Glitter*, bright glowing scarlet, huge flowers, upwards of two inches across, each lobe measuring an inch and a half long; *Matchless*, rich purple, with bright rose suffused through each petal; *Mulberry*, flowers of large size, with fine compact habit, colour a deep mulberry; *Nonsuch*, upper petals violet rose, margined with vermilion, under petals intensely bright, very showy; *Peach-Blossom*, one of the most attractive kinds ever offered, beautiful peach colour, with fine broadly-shaped stout petals; *Progress*, bright violet magenta, blossoms of good substance, large and fine; *Ruby*, one of the most beautiful of all herbaceous Lobelias, quite new in colour, being a very rich ruby, one of the best varieties ever sent out; *Theodosia*, bright carmine, flowers of gigantic size, a superb variety.—*ED. G. M.*]

TAGETES SIGNATA PUMILA AS A BEDDING PLANT.

So many inquiries have been made as to the adaptability of this plant for bedding, and as a substitute for Calceolarias, that I have thought it desirable to give it a special notice, this being the most speedy and convenient course to adopt to meet the wishes of those who have made inquiries respecting it. In the first place, I may say that I think our correspondents ought to have a little more compassion than to ask us to tell them if *Tagetes signata* is an annual, when, if they had only taken the trouble of consulting any ordinary seed catalogue, they would have found it was, and thus saved themselves the trouble of asking, and us the time of answering their question.

But as to the adaptability of this *Tagetes* for a bedding plant, there cannot be but one opinion by those who have seen it under favourable circumstances, for it is less trouble to raise than calceolarias, and when once it begins to flower—which, if raised early, is about the beginning of July—it continues to produce one continual mass of flower until the frost cuts it down in autumn. I remember seeing it early in the season of last year at the seat of the Earl of Clarendon, and at several adjacent places, in fine condition; and I also saw it at more than one of those places late in the summer, with myriads of its pale yellow flowers, when the calceolarias were bereft of every bloom. But, to be candid with my readers, as it is my invariable custom, I cannot say that I like the *Tagetes* as a substitute for calceolarias, for this reason only: it looks poor, or, in other words, to my mind it has not sufficient character about it to make it a fit companion for other bedding plants, more especially in the first part of the season; but, as a question of utility, it is a most deserving subject, and when looked

upon from the distance its adaptability for the parterre cannot be disputed. It is quite true that even here it may be out of place, when used largely by those who are not masters of the art of balancing colours, and I could point to an instance where such was the case last year; yet the mistake was made by one who is well known in the horticultural world as a perfect master of the art; but it so happened the party was dealing with a subject he had never properly proved for the position it occupied. The consequence was, as soon as there was a little lack of colour in other plants which surrounded it, to tone it down, there was a preponderance of yellow belts, which grated upon the eye—if I may use such a harsh expression—and from which there was no relief, on account of the predominant yellow tint; so that those who have not previously used it in the parterre or other handsomely designed flower gardens, should proceed with caution for the first time, or a failure the first season may perhaps be the means of disgusting them with what is really a good thing, in the hands of those who know its character and how to use it.

Having used, and seen it in use, for several years past, I can say in full confidence that the only plan to secure a good strain is to save your own seed from year to year, as the majority of the seed we get from the seed-shops is gathered in a haphazard manner, and is sure to produce amongst the plants some of such a straggling habit as will be sure to disfigure a bed. A bed of this plant, to look well, should be even in its growth, compact in habit, and of a uniform height; and, to secure these desirable ends, the seeds only of such plants as combine in them all these useful qualities should be saved. The plants should be raised under glass early in April, potted off either singly or two or three in a pot, gently started again in heat, and then be gradually hardened off. They like a light rich soil, and no coddling after they are once started in the new soil of the pots. It is, strictly speaking, a half-hardy annual, but, like many other bedding plants, it will endure more cold and rough usage at the end of the summer than it will at the commencement. I may remark, too, that at the time of planting out it is very impatient of a hot sun, therefore it should be shaded until its roots have got hold of the soil. In the mixed border, or in the front of shrubberies, it is a useful plant; so it is when grown in pots, but it is not many that are called upon to do such things for in-door decoration; but, for whatever purpose it is used, it will be found useful if only liberally cultivated, as it will endure both rain and drought better than anything I know in the same way of colour.

J. C. CLARKE.

THE TRITOMAS FOR MASSING AND LINES.

Those who have seen the magnificent beds of this delightful flower at Battersea Park, must confess that for massing in beds they are the most gorgeous subjects that can be used where subjects of any height are admissible. I must confess I looked with astonishment when I saw, for the first time, the striking effect they made, towering up, as they do at Battersea, to a height of some six or eight feet, and carrying such luxuriant foliage that showed up to the best advantage the brilliancy of the colours of the flowers. I have many times since regretted not seeing them growing in numbers, for, however pleasing and effective single specimens may be, they can bear no comparison to those that have numbers to assist in making an effect. Then there is another very effective way of using them, and that is to plant them in lines. Can any of your readers imagine anything more striking than a long line of these for the back row of a ribbon border, and for which they are eminently adapted, as they flower at a time when the ordinary bedding plants are in their best attire? consequently they increase the effect to a degree that can never be thoroughly appreciated until it is seen. Let me urge upon those who are extensively engaged in bedding-out plants to give them a trial, and I feel sure they will not be disappointed in the result, if the plants are liberally cultivated. But, as single specimens, they are not to be despised when grown in some conspicuous spots; for as their large heads of scarlet and yellow flowers tower up above their graceful foliage, they are sure to be admired by every lover of a garden.

Now is a good time to make fresh plantations. Secure strong plants that have not been too much mutilated by dividing, choose an open well-drained spot, and make the soil rich and deep. It should consist of leaf-soil, loam, and rotten dung equal parts. Or, if it is not convenient to prepare a mixture for them, dig in plenty of good manure before planting. Having prepared the stations, plant them at once, and place the crown of the plants just under the surface, but not more than an inch below it. The effect of this slightly deep planting I have found to considerably increase the number of suckers or offsets, and the more of these that can be secured the more effective will the plants be, if not in the first, at least in succeeding years. That they should be grown in a rich fertile spot is self-evident, from the mass of foliage, and the length and substance of the flower-stems the plant has to support. In April of last year I planted out two clumps of them, which were specially prepared by liberal manuring. From one plant I got seven spikes of flowers, and from another nine, in the early part of

the autumn of last year. The principal cause of the weak and unsatisfactory samples we sometimes see, is the absence of two essential elements—food and water. Now, in the first place, they are, as above stated, luxuriant-growing subjects, and unless they are liberally supplied with a rich soil they cannot arrive at that state of perfection that they do when their requirements are studied. Then an absence of water in sufficient quantity during the active season of growth, will do much to check that vigorous healthy development which is so essential to a high state of cultivation. When the plants are well established in a rich soil, they will not need water unless the weather is very dry; but, as soon as the first flower-spike is visible, they should have a good deluge at least every other day; never mind if it has rained the day previous, they will bear it, and continue this supply as long as a fresh flower-spike shows itself. If after following these instructions the cultivator does not succeed, I shall be tempted to say there is a spell against him, for what I have said includes all that need be said to enable any one to grow this magnificent plant to perfection.

THE MAN WITH THE BLUE APRON.

THE THUNBERGIA.

I am very fond of the species of this genus, for amongst them there are some very useful and at the same time beautiful plants. The Thunbergia has its drawbacks, like other plants, most undoubtedly, and one of them, and a very important one indeed, is this, that enemy of the garden, and most detestable pest, the red spider, is so terribly partial to it; and, as a word of advice and warning, I may as well say here, that unless "war to the knife," or more correctly speaking the syringe, is proclaimed immediately the plants are a few inches above ground, and carried on with relentless severity, the destruction of the beauty of the plants will most assuredly be effected. Against this drawback I have a capital "set off." The varieties of the Thunbergia are somewhat, if not entirely, distinct from other things in flower in the conservatory towards August; and unless one has a goodly collection of *Liliums*, and other plants of that class, there is a decided difficulty in keeping up a good show of flowers in the conservatory with plants really distinct from those grown out of doors at that season, a practice which cannot be too strictly guarded against—as much, at all events, as ever it possibly can be; for what may please out of doors in the flower-bed during the summer looks too common grown indoors through a like period; and besides, people want to see something different in their conservatory to what is grown probably by their neighbours out of doors—a very right and proper feeling too, for it gives such a common and uninteresting appearance to a place to have out and in doors both alike. Now for a word of advice respecting the management of these plants. They are readily propagated both by seed and cuttings. The best and easiest way of raising varieties of *T. alata* is by seed, and I like to sow the seed this month in some light sandy soil, and plunge the seed-pots in a strong hotbed to get the seed up quickly. As soon as the young plants are strong enough to be handled, they should be potted off into the sized pots they are to flower in, which saves a vast deal of trouble—four or five plants in a pot—and the trellis to which they are to be trained should be put to them immediately, for they are quick-growing plants, and soon entwine themselves into an inextricable mass, clinging to everything within reach. A very pretty way to train them is to stick in a few branches of wood cut like a miniature pea-stick, and let them run over that in the young state. Grow in a warm and moist atmosphere, and pot in leaf-mould and loam, and also supply the roots liberally with water. *Alata* (yellow), *alata alba* (white), and *aurantiaca* (orange), are good and suitable for this kind of treatment. As soon as they begin to flower, the plants should be removed to the conservatory and shaded carefully. There are others which are best increased by cuttings, and treated as stove plants. *Harrisii* is a magnificent species with immense flowers, measuring upwards of three inches across the corolla; colour porcelain blue shading off to white towards the mouth of the tube, which is orange yellow inside. The blooms are produced in immense racemes, most suitable for training on the walls and roof of the stove. *Laurifolia* is a rapid grower, blooming early in the spring, with beautiful blue flowers. These two last should be planted out to have them to perfection, and to enable them to be shown off to the best advantage. Soil for these should be peat, leaf-mould, and loam, with a little sand to keep it open. I have said all that is necessary, and will now ask those who derive profit from this not to forget their humble servant

BOB.

THE MAGIC RING.—Some two years a married woman at East Lulworth lost her wedding-ring in her domestic duties. A few days ago she was peeling potatoes, and on dividing a sort of double potato she found in the inside of the potato the lost wedding-ring, which she was able to identify. The potatoes were grown in a field some half a mile from the cottage, where it is supposed the ring had been carried in the manure, and the potato had grown through it.

CAMELLIA CULTURE.—No. III.

BEST KINDS OF SOILS.

On the selection of a suitable soil depends much of the success of the cultivator; therefore it is particularly essential that we should endeavour to secure, not only a suitable soil, but in such a condition as will be likely to ensure success in this particular part of the management. The essential elements of a compost are a good mellow loam, leaf-soil well decomposed, and rotten dung from a hotbed, with silver, or, what is better, either road or river sand. These ingredients, mixed in equal quantities, will grow Camellias to perfection. These substances being secured, care should be taken, previous to using them, that each is in a fit condition for use. In the first place, the loam should not be fresh from a pasture, but should have been laid by for some time exposed to the weather, and turned over at frequent intervals: the advantages of this exposure and frequent turnings consists in the fact that when so exposed it renders it sweeter, and consequently more agreeable for the roots of plants to ramify in. Besides, this exposure to the elements increases the fertility of the soil, as when all parts are equally exposed it becomes thoroughly pulverised, and the inherent crudeness of previously uncultivated soil is dissipated, and the decomposition of the vegetable matter it contains is hastened by being brought directly in contact with atmospheric agency. Consequently, as above stated, while the process of turning and exposure is going on, the fertility of the soil is constantly increasing, thus rendering it more acceptable for the purpose it is intended to serve. Such undisputed facts ought to convince every cultivator, when I urge the adoption of such precautions, that they are features in the details of camellia culture that ought to be rigorously attended to, if there is any pretensions to grow them in a skilful manner. The above remarks will apply with equal force to the other ingredients, and if each component part is thus dealt with in a systematic manner, the cultivator cannot fail to be rewarded for his pains.

Having thus far prepared them, and secured them in a tolerably dry condition, each part should be carefully broken up with a spade or some other instrument, *but not sifted*. I have placed the last sentence in italics because it is important to remember that the camellia does much the best when its roots are allowed to permeate in an open, porous, rather lumpy soil. When the ingredients are sifted, the minuteness and cohesion of their particles will be found so far impervious to atmospheric agency as to be ill adapted for the production of those fine healthy roots which vigorous camellias are noted for, and without which they soon fall into ill health.

Having endeavoured to condense into as short a space as possible the principles which should be observed by the cultivator in the selection and preparation of the soil, it only remains for me to add in connection therewith that all should be well mixed; and if any part of the collection should require shifting before or during the month of March, the soil should be warmed by being placed in a forcing house, or some other warm place, a few days before using it. When the potting occurs later in the season, if the soil is taken into a warm potting shed a week before it is wanted, it will get sufficiently warm for the purpose. These are all details that in themselves may appear trifling to the inexperienced reader, but they are all essential to success, and ought to be scrupulously wrought out by those who wish to excel their neighbours in camellia culture.

Next I may refer to the importance of using clean pots at every potting, and if new ones are used, to the importance of well soaking them in water some days before, and in every case to use them sound and dry. The crocks, too, should be clean; for dirty crocks only tend to encourage vermin, which will choke up the channels the crocks are intended to afford for the unappropriated water to get away.

Having previously cautioned the reader against the common practice of over-potting, I shall confine my remarks in this paragraph to the few details that belong to the work of

POTTING.

In the first place, I cannot too strongly impress upon inexperienced cultivators the importance of securing perfect drainage. This can only be secured by a careful packing of the crocks used for the purpose, and the placing of a bit of moss or some of the rough soil over them, to prevent the finer soil from finding its way down into the drainage, and so stop up the ordinary means of escape for the water. Next, they should be potted firmly; but never resort to the use of a rammer, as some people advise, as it renders the soil too close, and checks the spreading of the young roots so freely as they would do in a more open medium. Neither should the pots be filled to their rims with soil, but sufficient space must be left to hold enough water to gently soak the whole ball of earth through at one watering. But the cultivator must be guided in this case entirely by the size of the pot, as the larger the pot the more space must be left—say for a 10 or 12 inch pot two inches at the least. For the want of sufficient space to hold water, many large plants

suffer from drought to a degree not generally admitted, because very few will take the trouble to go round and water a plant the second time. The consequence is, that when a large plant is very dry, not more than half of the soil the pot contains is moistened; and then people wonder why their plants are infested with insects, and otherwise in an unhealthy state, when at the same time their own management is at fault. The time of shifting offers a good opportunity for the cultivator to clean his plants of all dirt and insects with which they may be infested. It is necessary, too, that this should be done if any such thing exists, as without being free from all pests of that description no plant can thrive.

INSECTS.

If there should be more dirt than can be effectually got rid of by the use of the syringe or garden engine, let each plant be carefully sponged, for the sponge is the most effectual and sometimes the most speedy method of cleansing them from all dirt. Very troublesome insects are the white and brown scale and the mealy bug. To eradicate these, the safest and surest remedy I have found is the Gishurt compound: about four ounces to a gallon of water, applied with a paint-brush. Two, or at the most three, applications of this composition, of the strength indicated, will be sure to effectually cleanse the plants of vermin.

We have now to consider where is the best position to place them after potting to induce them to make an early and vigorous growth. Undoubtedly the best is ainery, as the shade of vines that are at work is very agreeable to the camellia when making a new growth. But if ainery is not to be had, then a peach-house at work would do, or, indeed, any place where the light is not too strong, and the force of the sun's rays does not strike directly upon them, and where the temperature does not go below 60° at night, nor above 75° by day. Their chief delight is in a warm humid atmosphere, where the light is somewhat subdued, and where they can be copiously syringed night and morning. Generally speaking, from eight to ten weeks is long enough for them to remain to complete their growth in such structures, and then they may be removed to a more airy house, that they may be assisted in the formation of their flower-buds by an abundance of fresh air. Water must be given liberally during this time, and avoid the use of stimulants in the case of all newly potted plants. But the after—or, more properly speaking, the summer—treatment of these plants I must leave for my next paper.

J. C. CLARKE.

THE CALADIUM.

Crack growers of hard-wooded stuff are very apt to labour under an impression that no plant, unless it takes the greater part of a lifetime to get up a creditable specimen fit to grace an exhibition table, is worth the room it occupies. Such people are often inclined to look rather with contempt upon this genus, simply because it is easy to manage. Well, I will not dispute the point with them, for they are now met with in nearly every good collection of fine foliage plants, and I shall not be counted at all singular in sticking to my favourites. Most undoubtedly the Croton, and other hard-wooded foliage plants, are extremely beautiful, and both have their respective merits and claims upon our attention. Those kinds which retain their foliage during the whole year are lovely through the winter as well as the summer; but of course they take up space, and to preserve the plants in health they require a proper stove to keep them in; while the Caladiums we dry off, and they can be packed away in a very small corner, which is of vast importance in places where room is limited. In the spring we have nothing to do but to start them into a new growth, and we have plants fit for a king in next to no time. It is not every one who is so fortunate as to possess a stove and other houses, for particular purposes and objects. Very many who grow a considerable variety of plants have to grow the whole of their possessions in one or two houses, and these, in all probability, are already devoted to the culture of fruit. Notwithstanding the limited space contained in two or three little houses, they may be desirous of enjoying some of Nature's charms in the shape of ornamental-leaved plants. Now the Caladium is just the plant to suit them, for the bulbs can be, as I said before, stored away during the winter; they can be started in the cucumber pit or house, as the case may be, and afterwards grown in theinery, provided, of course, they are being brought along early. I wish to be understood, that I am by no means an advocate for mixing up a lot of plant-growing with the fruit department; but when it has to be done, and every inch of glass has to be taxed to the utmost of its capability, I contend that this plant is decidedly better than lots of things that I have in my time seen growing in ineries and other fruit-houses. The cultural directions could be summed up in a very few words, if I were merely giving directions or advice to those skilled in plant culture; but, as I presume this will be read by numbers who know nothing further about them than the beautiful appearance the plants present at the flower-shows, and in their neighbours' conservatories, I am naturally enough compelled to

enter into more minute particulars than would otherwise be necessary. I am in a difficulty as to what time of the year will be best for us to take for our starting-point. Suppose we begin from now, for this is the best season to begin with a new stock. Generally speaking, the young plants are by this time advanced in growth sufficiently to enable us to see the shape and colour of the foliage; and, another important consideration, there need be no fear of any risk being incurred in starting them, as there would be if purchased in the dry bulbs; while at the same time it gives us ample time to grow them to good-sized plants by the autumn. This month is the second anniversary of my taking the genus in hand, and I started in a very small way indeed. I had some little offsets given me, no thicker than the top of the penholder with which I am writing this. I had seven or eight species and varieties; I forget at this moment the exact number, and now I have more than a couple of dozen of sixteen and twenty-four sized pots as full of young shoots as they possibly can be. They have just burst into leaf, and in a few days, probably before this is in the hands of the subscribers of the Magazine, they will be shifted into No. 4's and 6's. I am not writing this with any egotistical feelings, but simply to show that it is by no means necessary to purchase large and expensive plants. They are the identical specimens which were rather highly spoken of in the report of the Kingston Flower Show last June; but through, I presume, a typographical error, a Mr. Gower had the credit for them.

On second consideration, I think we had better step back to the first of March; a week or two sooner or later is of no consequence. I fix that date as a good starting-point. The bulbs are potted in rather small pots, a bulb two or three inches in diameter in a 32-size; but, of course, when several are put in one pot the size must be in proportion, and also when the bulbs are seven or eight inches through them. For the first potting I use loam, leaf-mould, and plenty of sand. The soil should be rather moist when used, as I never give a drop of water until the young shoots have pushed an inch or so above the soil: I need scarcely say that the pots must be well drained. The pots are filled with compost, a hole is made large enough to insert the bulbs; but before doing so I put a good layer of sand, and in filling the soil round them I fill sand up the sides, to give the bulbs every opportunity to emit roots readily, and cover about half an inch of soil over them, and on the top of the soil two inches of cocoa refuse, to keep the mass from getting dust-dry. I give the refuse an occasional skiff with the syringe, to keep it slightly moist. As soon as the plants have filled the pots with roots, and are pushing through, the refuse must be removed. I give them a bottom-heat of about 75° or 80°. I consider it essential to their safety to employ bottom-heat in starting them, for there is really a very great danger of their being lost if they lay in the soil too long before they commence growth. As soon as the plants get a foot or so in height, they should be repotted immediately into the pots in which they are to remain the whole season. I believe the plants do better this way than if they were put into the larger pots at first; neither do they take so much space when they are plunged, an important matter with me. For the second shift turfy loam and rotten dung are the staple commodities. Unless the loam is lumpy and full of strong fibre, they will not grow, and nothing will induce the roots to run in it. When the loam is deficient in these respects, use half loam and the same proportion of peat, broken up into rough pieces. After this shift they can be put into the most convenient position, without the bottom heat, and as soon as the pots are full of roots; and, provided the soil is open and the drainage perfect, it will be almost impossible to over-water them. The Caladium luxuriates in a thoroughly moist atmosphere of about 70°. You can very nearly see them grow when they are properly treated. It also likes shade; but I do not consider it advisable to grow them in too dark a place; it makes them too tender and unable to stand the conservatory in the autumn. At the beginning of July mine go into the conservatory, and stop there until the beginning of October, and are kept rather dry at the roots, particularly towards the latter part of the time. The plants are not exposed to any more cutting draughts than it is impossible to avoid. As soon as they come from the conservatory, they are dried off, and the pots laid on their sides in a temperature of 55° to 60°. A lower temperature is attended with danger. They must be kept quite dry until the following spring. I examine the bulbs during the winter, if I can do so without shaking them out; and if one should be decayed, if ever so little, I cut the rotten part away and rub some perfectly dry sand on the wound, the sand drying up the moisture nicely. It is a bad plan to shake the bulbs out in the autumn and keep them in sand, for they stand a very good chance of the dry rot, which, in my opinion, is decidedly worse than the wet rot. The winter is the most critical season with the Caladium, more than all the other parts of the year put together.

A good half-dozen is embraced in this list, but there are several other really good kinds.

Argyrites, neat and compact; habit small; foliage beautiful, marked with irregular blotches of puro white.

Belleynceii is stronger growing than the preceding; white, with green veins, which give it the appearance of being covered with green network.

Bicolor picturatum, a strong grower; fine large leaves, with lovely red centre.

Brogniartii, very similar to *Bicolor*, but quite distinct; a very fine kind.

Chantinii is a noble object, and the best of the *Caladiums*. It is a strong grower; fine large leaves, beautifully marked in the centre with red, and surrounded with irregular blotches of white.

Wightii is very good; large green leaves, speckled with red and white spots, which give them a very pretty appearance.

GEORGE GORDON.

NOTES FROM THE WEST.

THE WINTER, TENDER TREES, COTTAGE GARDENS, PEACH-TREES.

When travelling the other day in the west of England, I was forcibly struck with the impartiality of the late severe winter, in its effects upon different trees and shrubs that are commonly grown in this country. Passing, by the South-Western Railway, through that famous country for rhododendron growing about Weybridge and Bagshot, where the soil is poor and sandy, I could see the effects of the severe frost had not been so much felt there as it had in places I had hitherto visited. As I had seen much devastation in other parts of the country, I thought it worth a passing remark, as the fact that many plants and trees remain untouched upon this poor soil, demonstrates most clearly the fact that, if we wish to acclimatize many of the beautiful exotic trees and shrubs that are believed to be adapted to this climate, we must be prepared, if we would have them remain uninjured from frost, to select sites for them where they will stand high and dry, and to furnish them with a soil that is not likely to create a late autumn growth.

It may not be such an easy matter to accomplish this, for two reasons: the first is that a poor, peaty, dry subsoil is not always to be had, and the second is contained in the fact that people generally are not satisfied with a close sturdy growth, especially in such tribes of plants as coniferae. If they do not make a rapid growth, and soon become trees, they are looked upon as worthless. But, to my mind, this is a mistake, and I think the experience of the past winter bears me out in the remark; for in almost every case where young trees were in a strong luxuriant condition in the autumn, they have been more or less affected by the late winter, while those occupying less favourable positions—that is to say, positions such as would conduce to a slow growth—remain untouched.

When approaching the more western counties, I certainly was disappointed in the appearance of the whole country, and traces of the intensity of the frost were on every side visible amongst occupants of gardens, while vegetation generally was extremely backward—the pasturage especially, in those counties noted for its abundance, was devoid of that rich refreshing hue so agreeable to the eye, which we are accustomed to see in the middle of April. The same remark will apply to the appearance of the wheat-crop; true, I saw in a few instances, where the land was well drained and highly cultivated, some excellent promises of a crop; but the majority of the fields were a yellow and weak appearance, and looked as if they stood much in need of a drier subsoil and a much warmer atmosphere. The wheat-plant, indeed, everywhere looks as if perishing for sunshine, while the spring corn, which at this time of year usually delights the eye on every side, is now conspicuous by its absence, as in comparison to the number of acres generally seen. The breadth of land sown appears to be very limited. Of all the sights that delighted me most, as the train hurried me still farther westward, were the allotment gardens cultivated by the poor. Having lately read with some pleasure the remarks of one of your able contributors on the subject of cottagers' exhibitions, I felt much interested when from time to time my eye alighted upon numbers of these gardens; and their clean well-ordered condition bespoke much for the industry and intelligence of the cultivators.

One thing only I regretted to make note of in reviewing these gardens, and that was the absence of good spring vegetables, such as broccoli and early cabbage; but I was assured, when making inquiries upon the subject, that it was no fault on the part of the cottagers, but was to be attributed entirely to a wet autumn, followed by a frost of unusual intensity. I said above, I was disappointed in the appearance of the country. Perhaps it was because there were but few enlivening subjects supplied by nature to greet the eye, as, being an ardent admirer of British plants, I thought to have seen more of my old favourites in their spring garb; but in this I was disappointed, as even in these reputed warmer districts there were but few showing themselves.

I must relate one other circumstance in which I was much concerned; and, to make myself understood, I must first say I had the pleasure of inspecting the gardens of Cothelston Park; but, to my surprise, I found that the cultivation of the peach and nectarine was almost a failure on the open walls—so much so, indeed, that large orchard houses had been erected to grow them under glass. To me this was a most discouraging thought; for as I began to look about me, and to get somewhat to understand the position of the place, I felt an inward desire to give expression to my opinion that, of all the positions I had ever seen as likely to be favourable for their culture, this was eminently superior to any I had yet visited. Standing, as the gardens do, on the gentle slope of a high hill, sheltered from the north by extensive plantations, and enjoying the salubrious air of one of those favoured districts of Somersetshire, one would have thought a failure in peach and nectarine culture impossible. But, unfortunately, years of careful attention have proved it to be so; and, as the most sure means of reaping any benefit from the labour bestowed, the proprietor has found it necessary to erect glass houses for them. I stated above I was interested in this subject, because I remember reading in these pages a statement by one of your coadjutors, that it was impossible for any one unacquainted with the spot to say that peaches could be successfully grown until it had actually been proved; and in the above instance we have sufficient evidence that his views are correct.

I saw also at this place a useful garden structure, which I must some day sketch out and send to you, for the benefit of the readers of the GARDENER'S MAGAZINE; but I must wait a more leisure-hour, having already extended these notes to more length than I intended.

WESTWARD HO!

EARLY PEAS.

The following is a sketch of a contrivance I have adopted with success for raising early peas in a frame, and establishing them in the open ground, so as to avoid the check which the ordinary method of transplanting from pots or boxes necessarily entails.

A A (drawn 1-6th the actual size) represents a wooden frame or box, with loose bottom B B, made of rough 1/2-inch boards, and of the following dimensions—2 1/2 inches in vertical depth, 2 inches wide at the top, 3 1/2 inches wide at the bottom, and 3 feet long, inside measurements. The bottom is simply a loose 1/2 inch board, about 4 1/2 inches wide, temporarily attached to the box by two pieces of string. The box is filled with light rich soil, and the peas sown from the narrow side.

The transferring of the ready-made row of peas to the open ground is a simple process: a drill, rather deeper than is necessary for sowing peas in the open ground, is worked out with the hoe, and the boxes, each containing a yard of peas, are placed end to end in it. The strings which attach the body of the box to the loose bottom are released, and by slightly raising it on one side the bottom board is easily slipped from under. The frame from being bevelled readily delivers itself from its contents, and the row of peas is left *en masse* in the drill without the soil being broken or disturbed, or any check being given to the peas.

These narrow seed-boxes really occupy but very little space. They can be stacked two deep (the edges of the bottoms of the upper layer resting on the top edges of the sides of the lower layer), and a cold frame of 6 feet square would contain 40 lineal yards.

For the earliest crop little more than half the seed that would be sown in the open ground is required, as the boxes are under protection till past injury from birds and slugs. I believe that the saving of seed (which, at from 1s. 6d. to 2s. 6d. a quart for first crop, is a consideration) will quite counterbalance the extra trouble of transferring to the border.

On February 19th I sowed a number of these boxes with Carter's First Crop, and at the same time made a sowing in the open ground; the latter are not yet up (this is a high and rather a late situation), but those in the boxes, after being hardened off in a sheltered place for a few days, were transferred to the open ground, earthed up and stuck on the 28th of March, at once forming two very regular and vigorous rows, which I doubt not will be a fortnight in advance of the others sown in the open ground.—Geo. Maw, F.L.S., Benthall Hall, Broseley, in "Gardener's Chronicle."

THE RADISH AS A TABLE VEGETABLE.

The late Mr. Knight very justly remarked that in spring, about May, the old turnips were gone, and the new ones not come, and he proposed forcing turnips to supply this deficiency. Here the radish steps in to supply, and from year's end to year's end the veriest clown of a gardener may have an excellent succession of radishes. I have had some cooked in the plainest manner possible, with only a little salt in the water, and they are delicious to eat, and very beautiful to look at upon the dish. To say anything to gardeners on the culture of radishes would be superfluous; but, for the sake of cottagers, let me add, that those I ate were as thick as my finger, and were only about thirty days old from the day of sowing. The potato ground will yield millions of radishes, both before the potato-tops cover the ground in spring and after the potatoes are harvested in autumn. I have long tried to get cottagers into the way of growing salad, being convinced of the comfort and importance of it in every family, not to speak of its economy; and when I see poor people with large spaces of ground in their gardens lying idle in summer for two or three months, I cannot help thinking that their poverty is a good deal to be attributed to their own fault: if "ignorance of the law excuses no man," surely the ignorance of culture is equally inexcusable in those who pay rent for the use of land for a certain number of growing days, and then give a number of the best of these days to the growth of weeds. If, therefore, thirty days of growing weather can be got, good cultivation will secure a crop of radishes in that time; but as I do not like to leave things vaguely, I will just weigh the crop, and measure the land, and thus count the cost of this crop and its capabilities.

"It is but a small root," the lazy man will say. True, friend; but its top is small too, and it will stand the closer on the ground, and its time is but short in coming to perfection, as compared with other crops. Three crops of radishes may be raised in the time necessary to grow one crop of potatoes; perhaps six in the time of one crop of corn. "Six crops for one year's rent!" Ay, friend, and here lies the rub; and every bit, both top and tail, of the radish is good pig food when boiled, for both have been eaten raw by Christians. The average weight of each radish is one ounce and a half, and about half an ounce of this is top or leaves, thus leaving one ounce of root; and the average of the space occupied by each plant is sixteen square inches, or nine plants in a square foot. Now this gives five pounds of roots per square yard, one hundred and fifty pounds to the perch, or about five tons fourteen cwt. per acre of roots; and if we add two tons seventeen cwt. of tops, we have eight and a half tons per acre in thirty days, and even four crops a year of this weight gives twenty-two tons of roots and eleven tons of tops per acre.

Perhaps the only way to bring this valuable root into use among cottagers (I had almost said among gardeners and farmers, for they will all have it), is to give it a fair trial, on a small scale, after potatoes, and forgetting that it is a radish, count it as a small carrot.

A. F.

SARRACENIAS.

There would be enough excuse for the collecting and nurturing of the North-American Pitcher Plants for their curiosity of structure were they not possessed of beauty. But of beauty they are so notable, that every lover of plants should procure a few examples of this most interesting family, and treat them well as I shall describe in this paper. Let me not attempt to convey to persons who know nothing of plants any idea of the structure and peculiarities of these plants. Rather I would advise all who are curious on the subject to visit some garden where they are grown at this season; and the sooner the better, as many of them have now fresh and exquisitely pencilled pitchers, and also richly painted and curiously formed flowers. In truth, they are now in perfection; but the flowers do not last long, and consequently those who only see them at the exhibitions do not see all the points that make them interesting. Leaving the physiological structure, and the botanical affinities, to be studied from the books where all these things are elaborated better than is possible in periodicals, I will direct attention to a few particulars essential to a superficial understanding of the source of the interest we take in these plants, and as properly introductory to what I have to say on the growing of them.

It will be observed, then, that the leaves of the Sarracenia are hollow cylinders, which terminate on one side in a trumpet kind of lip, like a vessel out of which fluid is to be poured, and on the other in a leafy appendage or lid. In the fully developed leaf we may notice that the principal beauty of the colouring is in this lid, which is sometimes of a dull purplish red, sometimes snow-white pencilled with carmine lines, and sometimes a delicate greenish yellow. The leaf in its whole length is strengthened by an angular stem, which is very curiously produced; and when this is cut through, it is seen to be exogenous, or an outside grower, a most surprising circumstance, botanically speaking, because, from what we are accustomed to in the forms of the vegetable kingdom, we should, until the fact were demonstrated, say that for certain these were endogenous or inside growers. It will be observed that the young pitchers have the lid fitting down quite close; but as the pitchers increase in size, the lid gradually rises, and then

we may suppose it possible that water can find its way into the pitcher, by means of condensed dew or the fall of rain. Not that water does find its way in; no, no. I will tell you how it gets there; it is secreted by the plant. If you will dissect a pitcher, you will find that the epidermis, both within and without the pitcher, is pierced with stomatoes, and the cellular tissue beneath is of a spongy texture, the cells large and destitute of spiral vessels. Inside the pitcher are numerous hairs, which project downward; and it is found that when an insect enters its downward course is easy, but escape is almost impossible; hence, we not only find water, but also flies, wood-lice, and even beetles. Ah! the way to ruin is smooth, and sometimes pleasant, and to go down is easier than to go up; so perhaps the flies find it in the pitchers, as we do also in the conduct of our life. Well, about the water and the insects. I have seen water in the pitchers long before the lid was opened to catch it. I have seen many pitchers full grown with not a drop in them; and I have seen some pitchers full that never were exposed to rain, and that were not filled by the syringing of the plants by the cultivator. I was puzzled by these phenomena, and I took some plants and kept one half of them plunged in pans

of water, and the other half I kept as dry as I could so as not to kill them. Now what was the result? Why, the plants that stood in water had full pitchers, and the plants kept dryer than they should be had empty ones. I concluded therefrom that the plant has the power of storing up surplus water against the day of want, and that what we find is usually secreted, though that they should be filled by rain is of course possible. How could it be otherwise if rain happened to fall when the pitchers were open? As to the flies, I consider they are attracted by the moisture, and perhaps a little sweetness. Put a jar of water in a house where there are crickets, and it will contain plenty of drowned crickets next morning. What, then, is the wonder that flies, finding the pitchers open, and smelling the moisture, should be tempted to their destruction? I once read, but forget how or where, of an English naturalist who considered the ichneumon fly would drag other flies and hurl them over the edge of the pitcher to destruction, as a human murderer might throw a victim over a bridge. I do not say ichneumon flies are not found in the pitchers. It is my rule to speak by knowledge, not by guess; but I think it was very illogical of the English naturalist, who mixed up the ichneumon and the flies as cause and effect in this case. There is no

mystery about the flies being there. I have seen them go down; but what use they are I do not know. My belief is, they are of no use at all to the plant; but we are not required to explain everything in nature.

As to the flower of the Sarracenia, it resembles a *Quersattel* (side saddle), and is not only curious but beautiful. Look at the picture of *S. variegata*, and you see five large petal-like segments, and behind them five sepal-like segments of smaller size; and within these organs is a sort of button. When further examined, it will be seen that the button is a kind of shield in five divisions, all else is understandable; but this particular mystery is solved when I say that the five-parted shield is the stigma, spreading over like petals, and concealing the stamens. If you look at the back of the flower, you will see three bracts, which is a slight violation of the arithmetical arrangement which prevails in the structure of plants. These flowers do not last long in full beauty; but while they do last they are beautiful objects.

SARRACENIA VARIOLARIS.

I was much pleased, at your great International Exhibition, to see two fine collections of these Pitcher Plants. One collection was representative of the skill—I will say the great skill—of Mr. Baines, gardener to H. L. Nicholls, Esq., of Bowdon, Cheshire; the other was from Mr. B. S. Williams, of the Victoria Nursery, Holloway, near London, in whose nursery I have seen many species in admirable keeping; and I am glad that amateurs who wish to grow these plants may be sure of obtaining them from this spirited collector of things noble and curious. It is the more pleasure to name these two collections because they are properly grown, and it is not often we see the Sarracenia except it is nearly dead with the worst of treatment; for the cultivators will insist that they are difficult to manage, whereas they are only the more injured the more you do for them. They are natives of the North-American continent—some of them (*S. purpurea*, most certainly) range as far north as Canada; but for the most part they inhabit the warmer parts of the temperate zone, and are always found in bogs. Thus we have a key to their culture in their habitat, and such a key is always a true one; for Nature sorts her plants into their suitable zones and climates, and we have but to take

notice of the way she places them. It is certain that Nature does not stew these plants in such a steam as the hottest of the orchids thrive in; yet many of our amateurs think there can be no place hot enough for them, and the consequence is the plants have no beauty, and, instead of spreading fast and forming great tufts, they dwindle away and are pronounced difficult plants to cultivate. The soil generally used is peat, and as a rule this cannot be surpassed, though I have grown the beautiful *S. variolaris* in pure sphagnum, in the coolest and ariest part of the stove; and I have also found an admixture of soft stone with the peat or sphagnum useful. The orchid grower will understand their requirements when I say that the soil which suits a *Cattleya* will suit a *Sarracenia*.

But this is not all. They want a certain degree of warmth with air, but must never be exposed to wind, more especially a drying wind, nor, as before remarked, to a great heat. "Water, water, everywhere," seems to be the song they sing. They must have water, and they must have light. Shading is most injurious, and quite destroys the beauty of the pitchers. I always place them on a shelf of an intermediate house or greenhouse, very near to the glass, and every one stands in a pan of water. *Purpurea* does not need so much heat as even an intermediate house, and it may be grown as well in a frame as a greenhouse. As to the standing in water, neither Mr. Williams nor Mr. Baines follow this plan; but they place their plants in the fullest light and comparatively cool, and keep them always wet by means of the syringe. I can testify that this treatment answers, for I have lately seen Mr. Williams's stock, and the fine colouring of the pitchers, and the plenty of flowers borne on stout stems, are proofs that the pan of water is not a vital question. Still I say to my practical friends, follow nature—she knows best—and you will do better than the best you have done hitherto; for, remember, perfection in plant growing is a comparative, not an absolute matter. When I think on these things, the songs of my country recur to my mind; for here is a plant that in its love of sun and air and water is like the eagle, the swallow, and the swan; and of such has Schlegel sung, as I would be fain to sing again in the English, though it is but poor after the German.

THE SWAN.

My tranquil life is passed the waves among,
Light ripples tracing as I glide along;
And the scarce-ruffled tide, as in a glass,
Reflects my form, unaltered, as I pass!

THE EAGLE.

In the clefts of the rock my wild dwelling I form,
I sail through the air on the wings of the storm;
'Mid dangers and combats I dart on my prey,
And trust the bold pinion that bears me away!

* * * * *

THE SWAN.

For me the heaven's blue arch hath charms serene and bland,
And odorous flowers attract me to the land;
While basking in the sun's departing beam,
I stretch my white wings o'er the purpled stream!

THE EAGLE.

I exult in the tempest, triumphant and bold,
When the oaks of the forest it rends from their hold;
I demand of the thunder—the spheres when it shakes—
If, like me, a wild joy in destruction it takes!

As the tenor of the poem will not further suit for quotation in this connexion, I proceed to say that it is very essential to keep these plants cool in winter, that they may rest naturally, as they do in their native bogs, where they are sometimes subjected to much cold,—to freezing, in fact; though such as *variolaris*, which goes farthest south, as *purpurea* goes farthest north, will not bear frost when under cultivation—at least, to speak with strict regard to truth, I never had the courage to put it to such a test—and find it needs more warmth than many others. At all times, winter and summer, a current of air should pass over these plants. I do not mean a rush of air, but something the reverse of being in a close place. A moist air is good for them at all times. All about them should be frequently made wet, to cause a plentiful dew; and as to what they stand on, let it be a solid bench, not a bed of soil or a trellis, for in either of such positions they may be subjected to excess of evaporation from the too rapid movement of the air around them. Keep in remembrance that they are bog plants; they stand in water, they are bathed in vapour, yet they have fresh air and sunshine. These conditions they need when under cultivation.

Of the species there are not many. The most lovely is *S. Drummondii*, of which there are several varieties, *alba* being perhaps the best. This is of tall growth. The pitchers are nearly a yard high. The lid is most delicately veined with carmine, on a creamy pale green or snow-white ground. The flowers are dull purplish red, handsome and peculiar. The variety of *Drummondii* called *rubra*

has a most majestic habit. The pitchers are richly veined, red and pale green; the flowers mount high above them, and are of a great size, and a most beautiful purplish red colour.

S. flava is also a tall kind, the pitchers being two and a half feet high, and the flowers a trifle taller. The latter are yellowish green, quite transparent; the pitchers also are the same colour. It is a fine species. There is a variety of this called *picta*, which is more distinctly veined than the species.

S. purpurea is very dwarf, with large pouch-like pitchers distended in the middle. The colour of the pitchers is reddish, shading to dull green. The flowers are a fine red colour. This is the easiest to obtain, and the hardiest of them all. In a sheltered position in a bog, it would live through the year in any part of England.

S. variolaris has the lid of the pitcher bent over the mouth of the tube in a manner different to all the rest. It is a beautiful variety, of large growth, and has yellow flowers. The lid of the pitcher is purplish red, spotted with white.

S. psittacina is a miniature, with small pitchers which spread horizontally, with a kind of inverted hood for a lid. The appearance of a perfect pitcher of this is that of a parrot's head reversed, as when a parrot suspends itself head downwards from its perch. The pitchers are dull red, spotted with white, and the flowers are deep sanguineous red. This is very scarce at present. As for seedlings, I do not suppose any one has reared them. I have not been curious on that subject, and they are easily increased by division.

KARL PROSPER.

EDITORIAL NOTE ON MR. PROSPER'S PAPER ON SARRACENIAS.

Our able and entertaining contributor is evidently not familiar with the latest intelligence on the subject of *Sarracenia*. A better code of cultivation than that proposed by him cannot be desired, it is perfect; but we may add a few particulars that he will gladly accept, even if they should prove tedious to some of our readers. Taking the last point first, it is a matter of some interest that seedling plants of *Sarracenia variolaris* have been grown on two occasions at Glasnevin, namely, in the autumn of 1850 and the spring of 1851. Mr. Orr sowed the seeds on the surface of rotted sphagnum, covered them with a bell-glass, and kept the pan and the soil saturated with moisture, and in about a month the plants appeared so plentifully that it was conjectured all the seed had germinated. These plants did well, and were distributed by way of exchange. Dr. Moore described them as having slender awl-shaped seed-leaves, such as left no doubt that the plant is strictly exogenous. The other matter Mr. Prosper refers to is equally interesting, and therein he is undoubtedly right. He laughs at an English naturalist for supposing the ichneumon fly could have anything to do with the insects found dead in the pitchers, and properly, though the naturalist was no less a person than the usually far-sighted Sir J. E. Smith. We have, in a search through the "Horticultural Register," lighted upon the following, from the pen of Mr. Murphy (vol. i. p. 214), which deals with the case in a summary and satisfactory manner:—

The late Sir J. C. Smith, having probably examined the plant when young, and observing that the aperture of *S. adunca (variolaris)* was so completely closed as to exclude water, gave it as his opinion that the tube must have been intended to serve some other purpose; and having stated, on the authority of one of the young men in the Liverpool Botanic Garden, that the flies are deposited in the tubular leaves by a species of sphex or ichneumon, concludes that the flies are deposited by this insect, unquestionably for the food of itself, or its progeny, probably depositing its eggs in their carcases, as others of the same tribe lay their eggs in various caterpillars, which they sometimes afterward bury in the ground. I cannot avoid observing, that this quotation betrays greater inaccuracy in the late venerated president of the Linnæan Society, than one would have supposed compatible with the known industry of that close observer, and ardent lover of nature. We are not acquainted with any species of sphex or ichneumon which, in its perfect state, feeds on dead flies; and to place the fly in which the ichneumon had deposited its eggs in a situation where it must at once cease to exist, would be to frustrate the end designed in laying them, and is contrary to every thing that is known of the habits of these insects; for although the caterpillars often fall victims to these parasites, it is not until the latter have lived for some time, and have reached that stage of existence when they assume one of their metamorphoses.

A leaf of the *Sarracenia flava*, now before me, and from which the sketch was taken, contains no less than thirteen flies, principally the blue-bottle fly (*Musca vomitoria*), with two or three of the common house-fly (*Musca domestica*). I have frequently observed the former of these species, after having penetrated some distance into the tube, struggling in vain to extricate itself; but no sooner had I enabled it to escape than it flew off with its wonted strength and activity. Now, supposing it possible that any species of the sphex or ichneumon, which are occasionally observed in in hothouses, should possess the strength necessary to compel the common house-fly to enter the tube contrary to its inclination, it is far beyond the reach of probability to imagine that it could oblige the blue-bottle to do so; and, however easy it may be for the ichneumon to deposit its eggs in the sluggish caterpillar, it could by no means deposit them in the body of this strong and restless insect. But, if the flies are not deposited in the tubes of this plant by these insects, what is it that induces them to enter? Possibly, as suggested in Kirby and Spence's "Introduction to Entomology," the effluvia emanating from putrid animalcule, in the lower part of the tube, may induce the flies to enter in search of a fitting receptacle on which to deposit their eggs, or they may enter in quest of food; but, whatever be their inducement, repeated observation has convinced me that their ingress is voluntary; and having descended some length, the gradual contraction of the tube, assisted by the short stiff hairs which clothe its inner surface, and which point downwards, effectually prevent their return.

Calendar.

WORK FOR WEEK COMMENCING APRIL 27.

Kitchen Garden and Frame Ground.

CABBAGE, CAULIFLOWER, &c.—Hoe between to loosen the surface and destroy weeds. The frequent use of the hoe will obviate the need of watering in dry weather. It is only where the ground is allowed to bake into an impervious crust that kitchen crops suffer by drought.

PARSLEY.—Sow on a rich border, very thin, and cover the drills with tiles or stones for about ten days; then remove the covering, and the parsley will be found peeping through. This plan hastens the germination of the seed, which is generally very slow.

KIDNEY BEANS may be sown in the open ground now; sow also a few in pots, to make good any that miss in the rows. Sow also in pots or pans sufficient seeds of scarlet-runners for a first planting, to give an early supply. They will be a fortnight earlier in fruit than those sown in the open ground next week. The old scarlet-runner is the best for general purposes: the best white is the Case Knife.

WORK OF THE SEASON.—In cutting asparagus, take only the strongest shoots. Give plenty of water and weak liquid manure. Transplant from seed-beds as fast as the young plants get at all thick, and use the hoe wherever weeds appear, so as to keep them down, before they have time to flower. Plant out capsicums and tomatoes under a hot wall, and cover with bell-glasses till rooted. Sprinkle soot over the ground, and hoe it in a few days afterwards. Sow broad beans, peas, radish, celery, onions, cabbages, cauliflower, horsecole, beet, kidney beans (main crop), lettuce, small salads, spinach, turnips, carrots, endive, and cucumbers for planting out on ridges early in June.

Flower Garden.

ANNUALS will require thinning out, and the straggling kinds will be the better for topping. There are very few who know all that may be done with annuals by giving them a rich soil, plenty of room, and occasionally pinching out the points of the leading shoots.

SPERGULA planted this season will need constant weeding and rolling. Until the turfs join together, weeds of all kinds have their own way, unless kept in check; but after it has closed and begun to form a turf, grass is the only weed that troubles it. Established lawns of spergula need frequent rolling, and that is about all the trouble necessary to keep them in perfect order. If there are many worms in the ground, water with lime-water in damp weather, when the worms are near the surface, to get rid of them, as they not only injure but absolutely destroy this plant, by throwing their casts up in the centres of the turfs.

FLOWER BEDS are supposed to be turned once or twice during winter, and to be manured if necessary in spring. Supposing them to have had such proper attention, now is the time to turn the soil once more, and break the clods, and make all tidy. But beware of making the ground over fine. When muddled into fine powder with rake and hoe, it will either exclude air and rain from the roots of the plants, or if the rain forces admission the soil will become a sort of paste. We are no advocates for raking beds to the fineness of peat-dust, and would sooner see the surface rough with clods broken to the size of one's fist than looking as if it had been run through a sieve. Plant out Lobelias, Pentstemons, Calceolarias, Verbenas, and all the hardier kinds of variegated edging plants. If very hot sun, or very cold nights, shelter with inverted pots or branches, or if trouble and expense are not thought much of for the sake of an early bloom, hoop them over with tiffany, as tulip-beds are treated.

PLANTS ADAPTED FOR ROCKERIES.—The plants that flourish on a sunny rockery with a good depth of sandy soil are many, and easily obtained. A good wide clump of perennial Iberis would delight in the situation, and look a neat green bush all the year round—white as snow about the beginning of May. The Pink, both the species and the florists' kinds, will be less ragged and longer-lived on it than on the level by far, and the colour of its leaves would contrast well with the delightful green of the mossy Saxifrage, so well developed in mid-winter, when almost every other plant is in rags or at rest. The Aubrietias run up and down the chinks, and look far better wrapping themselves round the stone than ever they do on the level. Alyssum saxatile, which is so indispensable to the spring gardener, but which usually rots off on the London clay during the winter, would form a dense imperishable bush on it, and of course the Arabis would not object to it, that being at home everywhere. Then the variegated Arabis lucida, and the still brighter and prettier Arabis procurrans variegata would look very smart on a select spot, and contrast capitally with their neighbours. What could equal the position for the more select kinds of hardy variegated plants? The purple Shamrock, purple Oxalis, variegated Cocksfoot, Festuca glauca, silvery Artemesias, dwarf Gnaphaliums, and a dozen other good things, would look well and do well on properly constructed rockwork. The Houseleeks, of which it is not difficult to get half a dozen thoroughly distinct and hardy species, would be a great help, particularly Californicum, arachnoideum, hirtum, and the common one. Sedums might be had in sufficient profusion to make a beautiful bed of themselves, so great is the variety of form and colour that exists among them, from Sieboldii on one hand to sexangulare on the other, and all hardy as stones, and some very pretty in flower; all are pretty as regards the leafage. S. Ewersii, glaucum, album, Rbodiola, Kamtschaticum (a fine orange-flowering species), and anglicum, may be named as among the most distinct and easily obtained. Many people find a difficulty in getting good things in this way, but the fine collections now accumulated and accumulating at the York and several other nurseries will furnish nearly everything that may be required by the most fastidious which may not be obtained in a local nursery. Calandrinia umhella, well grown, would make a brilliant effect. Of the Saxifragas, pyramidalis, oppositifolia, Andrewsii, crustata, Stansfieldii, and rosularis, should not be omitted. There are nearly 150 species of this genus now in cultivation in England, and all neat and pretty in habit. The following grow as free as grass on sensibly made rockwork: Silene alpestris (pure white, and very dwarf and hardy), Dianthus petraeus (rose, the best of the whole tribe for the rockery), Achillea tomentosa (bright yellow), Campanula (several dwarf species), Erica carnea, Linaria alpina, Phlox verna, frondosa, and stolonifera, Alyssum spinosum, Veronica candida and saxatilis.

PLANTS IN FLOWER GARDEN.—Saxifraga purpurascens, S. caespitosa, S. rotundifolium, S. Pennsylvanica, S. oppositifolium, S. cymbalaria, S. aizoon, S. geraniifolia, Stactea fortunei, Aquilegia alpina, A. Skinneri, A. glandulosa, Gentiana angustifolia, Nemophila paniculata, Symphitum echinatum,

S. asperillum, Thalictrum aquilegifolium, Leontodon aureum, Ranunculus ficaria, Echium violaceum, Phlox subulata, P. ovata, Tragopogon porrifolius, Lychnis diurna plena, Papaver croceum, P. orientale, Trollium Europaeus, Cerastium tomentosum, C. Biebersteinii, Ajuga genevensis, Gentiana altaica, Anthemis tomentosa, Linum sibericum, Geranium Lancastriense, Salvia chamaedrifolia, Saponaria ocyroides.

Fruit Garden and Orchard House.

FRUIT GARDEN.—The east winds that have blown so keenly all the past week have done good for old-established trees, for there is nothing like a dry east wind to set the bloom; but recently planted trees are all the worse for them; what these most want is a leaden sky and occasional light rains. Where the garden is exposed to the east, newly planted trees should be safely staked, and the ground be liberally mulched about their roots. Protection is still needful on fruit walls, but at the first change to westerly winds it may be removed. Meantime let the trees have air as much as possible. Dry borders in gardens where the soil is rather thin and hot require now a good soaking with water. Small quantities will do more harm than good, but a heavy dose will do immense good. On deep and fat loams the trees will do very well till rain comes again.

ORCHARD HOUSE.—Trees in pots will have plenty of water and plenty of air. A good breeze through the house will do them good, and it will be a help to shut up with a little sun-heat. If this house is now over crowded with all sorts of odds and ends that have been brought in through the overcrowded state of other houses, say at once farewell to the fruit crop. The crowding of fruit houses with things that have no right to a place in them is a common cause of failure. Renew the top-dressing now, and let it be good. Trees in horders must have plenty of water. Look out diligently for the little fat grubs that cause the leaves to curl. They must be caught in detail; there is no certain manner of dealing with them wholesale.

STRAWBERRIES that have been forced require to be carefully hardened off before removing them from the protection of the glass. Place them in a cold pit for a fortnight, and then plant them out, and they will do well. Those now fruiting to have plenty of air, or the fruit will lack flavour. Discontinue the use of liquid manure as the fruit advances to ripeness.

FRUITS IN SEASON.—Apples: Ashmead's Kernel, D; Brownlee's Russet, K D; Coe's Golden Drop, D; Cornish Gilliflower, D; French Crab, K D; Hamheldon Deux Ans, K D; Holbert's Victoria, D; Minier's Dumpling, K; Nonpareil, D; Norfolk Beefing, K; Northern Spy, D; Ord's Apple, D; Reineette du Canada, K D; Reineette Van Mons, D; Ribston Pippin, D; Royal Russet, K; Spring Ribston, D; Striped Beefing, K; Sturmer Pippin, D; Winter Quoining, K D.

Pears.—Bergamotte d'Hollande, Beurré Bretonnean, Beurré de Rance, Crassante de Mars, Fortunée, K; Josephine de Malines, Léon le Clerc de Lanté, K; Van de Weyer Bates.

Grapes of last year's crop are quite over now, and the only supplies are those furnished from the early vinery. The following are now in season:—Early Chasselas, Golden Hamburg, White Sweetwater, White Frontignan, Red Frontignan, Chasselas Masqué, Muscat Hamburg, Purple Constantia, Black Hamburg, Black Prince, Trentham Black, Lady Downe's Seedling. It is early yet for Muscats to be in fine condition, but Bowood Muscat, Canon Hall Muscat, and Muscat of Alexandria will be coming in soon from first-class heated vineries.

Strawberries.—The forcing-house and pit will supply Black Prince, Keen's Seedling, Wilmot's Prince Arthur, Swainstone's Seedling, Sir Charles Napier, Ingram's Prince of Wales, May Queen, British Queen. The last, if forced with skill, has its proper flavour now.

Peaches.—The early peach-houses should now supply good samples of Small Mignonne, Ahec, Acton Scott, Early Grosse Mignonne, Early York.

Nectarines.—Bowden, Hardwicke, Hunt's Tawney.

Cherries.—Adam's Crown,* Baumann's May,* Belle d'Orléans,* Black Tartarian, Bowyer's Early Heart, Early Purple Gean, Knight's Early Black, Werder's Early Black.* The best four of these for forcing marked with asterisk.

Figs.—Angélique, Brown Turkey, White Ischia, Early Violet, Mar-seilles.

Greenhouse and Conservatory.

HERBACEOUS CALCEOLARIAS coming into bloom may be put in the coolest place that can be found for them; currents of cold air, and a close stifling atmosphere are equally prejudicial to them. Green-fly will probably be found clustering at the base of the trusses, and instead of fumigating, it will be better to remove the fly with a moist camel's-hair pencil. Young plants for late bloom must now be shifted on, and, by planting them deep in their new pots, encouraged to make roots from the stem—a plan which keeps them short and healthy. This is a good time to take cuttings, as the propagating bed is not much occupied, and a little heat suffices for these plants.

AZALEAS OUT OF BLOOM must be set growing freely in a warm moist air. Give manure-water to old plants that have filled their pots with roots, and shade during midday. Any pruning needed should be done at once, to bring the plants into shape for next year. Taken at the right moment—that is, just as they are about to break into new growth—Indian Azaleas may be very hard pruned, if required to give them any desirable form. At the same time it will be well to turn them out, reduce the ball, and repot in smaller pots with peat and turfy loam as firmly as possible. Shut them up with a moderate bottom-heat, and syringe frequently; but give very little water at the root till they start away; then give plenty of water, and keep growing till the points show the formation of bloom-buds; then harden off, and in due time put them out of doors to ripen the wood.

BEDDING PLANTS to be got from under glass as fast as possible, to harden off in the open air. Never plant immediately after removing from warm pit or greenhouse; but let them have at least a week in the open air, kept rather dry, and with some protection at night in case of frost.

CALCEOLARIAS for exhibition must now have abundance of water, and be shaded during midday; as the trusses rise give manure-water twice a week. Keep the plants cool and airy, and tie in time to keep them from getting out of shape. The herbaceous kinds will be eaten up with fly unless care is taken. Fumigate at night when the plants are dry, and next morning syringe freely. We find Gilroy's self-acting fumigator a most useful instrument; it has but to be filled, and the spirit-lamp lighted, and the house shut up, and it delivers the smoke in a cool dense cloud as long as there is a particle of tobacco left.

Roses under glass are in grand condition this season. It is of no use

to expect good flowers if vermin are left to eat them up. Fumigate twice in succession, and give plenty of air. Most of the good perennials and teas are now in full bloom in unheated houses. This is a good time to plant out roses in conservatory borders, and to prepare beds for turning out plants from small pots in May.

FUCHSIAS not yet repotted must be attended to quickly. Large shifts suit these admirably. Young plants recently struck from cuttings grow fast in cocoa-nut dust for the first shift. Those advancing to bloom must be frequently looked over, to keep down vermin, and must have plenty of syringe.

FERNS in pots require either a shift or a renewal of the soil. In either case turn them out, and break away some of the old stuff from the outside of the roots, and repot either in the same or larger pots, using good turfy loam for all strong-growing kinds, and those that must have peat to have the best peat in rough lumps. Ferns are too often starved, owing to the common but erroneous notion that a poor sandy peat is sufficient for them, which is a mistake.

GREENHOUSE PLANTS IN FLOWER.—*Clostris quercifolia*, *Cianthus puniceus*, *C. carneus*, *C. Dampieri*, *Sempervivum aizoides*, *S. canariense*, *Leptodactylon Californicum*, *Diosma succulenta*, *D. subulata*, *D. rubra*, *D. corymbosa*, *Epacris grandiflora*, *E. miniata*, *Diplacis glutinosus*, *Entaria pungens*, *Gastrolobium speciosum*, *Dillwynia sericea*, *D. junipera*, *D. speciosa*, *Olea dioica*, *O. Americana*, *Euchilus obovatus*, *Berchemia floribunda*, *Gardoaquia multiflora*, *Habrothamnus elegans*, *Grevillea acuminata*, *Bignonia capreolata*, *Gompholobium angustifolium*.

FRAME PLANTS IN FLOWER.—*Deutzia scabra*, if not forced, is now in its full beauty. Double wall-flowers in pots are now at their best; *Ornithogalum thyrsoides*; various species of *Genistas*, *Cytisus*, *Coronilla*, and a few of the early-flowering *Ixias*; also *Diclytra spectabilis*, *Sempervivum arachnoideum*, *Echeveria secunda*.

ERICAS IN FLOWER.—*Andromedaeflora*, *daphneflora*, *cinerascens*, *Coventryana*, *Lawsoni*, *crassifolia*, *viridi purpurea*, *dumosa*, *erubescens*, *ferruginea*, *longiflora*, *primuloides*, *procera*, *refulgens*, *Russelliana*, *tubiflora*, *turgida*, *vestita blanda*, *ardens*, *floribunda*, *celesiana*, *baccans*, *calycina*, *capitata*, *perspicua*.

SEEDLING CYTISUS.—All these seed freely, and the seedling plants come generally true to their parents, even in the case of peculiar varieties. The amateur cultivator will find it an agreeable recreation to raise seedling stock of the choicer kinds of *Cytisus* and *Genista*, and there will always be the incentive of an expectation of something novel and valuable; for though they are so little apt to vary from the original type, there will be found many variations of habit and vigour in a batch of seedlings. The seed should be gathered before it is dead ripe, for fear of loss by the spontaneous opening of the pods, and should be sown in a mixture of peat and leaf-mould, and placed on a gentle hotbed. If early sowing is not convenient wait till the middle of May, then sow in shallow pans, cover the seed with the sixteenth of an inch of soil, lay a square of glass over each, and place them on a back shelf of a warm greenhouse or in a frame, and in three weeks there will be plenty of small plants. The seedlings from the early sowing will be potted in thumbs singly in May; the soil to be peat and leaf-mould and silver-sand, equal parts. In July they will require a shift to 60-sized pots, and the soil is then to be peat, leaf, and turfy loam, equal parts. They will require a little care as to watering from the first, because of the tendency of peat to dry quickly, and from the 1st of August or in a frame with the lights off night and day to harden them for the winter. When housed for the winter the majority will be handsome plants of from four to twelve inches in height, and some will show such a naturally bushy habit as to require no stopping or training. Seedlings raised by sun-heat in May will only need one shift, and as they will be less forward by winter time than those from seed sown in January, it will be advisable to prick them all out into shallow boxes, which will secure them from risk of drought, and lessen very much the trouble of keeping them. The next year, in April, they may be potted into 60-sized pots.

CYTISUS FROM CUTTINGS flower much earlier than those from seed, and for market growers cuttings are always to be preferred. The cuttings should be taken from the end of April till the end of May; short young side-shoots of two inches length are the best. These stripped of their lower leaves and dibbled into a pan of silver-sand, covered with a bell-glass and placed on a gentle heat of fermenting tan or hops, will be well rooted in about four weeks, and will then require to be dealt with in the manner described for seedlings. It is a waste of time to put in ripe shoots of the previous year, or indeed any hard and mature wood, for cuttings. The robust-growing kinds, such as *Cytisus Alleeana* and *Everestiana*, make handsome standards, if well managed. Select plants from the cutting pans which show extra vigour, and in potting use from the first a fifth-part of very rotten dung with the peat and loam otherwise recommended. At the first potting insert a straight stick in each pot, and train the leader to it. The leader must not be stopped, but all side-branches must be nipped in rather close, and those nearest the bottom be cut clean away, a few at a time, as the leader advances. If the side-shoots are cut away too fast the stem will be weak and slender, so a moderate amount of side-growth must be allowed for the sake of strengthening the stem, and these shoots are to be successively removed from the base of the stem upwards, as others are thrown out above them, to maintain a vigorous growth. When the stem is as high as desired—say from two to three feet—nip out the point of the leader, and form the head by carefully stopping and training as the growth advances. Seedling plants will always produce a fair proportion of vigorous growers, which may be grown to clean stems, and used as stocks to graft choicer varieties upon to form the head.

Stove and Orchid House.

ORCHIDS THAT MAY BE IN FLOWER.—*Saccolabium retsum*, *Arides odoratum* *cornutum*, *A. virens*, *A. virens grandiflorum*, *A. virens superbum*, *Coryanthes macrantha*, *Stanhoepa grandiflora*, *Brassia maculata* *major*, *B. verrucosa*, *Epidendrum cinnabarinum*, *E. Stamfordianum*, *Chysis bracteescens*, *Saccolabium ampullaceum*, *S. curvifolium*, *S. guttatum*, *S. præmorsum*, *Calanthe veratrifolia*, *Cattleya citrina* and *quadricolor*, *C. Edithiana*, *C. intermedia violacea*, *C. lobata*, *Cypripedium villosum*, *Dendrobium Delavonianum*, *D. Falconeri*, *D. longicornu majus*, *D. transparent*, *D. tortile*, *Laelia grandis*, *L. purpurata*, *L. purpurata Williamsii*, *Chysis Limminghii*.

ORCHID-HOUSE.—While we have fierce sunshine with east winds great care is requisite in regard to shading and air-giving in the orchid-house. Remove the shading as early in the afternoon as circumstances will allow, so that, in fact, there will be some amount of actual sunshine on the house

at the time of shutting up. Damping of walls, floors, and stages must be assiduously attended to, and plants growing freely must have water enough.

BEONIAS to be repotted if required. This is a good time to propagate. STOVE PLANTS recently potted to be kept on a good bottom-heat. Shift *GESNERIACS*, *Gloxinias*, *Clerodendrons*, and other fast-growing plants. Justicia out of bloom to be potted in peat, rotten dung, and loamy turf, equal parts. As fast as plants come into bloom, remove them to a cooler atmosphere. There must be no crowding in the stove now. Whatever can be propagated now will be better done than in autumn, as the young plants will have a long growing season before them to fill their pots with roots. Therefore buy in any new varieties of choice subjects which it may be desirable to propagate from.

Forcing Pit.

PINES showing fruit to have clear liquid manure given warm and weak. Syringe to be used before shutting up. After they have been shut up for an hour at 85°, give a little air before night, but cautiously for fear of a chill. As soon as the fruit shows colour, discontinue the syringing, and give very little water at the root. Succession plants to be kept liberally ventilated, to induce a robust growth, so that when they fruit they will not require stakes.

CUCUMBERS in fruit may be kept going now by linings of grass mowings. We have for many years used grass mowings, mixed with dry straw and other such waste, in trenches on either side of the beds; and though the heat is sudden, fierce, and of brief duration when grass is heaped up by itself, when mixed with dry litter it is more moderate and lasting, and one dressing will last well until the next mowing takes place to furnish a fresh supply.

MELONS to be kept regular in growth, and the vines some distance apart, to ensure a healthy leaf development. Plenty of sun and moderate water are essentials of success in the early growth; and we practise syringing early in the morning, and find it advantageous. As soon as a crop is set, soak the bed with tepid manure-water, and continue syringing until the fruit is fully formed; then discontinue it.

VINES from eyes this season should be shifted on as fast as they fill their pots with roots. They may have large shifts now, and be kept constantly syringed, to ensure a growth of strong rods. Muscats in bloom must have a liberal temperature till their berries are set. Vines with fruit beginning to colour to have plenty of air when weather permits, and especially for a short time before the sun gets on the house, so that the first vapours that rise may be carried off at once. All outside borders that are covered now are the worse for the covering. Remove it, to allow the sun to warm the roots.

ON THE HYBRIDIZATION OR CROSSING OF PLANTS.

By ISAAC ANDERSON-HENRY, Esq., F.L.S., of Woodend.

Read at a Meeting of the Edinburgh Botanical Society.

This may be truly characterized as the age of inquiry and investigation. Into every department of natural science men, well qualified for the work, have of late years come forward, most of them honestly intent on the pursuit of truth, to stick by its revelations, uninfluenced by theories of others, or the natural bias of their own minds. But few men who have proceeded far and discovered much are wholly free from yielding to the latter tendency. None have made such progress in discovery in this field of practical botany, or by better-tested experiments, perhaps, than our great countryman; and if ever man was more enticed than his fellows—I should rather say, his followers—in that field to run ahead and be drawn into speculations, he is that man. Dissent as we may, and will, from the conclusions to which his speculative generalizations lead, all of us must, with pride, acknowledge that Darwin has thrown more light into this department of natural science than was ever done before by any, or by all, who preceded him. What Newton was in the starry spaces, he has been in the fields below. And if Newton enunciated no theory to which his fellow-men refused assent, the same could not be said of some other philosophers scarcely less distinguished. We have all heard how Kepler, having made his extraordinary discoveries in the motions of heavenly bodies, since known by the laws which bear his name, which, though he could not at first establish by proof (yet their truth has since been amply confirmed), gave loose to fancy so far as to believe that the planetary bodies, even this earth on which we live, and move, and have our being, were themselves living creatures; and have we not all heard of the theory of Laplace, who even led Sir John Herschell, and after him a train of master minds, into the faith (which it was utter heterodoxy even to question) of innumerable creations going on, on every hand, in the remoter heavens, till Lord Rosse, one fine night, with his powerful telescope, resolved the nebulae in Orion, and dissolved the nebular hypothesis for ever? In fact, it seems the besetting sin of great and original minds, just by seeing farther, and discovering more than their less enlightened brethren, to run astray, and get bogged in erratic ground; and that either as a sequence of such discoveries or as a prelude to them—some starting with the truth and steadfastly adhering to it so far as facts will carry them, and theorizing for the rest; while others, to attain remote conclusions by a jump, boldly set forward in pursuit of the *elixir vite*, or that stone by which all metals might be transmuted into gold. And these last, pursuing an *ignis fatuus* from the beginning, stumbled in the end upon discoveries, which, however, have since been turned to good account.

If running into error, either at the outset or in the end, give any just title to distinction, I too might put forward a claim, securely based upon these double grounds; for were I to contrast my successes with my failures, it would be as setting off units against thousands.

I started in my experiments about or before the year 1840, and in firm reliance on the truth of the *Lamarckian doctrine*, as I subsequently wrote in an article I furnished, on Hybridization, to McIntosh's "Book of the Garden." I stated my belief that "nature in the beginning, as conjectured by Linnæus (I should have said Lamarck), was occupied by but few original types of the innumerable vegetable forms which have been transmitted to us. How these few first types have become varied and multiplied from classes to tribes, from tribes to genera, and from genera to species, and endless varieties, belongs to those mysteries of divine agency which set all inquiry at nought," &c.* Yet I could not discard the faith (natural enough) that by skilful manipulation and studying the times and seasons favourable and unfavourable to such operations, I could make nature

* "Book of the Garden," vol. ii., p. 319.

stretch a point so as to restore union, if not unity, between and among things related by consinship some fifty times removed; and by this means transmit among flowering plants all that was beautiful in colour, and elegant in habit, from any one vegetable form to any other at all akin to it. In like manner, among fruits, how easy did it appear to infuse the rich *aroma* of the strawberry into every cognate thing! When I look over my *notanda* of fifteen or twenty years back, I see veritably recorded in my experiment books such and such things to be done in this way—of which, perhaps, the simplest might be to cross certain species of the *Rubus* with the *Fragaria*, among which genera the raspberry in the former and the *haulbois* in the latter tribe looked promising. Again, having got a small trailing species I raised from Andean seeds (*Rubus glabratus*), I meant to cross it with *R. arcticus* or with *R. Chamamorus*—in short, I formed great designs of intercrossing the *Rubus* family, one with another, on a large scale, and felt certain of a successful issue. Though I failed in all of these, I never doubted my ability, and certainly it looked among the most feasible of things, to improve the hramble by crossing it with the raspberry. And although I have heard that such a union has been accomplished, I remain an unbeliever; for, among all the most intractable things I ever took in hand, I found the intercrossing of any one species of *Rubus* with another (and I have tried them in all possible ways, and under the most favourable circumstances) the most impracticable, and, as yet, I have only to record universal failure. I may, however, return to this tribe hereafter.

Some of my earliest efforts, however, were among what have been since denominated "florists' flowers," such as the calceolaria, the dahlia, the fuchsia, &c.

At that time every colour had been brought out in the dahlia save blue; and some began to speculate upon such a colour being realized, though none, so far as I was aware of, ever suggested the means of accomplishing it. This, however, seemed to me no great matter to achieve. I looked over the tribes bearing the nearest affinity to it, among its natural family, the *compositæ*, having the desired colour, and I found many flowering plants, such as *Aster*, *Agathaea*, *Kaulfussia*, &c., having various tints of blue, sufficient as I thought for my purpose. With the pollen of these upon a white dahlia a blue might, I believed, be obtained; but it was calling spirits from the vasty deep, for neither blue nor even white, not even a ripened seed ever came of it.

I need not allude here to similar efforts with similar results among other tribes; for, as an untaught experimentalist in hotany, I felt fettered by none of its laws, and became a law unto myself, believing that failure now might be success again, and so I went forward. Unvarying failure, however, damped my zeal bit by bit, and I began to see that I could not transfer a colour alien to any one genus from another genus remotely akin to it, to which such colour was common. Yet ere I leave this subject I may observe a rather unusual freak of nature, which I set down as due to an experiment of a somewhat similar kind. At the period I refer to, now upwards of twenty years ago, we had few species of fuchsia save *F. globosa* and *fulgens*. It was the rage then, as it partly is still, to bring out large blooms; so, with that object in view, as well as to infuse some intermixture of colour, I crossed, or attempted the crossing, of *F. globosa* with a yellow-flowered *Enothera*. I cannot vouch for the cross being true, for the progeny was a plant to all external appearance a fuchsia, like *F. globosa*, its female parent, having flowers of the ordinary *globosa* form and size, but with lightish green tips on the tetrapartite calyx. Now, although I could not regard this plant as a hybrid or mule, yet I could not reject the evidence of these light tips so far as to believe the *Enothera* had not influenced them. The fuchsia and *Enothera*, though so unlike, stand in no remote degree from each other in the tribe *Onagrarieæ*, a tribe, he it remembered, of but few genera.

Well, this was like the "glorious nibble" to the zealous angler, who fished all day on the faith of it. But it helped to keep me from further seeking to outrage the modesty of nature, as in my effort to change a white into a blue dahlia. Yet for that wild dream of fancy I was not wholly without warrant, or without a colourable pretext, for ere I gave into it I had, by crossing a red-flowered calceolaria on one with purely white flowers, produced a change in the purity of the untouched flowers of the latter plant, many of which, soon thereafter, became flushed with a roseate tint. I communicated the result to Dr. Neill, who, I remember, felt great interest in it, instancing something of a like nature produced by grafting operations, communicated to him by Mr. Brown, of Perth.

(To be continued.)

Replies to Queries.

Amaryllis.—R. W. Johnson.—Those that come most under the notice of gardeners are *A. belladonna*, *A. pallida*, *A. blanda*, *Brunsvigia grandiflora*, and their hybrids, all natives of the Cape, and as such the easiest divisions of the tribe to manage, being strictly seasonal in their growth. From these *Hippeastrum*, generally confounded with *Amaryllis*, stands quite apart. *Amaryllis* will go to rest when its season of rest comes, or will punish its possessor in some way or other; but *Hippeastrum* may be grown and bloomed at any season, and being thus without a very distinct law of its own, it requires care and judgment to manage it effectually. Respecting the *Belladonna* lily, we only need remark that it is as hardy as a tulip, that it loves sand, and when out of doors should, if possible, be planted under a wall in a shady but sheltered place, and left to take care of itself. The other species and their varieties are more tender, and we obtain a key to the treatment of them by calling to mind the climatal influences they are under at the Cape. They grow wild where the soil is very sandy; they bloom before the heat of the season has reached its maximum. After flowering, their foliage begins to die down, and just as their bulbs get to rest the heat rises to 100°, and the hulbs ripen in the natural hot-bed of dry sand, which burns the native *pelargoniums* to sticks. These points must be borne in mind by the cultivator, or he cannot expect to succeed; but once get a few good sorts, treat them as Nature treats them at home, and you will not only have a splendid bloom, but an abundance of offsets, which very soon take to a habit of flowering. But under pot culture sand alone will not suffice as a source of nourishment for *amaryllids*. The best mixture is turfy loam, thoroughly rotted and pulverized, one part; sharp sand, one part; leaf-mould, sweet and completely rotted, one part. If the loam is poor, add decomposed cow-dung, not more than one-sixth of the whole bulk. When rotted, put in a steady bottom-heat at once, the average to be 55°, the most effectual drainage

possible, and plenty of water. The flower scapes will rise in a fortnight, and the stately flowers will produce their colours and rich perfume in perfection. A tan-bed, or the coolest part of a tank in any sweet plunging material, will just suit them, and the best time to pot them is when they begin to start of their own accord. When the bloom is over, every possible encouragement should be given to the growth of the foliage, a warm moist atmosphere and an increased bottom-heat being most essential. As soon as the foliage shows signs of having done its work, dry them up, and increase the bottom temperature to 70° for a fortnight, and let them cool, and finally store away in the pots without disturbing them on a warm dry shelf, the pots laid on their sides. They ought to rest two months at least, and then may be left untouched till spring in a dry corner of the stove, or may be potted at once for early bloom. Where there is no stove they must have the warmest place in the greenhouse for flowering, and be roasted to rest on a top shelf, the bottoms of the pots turned towards the sun. A thorough maturation of the foliage, and a complete and dry rest, are of the first importance. Bearing these two points in mind, it will not be found difficult to flower them in frames and pits later in the season, and thus keep up a succession of these esteemed flowers.

Myrtle Hedge.—R. W. B.—A myrtle hedge must be managed in the same way as a stock of geraniums, or any other tender bedding plants. In October they should be taken up, and either planted out in a hed of loam in a cold pit, or potted separately and placed in a pit or greenhouse. This would be the only safe and certain method of keeping them for ever. To keep them for a few years more or less, they may be left in their places, and in a mild winter would not only take no harm, but look beautiful, and be doing good, for the annual lifting is not altogether beneficial to them. But there is a way of hitting a medium course. Plant out your little myrtles when two or three years old. Plant them early in May in strong loam, abundantly manured. In the month of June immediately following put in a lot of cuttings, and grow on a stock of young plants, and keep these plants in pots as a reserve, and if there comes a severe winter, and the hedge or ribbon line is cut off, you wait for spring, plant out the reserve, and again raise a fresh stock. The main reason why so many scrubby, leggy, and shrivelled myrtles are to be seen is because it is very seldom they get food enough. Order in large myrtles from a nursery, and what yellow-leaved, lanky, poverty-stricken plants you get! That must be borne with, because the trade are compelled to keep these things in as small pots as possible. But plant them out in a deep yellow loam with abundance of rotten dung worked in previously, and give them manure-water once a week from the end of May till the end of July, and what bouncing plants they soon become, the foliage dark and as glossy as if varnished, and the bare stems abundantly clothed with leafy twigs! and if they are in a hot position (as they ought to be) they will flower abundantly, and perhaps grow to the dimensions of trees, if allowed, before they are hurt to the extent of a leaf by any severities of weather. For a hot wall a few large myrtles are every whit as useful as the best of roses, pomegranates, or even magnolias, and the best way to train them is to allow of the free growth of breastwood, so that they will present bow fronts.

Begonia fuchsoides.—R. W.—It is scarcely possible to succeed to satisfaction with *Begonia fuchsoides* in a greenhouse. In an intermediate house it may do pretty well, but we will just say how we used to manage it years ago, and we certainly never saw it so fine as we used to have it. Cuttings were put in in April, and grown on liberally all the summer in the stove, and kept them moving all the next winter, and the following spring until June, when, if they had gone on well, they were in 12-sized pots, and fine pyramids six feet high, well furnished with branches from the pot upward. The first week in June they were set in a corner where they were sheltered from the sun and wind on the south and west by a nine-foot wall, and from the north and east by a thick shrubbery. Here they remained till the first week in August, when they were set in the greenhouse, with *gloxinias*, *achimenes*, *cockscombs*, and other things. In this situation they began to show flower immediately, and before the end of the month they were one mass of bloom, and so remained until the beginning or middle of October, when they were thrown away, as others were coming on for the next season. Our plants were the admiration of every one who saw them. We attributed their abundant flowering to the partial rest they obtained the two months they were out of doors, and the sudden excitement caused by being placed in a large airy greenhouse, under the grateful shade of vines, which partially covered the roof. We used to treat in the same way very successfully several members of the lovely genus *Æschynanthus*.

Plants for Baskets.—Brown.—The easiest and most effective basket plants are easily discovered. All the trailing *Tropæolums*, and especially those of the *Lobbianum* race, are suitable. *Campanula garganica* makes a beautiful blue fringe on the edge of a basket. *Pilogyne suavis* and *Mikania scandens* make elegant green wreaths four or five feet long. *Thunbergia alata* is peculiar as well as elegant. There is nothing else like it either in style or colour. Then there are the ivy-leaved geraniums, and the pretty variegated geranium called *Manglesii*, with *petunias*, *verbenas*, and *Lobelia erinus*, all suitable for baskets. After stopping *pelargoniums* at this time of year, you must expect to wait six weeks ere they will be full of bloom again. Later in the season, five weeks will be about the time.

ARTIFICIAL CULTIVATION OF TRUFFLES.—After a long and diligent study of the locality and natural conditions under which this esteemed delicacy is produced, M. Rousseau, of Carpentras, in France, has succeeded in his attempts to cultivate truffles, and has already raised a very fair crop. There is no reason why they should not be grown with equal facility in England, and it might well be worth the serious attention of some of our scientific agriculturists to devote a few acres of their land to give it a fair trial, the more so as a plantation of oak-trees is of importance, both in a national and pecuniary point of view. The truffle grows exclusively under oaks standing not too closely together, and free from underwood, and in a soil of chalk or light clay, with a southerly aspect, and on a slope. M. Rousseau had a suitable piece of very inferior waste land ploughed up as it for a vineyard, and then planted in distant rows, running north and south, with acorns gathered from oaks under which truffles were known to grow. After five years he was rewarded for his patience by obtaining a small quantity of truffles, which increased so much every year that the produce of his plantation, which was only four hectares or ten acres in extent, amounted, in the five years from 1862 to 1866 inclusive, to no less than 1300 kilogr. or 2,600 lb., equal to 260 lb. per acre for the five years, or 52 lb. per acre every year.

The Gardener's Magazine.

SATURDAY, MAY 4, 1867.

SPRING FLOWERS HAVE A FEW MORE ADMIRERS NOW than they have had for some years past. We begin to be persuaded that our advocacy of their claims, and our criticisms of their merits, have not been in vain, and that possibly we have turned the tide of fashion in favour of the many beautiful hardy plants that are adapted for the embellishment of our gardens, but which have for many years past been neglected, owing to the fanatical rage that has prevailed for plants that are tender in constitution and ephemeral in their attractions, and comparatively destitute of interest. In a certain sense, every plant has a claim upon our admiration of its structure, and some points of interest arising out of its history, physiology, uses, or distribution. But the general question is not raised when we direct attention to hardy plants as admirably adapted to gratify the tastes of amateurs who keep gardens and gardeners for purposes of recreation, the embellishment of the home, and as means of education for their children. It is not a general but a particular question that arises, whether all the resources of an establishment shall be directed to the production of a gorgeous display during the months of June, July, and August, to the exclusion of numerous beautiful and interesting subjects, or whether the best means shall be taken to secure interest and beauty for all seasons, even if the bedding display should have to be reduced in magnitude and glory. And, as a rule, the bedding display will be contracted, and hardy plants will have more attention and be better appreciated, and gardening will become less costly, more delightful, and will secure thousands of new votaries. In this cold and unusually late spring, when we see on every hand evidences that this is a fickle clime, the good old spring flowers have been as beautiful as ever, though later than their usual period of flowering. Even now the shady banks are everywhere dotted with primroses and violets, the open meads are poor in grass but rich in cowslips, and the cold has so retarded the bloom of pear, plum, and cherry, that in many cases we find these trees to be in bloom with the apple in the same garden, a rather rare sight, for the rule of the apple is to bloom the latest of all. There was a rather dull trade last autumn in bulbs, owing, doubtless, to the depression of trade and the general scarcity of money, consequent on a great financial crash and a small harvest. Yet several notable displays of spring-flowering bulbs have been made this year; we have remarked upon the charming display at the Temple, and we now have to notice a display of early tulips in Hyde Park, the bulbs for which were supplied by Messrs. G. Gibbs and Co., of Down Street, Piccadilly; and a display of the same beautiful flowers at the Wellington Road Nursery of Messrs. E. G. Henderson and Son. Our horticultural amateurs are scarcely aware of the vast variety and exquisite beauty of the hardy plants that flower at this season of the year. It is but in a few gardens they are to be met with; it is but in few gardens they are cared for and understood. But there is much inquiry about them. Trade cultivators, who a few years since cleared them out from their nurseries as weeds and rubbish that "did not pay," now wish they had been more wise, for they would have "grown into money" if they had kept them; and the demands of the time compel them to make purchases, at comparatively high prices, of things that ten years ago they considered as rubbish. It is a fickle climate, but not more fickle than the tastes of the people who endure its rough usage, and thrive under its assaults of heat and cold, and wet and dry, that have no rule and change from one to the other without warning. Yes, there are thousands of persons who are interested in gardening who can now see beauty in hardy border flowers, though a few years since they spurned such things as fit only for cottagers, and thought Mrs. Pollock geranium the most recherché object in the vegetable kingdom, and entitled to a garden "all to itself," with an acre of glass and a large staff of gardeners to keep it through the winter. The plain truth about the matter is that for some time past the cottagers have had the best of it: their great patches of white arabis, and yellow alyssum, and purple aubretia; their velvety and richly-laced polyanthuses, their double varieties of *Primula vulgaris*, and their sweet-scented stocks and wallflowers,—have made a mockery of the rich man's parterre, which is a mere desert, made ridiculous by being cut into ovals, diamonds, spirals, and zig-zags, all blank and bare when the cottager's garden is brimming with flowers and

eloquent with perfume, and every tree is a bower of sweets and a musical academy. Now and then we come across a cottage garden where the "bedding system" reigns supreme, and we pity the poor man who cannot be happy without aping those still poorer people who delude him with a bad example. But, as a rule, the simple-minded has the peculiar faculty of holding tenaciously to truths of permanent value, and so, while fashions change in big gardens, one good old fashion rules in little ones, and that is the fashion of loving beautiful objects without respect to their money value, or any momentary excitement that may be raised about them. There will not be seen this season amongst all the bedding displays anything to surpass a good tuft of the double crimson primrose, such as we have before us at the moment of writing this. We shall visit the great gardens, and report upon their splendours, but we shall see nothing more beautiful than our own double white, crimson, and yellow primroses, our own laced polyanthuses, our advancing tufts of elegant iris, our delicate saxifragas, our broad patches of snow-white iberis and gold-embossed alyssum. These and a thousand other beauties of not less merit take care of themselves, fetch all their own water, constitute themselves a mutual protection society, and are as proof against frost as *Lichen Islandicus*, which hugs the cold as its life and joy.

The display of auriculas at Regent's Park on Saturday last met with more general appreciation than has been the wont for some years past. The charming collections of these indescribable flowers presented by Mr. Turner, of Slough, in all the freshness that we associate with the idea of spring, and with almost more of the perfections that are looked for by the florist, were admired by many who have heretofore affected to despise such things as "florists' flowers," but have at last discovered that beauty is better than prejudice, and nature a better monitor than fashion. We have seen in our journeys westward some charming collections of spring flowers in old gardens and neglected nurseries. The time is at hand when the old gardens and neglected nurseries will be regarded as the Alhambras of floriculture, and we shall turn from ephemeral displays that are costly to things of permanent value and beauty that are as cheap as sunshine and fresh air, and wonder that the horticultural mind could have been so long under the influence of a delusion. These remarks are not intended to be antagonistic to the bedding system. Promenades and parterres need as much to be furnished, and richly furnished too, as do dining and drawing rooms. Where the bedding system is in keeping with its surroundings, it is one of the necessities of first-class gardening, as essential in its place as carpets and pictures are within doors. But when small gardens and contracted purses are enthralled by it, when an open space called a garden is kept destitute of beauty and interest nine months in the year that it may be absurdly gay during the remaining three, we can only say that such an abuse of the bedding system brings disgrace on the art of gardening; and all who are jealous of the honour of our art should pronounce such an abuse to be obnoxious, ridiculous, offensive, paltry, peurile, and inimical every way to the cultivation of what by sensible people is understood by the word *Taste*.

AMONGST VARIOUS INTERESTING EXAMPLES OF SPRING FLOWERS lately brought under our notice, we feel bound to remark upon two distinct strains of polyanthuses. Messrs. Dillistone and Co., of Sturmer Nurseries, have been for some time past diligently improving the race of border polyanthuses, and have some noble varieties. One of these at present before us has a truss of twelve flowers, each the size of a florin, thick and velvety in texture, and the form good. The centre of the flower is rich orange, heavily laid on and mealy in texture, the edge is blackish maroon crimson, marked at intervals with radiate bars of the centre orange or paste colour. The effect of a good plant of this strain in bloom is not only pleasing, it arrests attention, wins admiration, and compels the sceptic to acknowledge that after all there is some beauty and nobleness to be found in the hardy old English plants of the common garden border. Another example, of quite a different strain, has been received from Mr. Richard Dean, of Ealing. These are beautifully finished flowers, with smooth circular outlines, heavy body colours, clear bright thrum-eyes, and sharp brilliant lacing. It is a pleasing circumstance in reference to these, that they, when grown from seed, are remarkably uniform in character, but few of them sporting back to rough flowers, and the majority being of the true florists' type and exquisitely beautiful in the border. The cry everywhere is, "Who can supply polyanthuses and auriculas?" Well, we leave those who want such things to discover for themselves how to obtain them; but we cannot pass by the fact that Mr. Dean has shown that well-saved seed is not to be despised, and those who grow it may expect a good share of exhibition varieties; and those that are not perfect in their properties will nevertheless be full of beauty, and a delightful change out of the monotony, tameness, and same-

ness, which hitherto have been considered the acme of perfection in flower gardening.

Mrs. Pince's BLACK MUSCAT GRAPE has been described in these pages, and in the "Garden Oracle," as invaluable both in respect of its fine flavour and its late-keeping properties. We have lately seen the original vine, and the stock of young plants in the nursery of Messrs. Lucombe, Pince, and Co., Exeter, and wish to add to our former recommendations of this variety, that it is one of the most distinct late grapes we possess, and also one of the hardiest and most fruitful known. Only a few days since we took berries from a bunch which still hangs on the parent vine, and found them only slightly shrivelled, and remarkably rich and *croquant*. It may not make an end of the early forcing of Muscats, but it will certainly be of great service in lessening the cultivator's anxiety for an early crop, seeing that this grape hangs so well, and is so good that a last year's bunch is to be preferred at the present time to the best new grapes that are available for the dessert. In habit this grape is peculiar; the leaves are deeply and elegantly lobed, and their colour is a peculiar bluish shade of green, and the wood is of a purplish colour. The stock prepared for sale is considerable, and the plants are now growing freely in a quite cool temperature. We can only hope, as it is a pleasure to recommend a good thing, that Messrs. Lucombe, Pince, and Co., will find it difficult to make their supply meet the demand; at all events, we fully believe that Mrs. Pince's Black Muscat will, as soon as it has been fruited in a few private vineries, take the lead amongst all the newer kinds of table grapes—certainly it deserves to do so.

RICHARD HEADLY, Esq., of STAPLEFORD, NEAR CAMBRIDGE, invites tulip growers to inspect his valuable and interesting collection of these flowers, from the 18th to the 21st of this month, when he anticipates they will be in their prime. The 23rd is the date fixed for the Cambridge exhibition, when we expect and hope to see exhibited many of Mr. Headly's seedlings, of which he has a large number, and amongst them many of great promise.

STEPHANOTIS FLORIBUNDA is considered a rather tender plant, but we are enabled to place on record that in one instance at least it has proved as hardy as a myrtle or a camellia. When visiting the interesting nursery of Mr. Drummond, of Western Road, Bath, a short time since, we observed a Stephanotis in the stove just breaking nicely, and were informed that the plant had been left in a pit throughout the past winter, and that its capability of resisting frost was measured by a thermometer. It withstood 15° of frost without harm, and has now all the appearance of being in perfect health, though later in making its new growth than when housed with the usual amount of care.

A BRILLIANT DISPLAY OF SPRING FLOWERS may be seen at the present time in Hyde Park, on the walk which extends from the gates opposite the Wellington statue towards the Marble Arch. We propose to make some remarks upon these flowers next week. The object of this note is to suggest to our London readers that the scene of this display is well worth a visit.

ROYAL BOTANIC SOCIETY.

THIRD SPRING SHOW, APRIL 27TH.

In the midst of ungenial weather there were just a few bright hours to favour this the last Spring Show of the season. The contributions were comparatively few in number, but of the very highest order of merit, comprising subjects of great value and interest, such as at least were pleasant to the eyes of practical cultivators, whether of hotanical or floral proclivities. Mr. B. S. Williams was strong in foliage plants; Mr. Turner and Messrs. Lane came forward with pot roses and auriculas; Messrs. Paul and Son presented new roses; and there was a charming collection of polyanthes from Mr. Wiggins, of Isleworth, whom we welcome most heartily into this new field of labour, as a practical vindicator of the old florists' flowers.

STOVE AND GREENHOUSE PLANTS.—Under this head we shall notice both flowering and foliage examples. Mr. B. S. Williams made a grand group, consisting of *Azalea Perryana*, *Imantophyllum* *miniatur*, *Eriostemon pulchellum*, *Cordylina indivisa*, *Croton variegata*, *Yucca aloefolia variegata*; and another group consisting of *Agave filifera*, *Jubea spectabilis*, *Boronia pinnata*, *Todea superba*, *Vanda gigantea*, *Yucca quadricolor*, *Areca sapida*, *Azalea sinensis* (a valuable subject for contrast of colour), a fine pyramid *Mignonette*, *Oncidium leucochilum*, *Lycaste flavescens*, *Thujopsis dolabrata*, *Dasylyrium acrotichium*, *Lycaste cruenta*, *Cypripedium barbatum*, *Anthurium Scherzerianum*, *Lomaria gibbs*, *Tetratheca ericoides*. Mr. Burley, of Albert Nursery, Pembroke Place, Bayswater, presented a beautiful group of palms and flowering plants: conspicuous amongst them were examples of *Azalea Indica alba*, *Dracæna indivisa*, *Elais Guineensis*, *Lstania Bourbonica*, *Pandanus Javanicus variegata*. Mr. G. Wheeler, gardener to Sir F. H. Goldsmid, Bart., put up a beautiful group, comprising *Hedera macrostegia*, *Pandanus Javanicus variegata*, *Azalea Marie Louise*, *Alcaecia motallia*, *Cborozema cordata*, *Dicksonia antarctica*. In the miscellaneous class, Messrs. Dobson and Son presented a pretty collection of *Azaleas*, comprising *Rui Léopold*, *Baron de Vliere*, *Duko of Devonshire*, *Louise Margottin*, *Souvenir de l'Exposition*, *William Bull*, *Iveryana*, *Reine des Doubles*.

NOVELTIES.—Mr. Burley, of Bayswater, sent a showy *Amaryllis* called *Prince Teck*, also a species of *Xylophylla*, from South America. From Mr. Wilcocks, gardener to Dr. Paterson, St. John's Wood, *Bletia purpurea*, an interesting but not attractive orchid; *Caladium Duo de Nassau*, *Dendrobium Farmeri aurea*; *Dendrobium Heyneanum*, and *Dendrobium Cambridgeanum*, all of which have been described in these pages. Messrs. Ivery and Son, of Dorking, sent a new *Azalea* called *Fascination*. Mr. B. S. Williams presented a new and beautiful *Hymenophyllum*, and *Amaryllis aurantiaca*. From Mr. Bull, of Chelsea, a group of his new *Pelargonium International*, also the pretty *Bertolonia margaritacea*, from Brazil; *Chamærops melanocantha*, the new and beautiful *Adiantum Lindeni*, and *Saurauja sarapiensis*: the last named is a superb fine-tolaged stove-plant worthy to rank with *Splærogyne* and *Cyanophyllum*. From the same: *Azaleas*, *Queen of Roses* and *Reine des Pays Bas*. Not least meritorious amongst the novelties was the new bedding pinksy *Imperial Blue*, from Messrs. Downie, Laird, and Laing, Forest Hill: this is a beautiful addition to the last improving and enlarging list of hardy bedding plants, and will be a great favourite.

ROSES.—Messrs. Paul and Son made a splendid display of pot roses:

very noticeable for beauty were *Le Rhône*, *Madame Willormoz*, *Alba rosea*, *Souvenir d'Elise*, *Madame de Stella*, *Souvenir d'un Ami*, *Madame Boutin*, *Lord Raglan*, and *President*. From the same, three new roses: the varieties were *Duchesse de Caylus*, *Princess Mary of Cambridge*, and *Fisher Holmes*. Mr. Turner took a good place with a group comprising *Alpaide de Rotalier*, *Madame Willormoz*, *Lord Clyde*, *Souvenir d'un Ami*, *Charles Lawson*, *Celine Forestier*, *Victor Verdier*, *Professor Koch*, *Maréchal Vaillant*. Mr. Turner's group of three new roses consisted of *Duchesse de Caylus*, *Maréchal Niel*, admirably done, the colour pure yellow; *Mlle. Margaret Dombraïn*. Messrs. Lane and Son, of Berkhamstead, Herts, presented *Duchesse de Morny*, *Vicomte Vigier*, *Louise Darzins*, *Pierre Notting*, *Anna Alexieff*, *Madame Victor Verdier*, *Jean Goujon*, *Madame Alfred de Rougemont*, *Comtesse de Chabriland*. Messrs. Lane and Sons new roses were *Duke of Wellington*, *Marcella*, and *Dr. Andry*. Messrs. Lane and Son put up a collection of pot roses in addition to the foregoing. In the amateur class there were some admirable contributions. Mr. James, gardener to F. W. Watson, Esq., Isleworth, had a group of six, comprising *Baronne Prevost*, *Madame Charles Wood*, *Anna de Diesbach*, *Jules Margottin*, *John Hopper*, *François Lacharme*. Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, had *John Hopper*, *Gloire de Dijon*, *Anna Alexieff*, *Baronne Prevost*, *Princess Clothilde*, *Catherine Guillot*.

PANSIES.—Mr. James exhibited a beautiful stand of twenty-four cut blooms, comprising *Noir*, *Chancellor*, *Musseffel*, *Cupid*, *Novelty*, *Tennyson*, *Arab*, *Invincible*, *George Wilson*, *General Lee*, *Dux*, *Cherub*, *Rev. H. Dombraïn*, *Miss Cochrane*, *J. B. Downie*, *Harry*, *Concord*, *Masterpiece*, *Princess of Wales*, *Norma*, *Ladyburn Beauty*, *Blink Bonny*, *Jessie*, *Czar*. Mr. James also exhibited twelve pot pansies. Mr. Hooper, of Widcombe Hill, Bath, exhibited cut blooms and pot plants.

MISCELLANEOUS.—Mr. Wiggins maintained his well-established reputation as a cultivator of the *Pelargonium*, his group of six being admirably trained, well out, and of course fresh as the spring: the varieties were *Monte Christo*, *Vestal*, *Roseum*, *Beadsman*, *Pline*, and another. Mr. James presented herbaceous *Calcæolarias* in the same matchless style as heretofore: the varieties were *Charles Dickens*, *Gratitude*, *Lord Derby*, *Lavinia*, *Master Farrell Watson*, *Louise*. Collections of *Auriculas*, both of exhibition and alpine varieties, were shown by Mr. Turner, Messrs. Dobson and Son, Mr. James, Mr. Butcher, and Mr. Cox. Mr. Turner's best six were *Smith's General Bolivar*, *Dickson's Duke of Kent*, *Spalding's Metropolitan*, *Smith's Lycurgus*, *Lightbody's Fair Maid*, *Chapman's Soppia*. Mr. James presented a beautiful group of hardy ferns.

MANCHESTER NATIONAL HORTICULTURAL SHOW.

We had last year in London undoubtedly the finest exhibition that has ever taken place in this or any other country, and which we can say was crowned with great success. We are now most anxiously looking forward for one to be held in the Botanical Gardens of Manchester, in June; of course not upon so large a scale, but which nevertheless we hope will prove equally as satisfactory. In fact, we have no fear of success as regards the exhibition, for some of our finest specimens are cultivated in the north of England; and, from what I can learn, the growers there are preparing well to come out stronger than before. I have always noticed that when a thing is taken in hand by Manchester gentlemen, they carry it to perfection, and never will, if they possibly can help it, be conquered. And no doubt the plants there will be equal to those exhibited in London last year; but when we remember that some of the best collections came from Manchester, we cannot doubt the fact. It quite surprised me to see that Manchester had sent so much up, and that she had taken the laurels from the great London growers, who evidently thought no one could surpass them; but Manchester did, and great honour is due. Imagine them looking so fresh as they did after travelling for 200 miles; indeed, one would have thought they had just been taken from the hothouses. I hope the London growers will benefit by the example set them by Manchester, and endeavour to help them in their great undertaking. It is a special credit to the promoters of this exhibition, as they have not the subscribers to assist them that London had, but yet they have a large guaranteed fund to meet the expense, providing it does not answer so well as anticipated. By the list we have seen, it consists of the principal nobility and gentry of that part of the country. The schedule is liberal, and it appears to have been the aim of the committee to suit every exhibitor, as there are prizes offered for nearly every class of plants that constitute a grand display. It will be held under canvas, which is far better for showing the plants to advantage: turf banks will form the arrangement. The gardens are well calculated for a flower show; also a nice distance from the busy city. The convenience of travelling and cheap trips, we hope, will induce thousands of visitors to come. It will be the great show of the season, and all who are lovers of Nature's most beautiful productions should avail themselves of a visit.

W. B.

ACCIDENTS, EMERGENCIES, AND SUDDEN ATTACKS OF ILLNESS.—A sheet of instructions for the prompt treatment of accidents and emergencies has been issued by the Accident Insurance Company, Limited, Bank Buildings, Old Jewry, London, and published by W. H. Collingridge, of the "City Press." The instructions were prepared expressly for the Company by Mr. Alfred Snee, the Surgeon to the Bank of England, and may be regarded as the Science of Surgery in its most profound truths described in popular language, intelligible to the ordinary reader. It is very curious that no less than fifty-two distinct subjects are clearly and graphically described, and instructions are given as to what patients may safely do, and what they may not do, without medical aid; and we are informed when we may bide our time and when we should make all speed to secure the aid of a surgeon. The sheet is surrounded by thirty woodcuts of accidents, which are so beautifully drawn by Robertson and engraved by Orrin Smith, that the most inexperienced eye may in many cases immediately recognize the true character of an injury. Handy remedies, mostly in a solid form, are suggested for travellers, and no one should travel when cholera is epidemic without the solid diarrhoea tablet here described. It also tells us that one man in ten is yearly disabled, that £235,000 have been paid for compensation to persons killed and injured, and the accidents to which we are liable are clearly depicted to our minds. The sheet of instructions is so useful that it should be in every house, and probably no one will ever be found foolish enough to destroy it.

ON THE HYBRIDIZATION OR CROSSING OF PLANTS.

By ISAAC ANDERSON-HENRY, Esq., F.L.S., of Woodend.

Read at a Meeting of the Edinburgh Botanical Society.

(Continued from p. 182.)

Ere I pass from the field of my dreamland, it is right to observe that any efforts I made at that time to transmit perfume from one plant to another led to no satisfactory results, just from having no plants then near enough related to effect it. That it may be done, however, and done effectually, I have since again and again proved, as others too have proved among rhododendrons, by crossing *R. ciliatum* with *R. Edgeworthii*. I made this out long before these Sikkim species came to help us—viz., by crossing our common European alpine species, *R. ferrugineum* and *R. hirsutum*, with *R. formosum* (otherwise *R. Gibsonii*), a beautiful Indian species; and the like result I obtained by crossing the latter on *R. atrovirens*—of all which crosses I have still many plants in my garden, all quite hardy, and which flower abundantly every year. In these latter hybrids the perfume is faint compared with what it is in the *Edgeworthii* cross; but of the *Rhododendron* hereafter.

To revert to my earlier operations. Finding that nature would not do as I bid her, I resolved, as far as possible, to find out her way, and do as she bid me. I felt she had a clue to unravel, if I could only find the end of it; so I took in sail, lowered my expectations, and betook myself to merely muling.

To go no farther back with my experiments than 1842, I tried to accomplish breeds between several kinds of fuchsia and *Epilobium*, a genus certainly not far remote from the fuchsia, especially the *F. excorticata* of New Zealand. The *F. corymbiflora*, then new, I drafted into service likewise, crossing it with *E. serotina*, &c. I wrought with *E. rubra* and also with *E. alba*, to whose agency I had a notion the first pure white fuchsia (named *Venus victrix*) was in some way due. I also wrought with *Epilobium angustifolium*, and some time after this with *Zauschneria californica*, still more closely allied to the fuchsia. But I failed in all to effect an intermediate. In some cases where I inverted the cross, making the fuchsia the male parent, there appeared to be seeds partially ripe, borne by the *Epilobium*, but nothing ever came of them. I was reluctantly obliged to abandon this family altogether. One great object I had in view was to effect a change in the colour of the bloom, as well as in the habit and hardihood, of the fuchsia.

In the following year (1843) I changed my tactics. The fuchsia *Venus victrix* having a small flower, I entertained the hope, by crossing it with a fine large-flowered variety, called *F. splendida*, to produce a larger variety, with all the purity of that still the purest of all the white varieties. The better to secure this, the thought struck me of shading both the pollen and seed-bearing plants. With this view I shaded the female plant (*Venus victrix*) by covering, with thin muslin bags, its emasculated blooms, and, at maturity fertilized these with the unshaded pollen of *F. splendida*. I did get ripened seeds and sowed them, but nothing came of them—at least I obtained no purer white flowered seedlings. I inverted the cross, making *F. Venus victrix* the female and *F. fulgens* the male parent, but with no better success. I, however, got ripe seeds by this cross also.

I again, that same year, to get better expanded flowers, tried a modified form of muling, and effected crosses between *F. cordifolia* (mother) and *F. fulgens* (father), adding the pollen of the latter to that of *E. serotina*. I got ripe seeds, but of these, though sown, I have no record; and I have since been fully satisfied that in such cases foreign pollen added to native is impotent.

I hope, gentlemen, you will bear with me while I follow out some more of these operations, which, however discouraging to me hitherto, were yet, at least some of them, not wholly so disheartening as to preclude hope. There is no denying of the truth: I had pinned my faith, right or wrong, to a theory, to make the whole world (I mean the vegetable part of it) kin. I had drunk too deep of the Lamarckian spring to lose heart without further trial.

So, persevering in muling, I had got mulish in the belief in my ability in the end to surmount all, at least many, of the difficulties I had met with. But I will not tax your forbearance with the innumerable and literally fruitless experiments I made in this field, and of most of which I kept no record; so I shall pass on to some more favourable results I accomplished some few years afterwards.

I find, from my note-book for the year 1847, that I made some attempts among the *Scrophulariaceæ*, a family most of whose extant tribes stand in much closer relationship to one another than the *Onagraceæ*. The *Torenia asiatica*, a most beautiful plant, introduced about that time from India, offered to me a very tempting opportunity of forming by it a union with a Californian plant of a nearly allied genus—namely, the *Diplacus puniceus*. And I may here notice a fact I have found of almost universal occurrence among my experiments, that when I had to cross an American with an Asiatic species, it took much more kindly than crossing either of these, especially the former, with European species; and lest I shall not have another opportunity of recurring to this subject, I may here observe also the decided preference of plants of the southern hemisphere to intercross among themselves, however remote their original homes may be—e.g., I found how much easier it was to cross Australian and New-Zealand plants with their allies of South America, than with European or kindred things in the northern hemisphere. I have also observed that proper American species have greater aversion to cross with European than with Asiatic species, and that Asiatic species have no less aversion to intermix with European kinds.

There is only one instance, I remember, of effecting a successful cross between an Asiatic and a European species, and that was in crossing a small species of rhododendron with yellow *Helianthemum*-like flowers, being a form of *Rhododendron lepidotum* called *R. cleagnoides*, of the Sikkim ranges, on *R. ferrugineum*, a European kind. Of this cross I raised two plants; one died, and I kept the other for years; it flowered with me, the blooms being dirty red, splashed with a pale yellow tint. It was an odd-looking thing, and I afterwards sent it to Kew as a botanical curiosity. What became of it there I never heard.

In the early summer of 1847, I crossed the *Diplacus puniceus* with *Torenia asiatica*, and on 3rd August I got, as I believed, a pod of ripened seed, but I found I had pulled it too early, and the seeds do not appear to have sprung, at least I have no note of it if they did. I may observe here that it was and is my custom always to remove the native anthers long before maturity, deferring the cross generally for three or four days, or even a week thereafter,—in fact, till the stigma was fully matured—always marking it as so emasculated; and this was

carefully done here. From another pod of the same cross, but not so marked, I obtained nine plants, but what became of these I have no record; very likely they were failures.

I further tried, and succeeded, in crossing another *Torenia*—viz., *T. intermedia*—with the *Mimulus*, making the latter the seed-bearer. Of this cross the pod contained seventeen seeds, which I sowed on 17th September, 1847, and at October 19th I had nine plants finely vegetated. But of these I have no further record. I perhaps lost them during the following winter; for in the few proper mules I have succeeded in raising I ever found them most difficult to rear. In this cross, as well as in the following, I had, I find, made sure against self fertilization by timely removal of the male organs.

I further, in 1847, attempted a cross between the *Digitalis purpurea*, var. *alba*, and the *Torenia asiatica*, making the former the seed-bearer, and got something like immature seeds, which I sowed, but nothing came of them. In the same summer of 1847 I effected another small success by obtaining one pod of ripe seeds of *Isotoma axillaris* crossed with *Lobelia ramosa*. These I sowed on 18th September, and at 24th November I put off nine small seedlings. On September 30th I obtained of the same cross another ripened pod containing sixteen seeds, which I do not observe I had sown.

On December 4th of same year I obtained another pod of ripened seeds from the same *Isotoma axillaris*, crossed in this instance with *Lobelia coronopifolia*, from which I raised ten plants, potted off 12th January, 1848. What came of them I have no record, but I have found out, much to my cost, that of few things sown as late as October, and before January, can much account be given in the following March. Yet those who, like myself, have only been able to gather such seeds so late, are placed on the horns of a double dilemma—they must either sow at once, at great risk, or put off till spring, when, with longer keeping, the vital principle, weak at first, may be gone.

Yet the fact of seeding and raising such things at all was encouraging, and tended to make me more observant of the ways and means by which success might be made more certain. That climate, and especially some peculiarly favourable states of the atmosphere, had much to do with it, I felt every year more and more certain. I had by this time found that crosses which I could easily effect at one time were utterly impracticable at another, and that this ill-conditioned state would sometimes extend over whole summers. But of all times and seasons, I found such weather as frequently preceded thunder, and, oddly enough, which sometimes followed it—when there was a genial balmy texture in the air, not so much from sun-heat, as sometimes arises from the presence of a larger portion of electricity than is usual, when every living thing seems more than ordinarily alive and happy—to be the season of all others for a hold experiment, and I seldom failed to improve it. Such a season happened in the spring of 1850; but, before I relate a small success I then achieved, I must relate another observation which had been forced upon me from some of my manifold efforts in this way, and I think it will be better I state it by giving it as set down in my note-book, under dates April and May, 1850: "Discovered that the short stamens of *Rhododendron cinnamomeum*, and particularly of *R. Catawbiense*, crossed the small *Rhododendron* (*Rhodothamnus*) *Chamæcistus*." By the short stamens of *R. cinnamomeum* I had further crossed the same pigmy species of *Rhodothamnus* with a large white-flowered Indian species; the cross being performed in the beginning of March 1850, which I noted as then (19th May) well on towards ripening.

Off the above muling operations I got some pods of ripened seeds, especially where the *Rhodothamnus* was crossed by the large Indian rhododendron, than which none to all appearance could be more perfect—yet nature had been too far strained. I sowed the seeds, and though I preserved the seed-pot for years, not one seed ever vegetated. I was, however, more successful with another cross, which I felt impelled to try by the extraordinary mule raised by Mr. Cunningham, of Comely Bank, and about which so much mystery was observed—and for one good reason, as I have since learned, that he himself, crossing at the time so many things, one with another, did not precisely know its parentage, further than that the seed was borne by a *Menziesia* crossed, as he might believe, by the *Rhodothamnus Chamæcistus*. I have now reason to believe, from having wrought much in this section of the *Ericaceæ*, that the seeds of his mule called *Bryanthus erectus* were borne, not by the *Menziesia cærulea*, as was generally believed, but by *M. empetriformis* crossed by *Rhodothamnus Chamæcistus*; for I had myself been trying a similar cross, before I knew of Mr. Cunningham's, between *M. cærulea* and the same *Rhodothamnus*, which, however, had failed. Having thereafter, when in his nursery, been shown Mr. Cunningham's mule by himself, though he declined to say what the parentage was, I felt assured that I was not far off the truth when I told him my belief that it was the very cross I had been attempting, which he, however, would not admit. But, not to be baffled, I set to work afresh, but now inverting the cross, making *M. cærulea* the seed-bearer; for before it was the *Rhodothamnus*. It succeeded. I obtained ripened seeds in June 1850, and in September following I had four young plants, which, however, were unfortunately devoured one night by a snail. In this I had another instance of success being secured by inverting a cross.

From this time forward, I dealt liberally with the short stamens, believing, as I still do, that with these—I mean the pair of shortest stamens which occur in numerous families of plants—the larger species may be made to intermix with the smaller species of its tribe, where otherwise no union could be effected.

But here is one singular result, which I think I have fully established as resulting from the use of these short stamens, especially where the kinds crossed are homogeneous, or not remotely allied, and where there is no great disparity in size between their sexual organs.

Puruing the use of these diminutive organs, especially where I crossed a larger on a smaller species, I find that I had, in the spring of 1855, manifestly used the short stamens of *Rhododendron Edgeworthii* in effecting a cross on *R. ciliatum* (both Sikkim species), with the object of warding off the tall reed-like growth of the former, and securing the dwarfer, bushier habit of the latter species in the progeny. I gathered and sowed the seeds of this cross on 7th November, 1855, and I have still three plants alive of this brood, the height of two of them being only 4, and that of the other 4½, inches. These are now in their twelfth year, and have never shown the smallest tendency to bloom. (Two of them are now on the table before you.) I have no doubt of these being the produce of the short stamens.

Earlier in the same autumn I gathered and sowed seeds of the same

cross, effected, I have no doubt, with pollen from the longer stamens, for the plants are taller than *R. ciliatum*, and shorter than *R. Edgworthii*, the male parent, of whose delicious perfume the flowers largely partake.

My attention was first called to the like effect of dwarfishness being produced from the use of the short stamens in the pelargonium tribes by an article written by Mr. Beaton in 1861, in the *Journal of Horticulture*; and it is not unlikely that the same law holds in other races where the short stamens occur.

I was first induced to use these pigmy stamens of the larger species from the belief that their pollen must necessarily be smaller and finer in its granules than that of the larger anthers, and therefore more likely to pass down through the ducts of the female organs of the smaller kindred species. I cling to this idea still, and, if I am correct in it, may not the several pairs of anthers—i.e., the intermediate and longest styled anthers—have severally their separate functions? Much patience is needed for pursuing experiments here, but it is worth the trial. May not the colour and perfume of flowers, and the size, fecundity, and aroma of fruits too, depend upon the proper selection here? In all my difficult crossing operations latterly, I used the pollen of all the anthers, leaving nature to select for herself.

This suggests to me a matter I may as well treat of here as afterwards, and which is referred to by Mr. Darwin at page 545 of the latest edition of his "Origin of Species," where he holds the sterility of hybrids to be a different case from that of a first cross, the reproductive organs of hybrids being more or less functionally impotent; and for which he shows apparently very valid reasons. Yet I may refer to a pretty well-known hybrid of my own, as affording, in its case, no failure from either of its parents in this respect. The *Veronica Andersonii*, a hybrid between *V. Lindleyana* (mater) and *V. speciosa* (pater), yields seed, perhaps, in larger abundance and of equal fertility with those of either of its parents. Another brood which I raised, between *Veronica decussata* (*V. elliptica*, Hook.) of the Falkland Islands, and *V. speciosa* of New Zealand, bears seeds in equal abundance with its parents, and likewise of equal fertility. These were of course seeds of original hybrids. But I found in another hybrid which I effected many years ago between our own alpine veronicas—viz., *V. saxatilis*, having rich bright blue flowers, and *V. fruticulosa*, having white flowers striated with pink, which I honoured with the name of our honorary secretary, *Veronica Balfouriana*, having blue flowers striated with red—that the seeds of the second generation from it, at least of one whose flowers diverged from the colour of either of its parents in becoming red, no seeds of that red descendant, though tried over and over again in successive years, ever vegetated.

I may now, ere I quit this subject, observe a very singular phenomenon in increased fecundity in seed-bearing of a first cross. When the beautiful and fragrant *Rhododendron Nuttallii* was introduced from Assam into our gardens, I shared, in common with others, a desire to try what could be made of it by crossing with other species—and of its progeny in this way I have two or three broods, some of them now of 2 and 3 feet high. These operations were performed in the spring of 1862. On the 12th January, 1863, I pulled from *Rhododendron Dalhousiae* a seed-pod so crossed with *R. Nuttallii*, the size of which I carefully measured, and found it was $1\frac{1}{2}$ inches in length by 2 inches in girth, whereas the largest normal seed-pod gathered, equally ripened from the same *R. Dalhousiae* at the same time, I found to be only $1\frac{1}{4}$ inches long by $1\frac{1}{2}$ in girth. But the most remarkable thing of all about this cross was that, though the seeds were fully ripened, and in such abundance as I never before saw equalled in the family, and though, when sown, the seedlings came up thick as chickweed, yet every one of them died off in the seed-leaf or second pair. Though they came up in thousands, I could not preserve one of them. Yet, singularly enough, I have raised no end of another brood, obtained by crossing *R. formosum* with *R. Nuttallii* with another hybrid of my own, obtained by crossing with *R. Dalhousiae*. The fertility here was due, I have no doubt, to the infusion of the "blood" of *R. formosum*. As a proof of this, I at the same time sowed the seeds of a cross between *R. formosum* (pure) and *R. Nuttallii*; the seedlings came up in double profusion. Are these results due to a nearer or remoter vicinage of original habitat? for all are Himalayan species, the *R. Dalhousiae* being from the Sikkim, the *R. formosum* from the Khasia, and the *R. Nuttallii* from the Assam or Bhotan ranges.

But I am digressing sadly. My object in the experiments above noted has mainly been to show that nature abhors all alliances in relationship beyond the closest affinities. Members of many genera besides those so close as the well-known instances of the apple and pear, the gooseberry and currant, oh-tunately resist all intermixture by crossing. I have already noticed, in addition, the bramble and raspberry, and I could add many others equally closely allied, but equally intractable. I may return to this question of unaccountable antipathies in a subsequent paper, where I may notice some equally unexpected sympathies between unlikely species, of which I may here note only a single instance.

Having two very distinct species of *Browallia* in my garden, one a shrub, growing from 4 to 6 feet in height—viz., *Browallia Jamesonii*, an orange-flowered species—and another, a tiny blue-flowered herbaceous annual, from 6 to 9 inches high, both from the Andes, it occurred to me to try a cross between them. I made the cross on the *B. Jamesonii*, having previously most carefully emasculated the blooms. The cross was made on the 17th June, 1865. I gathered the seed on the 5th July that year, but the seeds, though well formed, being immature, never vegetated. This cross I mean to try again, for the seeds, though not ripe, were no mere embryos, which often occur in such extreme crosses.

I cannot close this part of my paper without suggesting to others an experiment I intend to attempt myself, if spared, on a small scale this ensuing summer, and that with a view to bridging over some of those gaps over which nature will not of herself be made to leap. I have been again and again surprised how near and even far off allied things will incorporate, by the simple act of grafting, an act by which the sap and every vital principle which sustains the one must now animate both, and yet the two living things so made one will not, in their separate state, unite by any act of crossing yet resorted to. Hence it occurred to me that a union might be tried between the two separate subjects by fertilizing the flowers of the engrafted plant with the pollen of that species which forms its stock. For example, I have several pear-trees engrafted on the common white thorn, which flower and bear abundantly every year. I mean to try how far the pollen of the latter (*Crataegus oxyacantha*) may not fertilize the other, and produce an intermediate. I wish much that others would try what could be done in similar cases. The rationale of this

experiment is strongly supported by a circumstance noticed in Loudon's "Gardener's Magazine," vol. xiv., p. 430, of a male plant of the *Carica Papaya*, a dioecious plant, having borne female flowers at the extremity of the racemes of a male plant, which was accounted for by the fact of the plant having been, two years before, inarched on a female plant of the same species, that part which bore such female flowers having grown subsequent to the act of grafting. The familiar case, too, of the *Cytisus purpurascens* or *Adami*, a hybrid between the common laburnum and *Cytisus purpureus*, affords another striking instance of the influence of the stock on the scion. For when grafted, as it generally is, on the more vigorous laburnum, shoots sometimes of a mixed character, partaking of both stock and scion, and sometimes of the laburnum pure and simple with its proper foliage and flowers, spring out from the branches of the *C. purpurascens*.* Other instances might be given, but for the purpose in view those cited may suffice.

I am yet but on the threshold of a vast subject, with what relates to pure hybridization—i.e., the crossing of one species with another distinct species of the same genus—and the crossing of varieties scarcely touched upon. With some of my experiments in these still ample fields, I may tax your patience in some other paper at a future time.

GRAVEYARD GARDENING.—Improvements are of very slow growth in the metropolis, and in our towns and cities generally. The rottenness of rockeries must rarely be sacrificed for the most patent and desirable of improvements. In one direction, however, there is a change to be observed in this respect; they are "improving" the graveyards, not merely where the tunnelling power of a railway company is brought to bear, but in places untouched in this way, and where the thing is done for mere love of improvement. Evergreen shrubs are proverbially fond of London smut. The visitor to London who observes such matters can hardly fail to be struck with their luxuriance round the church in the Strand, in front of Tattersall's, and many other spots in which they have been planted at some expense. The verdant and luxurious aspect of these places has had its effect upon the churchwardens and powers that be, and accordingly they have set to work to beautify our graveyards. Evergreens are to be substituted for headstones, and lamentable bits of cockney gardening for the memorials of the dead. The most notable instance of this kind with which we are acquainted is around the church in Bishopsgate Street. Tombs and headstones appear to have been cleared out of the way, and all obstructions removed, so that a level surface might be obtained on which to set a few hundred evergreens, which have little more chance of flourishing in Bishopsgate Street than if planted in the Salt Lake. To have one's bones or memorial disturbed for the ill-digested schemes of a landscape gardener is bad enough, but when it is considered that this sacrilege is performed to plant subjects that have no chance of growing, then the wisdom of the change is fully seen. It is true the sculpture in our cemeteries is anything but Greek, and the inscriptions not quite so simple and elegant as those in the Catacombs; but the rudest and most monotonous of them tell of love and death—"where human harvests grow," and to all but the most vulgar minds must be sacred and beautiful. What must be the feelings of those who have had the memorials of friends and ancestors disturbed for such purposes? Why, it is enough to draw an anathema from a less ready rhymist than he who wrote "Cursed be he who moves my bones!" And it is the more inexcusable when we reflect that there is not the least occasion for any mutilation of the kind, and that the most suitable trees for such places are those that would not require any alteration of the ground, and would flourish freely in a town atmosphere. The weeping willow, birch, weeping elm, and a considerable variety of drooping and other deciduous trees are, above all others, suited for this purpose, and might be planted without interfering with the stones in any way. Would the latter look any the worse for being shaded by a beautiful pendulous tree here and there? The fact is, town cemeteries may be made as beautiful as it is possible to make them with vegetation by the use of deciduous trees and shrubs alone; and that, instead of any clearance or levelling being required for the judicious placing of these, they will look all the better for being picturesquely grouped among the irregularities of the ground.—*The Field*.

SKELETON LEAVES.—The following method has been communicated to the Botanical Society of Edinburgh: "A solution of caustic soda is made by dissolving 3 oz. of washing soda in two pints of boiling water, and adding $1\frac{1}{2}$ oz. of quick lime previously slacked; boil for ten minutes, decant the clear solution and bring it to the boil. During ebullition add the leaves; boil briskly for some time—say an hour, occasionally adding hot water to supply the place of that lost by evaporation. Take out a leaf and put it into a vessel of water, rub it between the fingers under the water. If the epidermis and parenchyma separate easily, the rest of the leaves may be removed from the solution and treated in the same way; but if not, then the boiling must be continued some time longer. To bleach the skeletons, mix about a drachm of chloride of lime with a pint of water, adding sufficient acetic acid to liberate the chlorine. Steep the leaves in this till they are whitened (about ten minutes), taking care not to let them stay in too long, otherwise they are apt to become brittle. Put them into clean water, and float them out on pieces of paper. Lastly, remove them from the paper before they are quite dry, and place them in a book or botanical press."—*Dr. G. Dickson in "Hardwicke's Science Gossip."*

* Since writing the account, I have just read of the *Cytisus purpurascens* or *Cytisus Adami*, and stating, as I have done, on the authority of a notice given of it in Lindley and Moore's "Treasury of Botany," of its being a hybrid, I have this morning read another account of its origin in *The Farmer* of yesterday, where, reporting the proceedings of the last meeting of the Royal Horticultural Society, it is stated—"Mr. Leo, Clevedon, Bristol, sent most remarkably dissimilar examples of apples from the same branch of a tree of orange Pearmain, which was a fertile subject of comment at the meeting. The tree was the true variety, and the other samples were of a russety cast, instead of the bright crimson colouring common to the original. Rev. Mr. Berkeley instanced *Cytisus Adami* as a sport of a similar character, which is believed to have been produced by grafting *Cytisus purpureus* on the laburnum, and by some accident one cell of the stock and one of the graft having each become divided, and then united together, the result had been a plant partaking of the nature of both. Mr. Berkeley suggested that it would be most interesting to know the stock upon which the orange Pearmain had been worked." Whatever be its origin, the facts I have stated, and which probably many of us have seen with our own eyes, of the same tree producing three kinds of flowers, and two, if not three, different kinds of leaves, there can be no doubt of these having resulted from the operation of grafting. The two kinds of fruit, too, of the Pearmain seem to have arisen from the same cause. And it would seem, also, that many of the sports we see and hear of in roses, in changing colour, and betaking themselves to a climbing habit, are due to the same cause.

DISTINCT AND HANDSOME HARDY PLANTS FOR THE FLOWER GARDEN.

The taste for varying the surface of the flower garden, and for adding to its interest and character by using plants of a nobler type than we have already generally done, is sufficiently developed to warrant us in assisting it, and pointing out the most desirable for such purposes. There are a great many recommended, a great many used; but, as usual, the really meritorious are in a minority. It is a dangerous and a useless thing to place tender plants in the open air, for the sake of producing such an effect as may have been seen at Battersea; and even many there placed in the open air have no chance of looking to any advantage out of a hothouse in this country, and here we would particularly instance the Bananas. On the contrary, nothing should be used but such things as will stand our climate without injury, or grow freely and luxuriantly in it. Of course hardy plants are the very best to use for this purpose, but as yet we are far from having a sufficiency of these of the precise type that is required, and so we must draw upon tender and half hardy subjects for the present, and be very careful in doing so; for nothing is more lamentable than to see an English garden with tender plants perishing from cold in the middle of summer. The climate and altitude of the garden should also be considered, for it should be well known that you may grow many things in the open air about London and southwards which will barely exist, if at all, in the north or north-west. Therefore, the position and capabilities of the place are the first things that should be taken into consideration. It by no means follows that because it may prove cold and uncongenial to many subjects which have afforded a good effect about London, that we should rest satisfied with the tame aspect of such. We quite believe that there is no part in these islands for which fine, verdant, and distinct-looking plants will not eventually be found, if they be not in the country already. Why, even supposing we could not find any suitable among the humble and herbaceous subjects, how much may we not do towards diversifying the flower garden by the use of those elegant dwarf, green, and tapering conifers in the way of *Retinospora* and *Cupressus*, which are hardy and presentable at all seasons. There is hardly any limit to their extent and beauty; and, if it be urged that some of them might grow too big for such positions, the answer is, that they may be removed at pleasure and taken to a more suitable position. We do not suggest the placing of such in intimate association with the transient-flowering plants, but so that they will contrast with and tend to relieve these. There is nothing more intolerable than a flat wide flower garden closely packed with small or large beds, and so arranged that you see nothing but a level sheet of colour. We have seen such changed to scenes of beauty by making the beds a subordinate feature to the turf embellished with choice shrubs, &c., and have no doubt that a like change is required with many flower gardens. But we will at once commence with the most difficult part of the subject, and treat of

HARDY PLANTS THAT FURNISH A "SUB-TROPICAL" EFFECT.

Among all the plants ever introduced to this country, you cannot surpass in this direction the various kinds of *Yucca*, or "Adam's Needle" as it is sometimes called. There are several species hardy and well suited for flower-garden purposes, and, more advantageous still, quite distinct from each other. The effect afforded by these *Yuccas*, when well developed, is equal to that of any hothouse plant that we can venture in the open air for the summer, while they are hardy and presentable at all seasons. They may be used in geometrical "English" or any other style of garden, or may be grouped together on rustic mounds, or in any other way the taste of the owner may direct. The best, perhaps, considering its graceful and noble habit, is *Y. recurva*, which is simply invaluable in every garden. Old and well established plants of it standing alone on the grass are pictures of grace and symmetry, from the lower leaves which sweep the ground to the central ones that point up as straight as a needle. It is amusing to think of people putting tender plants in the open air, and running with sheets to protect them from the cold and rain of early summer and autumn, while perhaps not a specimen of this fine thing is to be seen in the place. Than this there is no plant more suited for planting between and associating with flower beds. Next we have *Y. gloriosa*, more pointed in habit and rigid in style, and also large and imposing in proportions. Lacking the grace of *recurva*, it makes up for that to some extent by boldness of effect, while, like the preceding, it sometimes sends up a huge mass of flower. Then there is *Y. glaucescens*, with a sea-green foliage, and rather free to flower, the buds being of a pink tinge, which tends to give the whole inflorescence a peculiarly pleasing tone. This is a first-class plant. *Y. filamentosa* is smaller than these, but given to flower with much vigour and beauty. There are other hardy kinds, but they are too difficult to obtain to make it worth while mentioning them here.

Next to the *Yuccas*, as effective hardy plants, we would certainly

place the *Pampas grass* and the *Arundo conspicua*. The *Pampas grass* is perhaps as well known as any other garden plant, but people are too apt to stick it in some out-of-the-way place, which may perhaps be denominated its "proper" one. Doubtless you cannot have a better plant in a wood or wild glade, or by the margin of a stream, than the *Pampas*; but why not use so noble a subject more extensively where it is likely to be more seen, and where its graceful and noble habit and splendid silvery plumes may help to diversify and beautify the flower-garden? It need not of necessity be placed in a position or positions to confuse the plan of the garden, or interfere with the neat arrangement of the minor plants; but there are few places in which it may not be made an admirable adjunct, and worked in with great effect on the outskirts of the flower garden. Give it in every case a capital position in which to grow, or, in other words, the best soil, and the deeper the better. It dislikes a very exposed position, where its leaves get knocked about and much hurt by the wind; but nevertheless we may often find it necessary to plant it in such, and by tying up the leaves in winter, and spreading some cocoa-nut fibre about its base, it may escape injury. Probably it would show to more advantage on an elevated place than any other, and on such it will thrive perfectly if sheltered by shrubs. We have noticed its development strongest of all in well-sheltered hollows. But it will grow anywhere to an ordinary size. With it we would associate *Arundo conspicua*, a smaller grass, though in somewhat the same style, and flowering earlier. This makes a handsome object in the midland and southern counties of England, and may also in the north, though we have no experience of it there. With these and the *Yuccas*, bold groups and specimens of the *Tritomas* may be associated with the best effect. We talk about sub-tropical plants, but what can be more suggestive of all that is noble and beautiful in vegetation than the fiery spikes of these pushing up till almost or quite the end of the year, and the grand silvery plumes of the *Pampas*? Assuredly nothing ever seen in the flower garden. The best kinds of *Tritomas* are *glaucescens* and *grandis*; the last being late and very tall, the first an abundant autumn bloomer. Plant in deep good soil, and do not disturb them oftener than you can help.

Next in utility among thoroughly hardy subjects are the various kinds of *Acanthus*, with large shiny leaves, and a hardy, vigorous constitution. The best are *A. lusitanicus*, a comparatively new one, which is beginning to find its way into English nurseries, and *A. spinosissimus*, which is far from common; but, indeed, any of the hardy members of the genus that we can obtain are capable of furnishing a nobler leaf effect than many tender plants placed out of doors for that object. But decidedly the best is *A. lusitanicus*, a noble-growing kind—the leaves very large, and of a dark polished green. It is perfectly hardy, and the leaves retain their glistening vigour till cut off by frost. But though hardy, if kept over the winter in pots, it sends up a fine crop of leaves, and may thus be used with effect as an in-door greenhouse plant. In the south of England and Ireland the New-Zealand flax, *Phormium tenax*, sometimes makes a nice plant, and is worth a trial; so does the elegant Bamboo, *Arundinaria falcata*, and the coarser though handsome *Arundo donax*. And some of those green and graceful *Dracenas*, which are such fine things in a conservatory, may be grown in Devon and Cornwall and the south of Ireland; indeed, we have seen *D. australis* do well in Devon; and in a vase in the garden of the superintendent of Alexandra Park, at Muswell Hill, a plant of *Dracena indivisa* has stood out for some winters past and grown well every summer. But such things have little or no chance in the north, where it is fortunate, however, that those beautiful dwarf and tapering conifers may be grown with ease. Such things as *Thuja aurea*, nice young specimens of *Thujopsis borealis*, and various kinds of *Cupressus*, *Retinospora*, &c., are fortunately as hardy as we could desire, and nothing can be more suited for diversifying the flower garden.

Of all plants with finely dissected leaves, *Ferulas* are the best—they are even more elegant than the finest ferns—but not easy to be got in nurseries, and, indeed, often the only way you can obtain them is from seed, or from a botanic garden. They come up in winter, and look very attractive through the spring and early summer, but fade too soon in autumn, and are not therefore suited for placing with summer flowers, but rather about the margins of shrubberies, &c. There are many other things in the same order distinguished by beauty of leaf, from *Meum athamanticum* upwards; but they are scarcely to be had in "the trade." If it were bulb-planting time, we would occupy some space in reminding the reader that a lot of tall and noble Lilies, like *tigrinum*, *Fortunei*, and *excelsum*, are grand things for producing a fine effect in autumn, either in isolated beds or here and there among roses or shrubs; but we must adapt our essay to the wants of the time, and leave those alone at least till autumn.

We wish to direct attention to *Thalictrum minus* as being capable of affording, when fully exposed in the flower garden, almost precisely the same effect that the common Maiden-hair fern (*Adiantum cuneatum*) does in the houses. That it certainly will

do when established; and those who have planted young specimens, or are about to do so, should not disturb them for some years, as young weak plants are not big enough to afford the effect we desire. We have also found that another perfectly hardy plant affords a fern-like effect of a different though perhaps equally useful character. The *Thalictrum* has spreading composite leaves, like the Maiden-hairs, but the plant we now wish to bring under notice has pinnate leaves, reminding one of the small *Blechnum* type of ferns, but prettier than any of that group we can call to mind. It is the rather common English *Spiraea* or Dropwort, *Spiraea filipendula*. Its deeply-toothed and fresh green radical leaves look almost exactly like those of a fern when planted in line, and the flower-stems pinched off as a matter of course. It is a common plant in England, though not in Ireland. There is a double-flowering variety, not uncommon in gardens, which, so far as we have observed, is a little dwarfer than the single one. There need be no more doubt about this than about the *Thalictrum*; we have proved both to be highly suitable and elegant as dwarf edging plants.

Of other herbaceous plants likely to do good in this way, one of the very best is *Eryngium amethystinum*, a fine thing, with its flower-stems of the deepest and finest blue, and the flowers of which may be kept over the winter; and *Statice latifolia*, for the sake of the great distinct mass of bloom it produces in the autumn. In mild places in the south, or along the coast, wherever the graceful bamboo, *Arundinaria falcata* would do, it should be planted. Perhaps the most striking of all hardy plants in this way, both for grace and colour, is the variegated variety of the Great Reed of the south of Europe, *Arundo donax variegata*. This may be grown over the greater part of England as a flower-garden ornament, and kept over the winter in the ground, too, by covering the ground round its collar with some refuse stuff like cocoa-nut fibre or coal ashes, and over that, as it is a beautiful and choice plant, winding a bit of old matting round the stem. It does not grow near so high as the green kind, being doubtless dwarfed by the brilliant variegation it displays. We know of nothing more beautiful in the centre of a not over large bed of choice things than a plant of this. We have preserved it as above described in stiff cold soil; on warm and good soil there would be no trouble with it. Another good subject, though but an annual, requiring much the same treatment as the Castor Oil, is the new variegated *Japanese maize*, a really graceful and pretty thing, which merits general culture. It is very pretty in the flower garden, or any other position in which you can use a prettily-striped plant. If you are fond of huge-leaved things, try and get a root or two of *Rheum Emodi*, a fine scarce kind of Rhubarb, with grand leaves, having red veins; and *Crambe cordifolia*, an immense kind of Seakale, with great green leaves. These would be fine for the composition of bold groups, and if among such were sprinkled the bolder kinds of Lilies, the effect in the autumn would be very fine. To wind up, *Cynara horrida*, a near relative of the "French Artichoke," is very fine, with ample silvery leaves; and the great *Gunnera scabra*, found by Darwin, and mentioned by him in his "Voyage," comes to a surprising size if allowed deep soil, plenty of shelter, and water. *Phytolacca decandra* is large and conspicuous, but has scarcely quality enough. *Funkia Sieboldiana* is very fine for a rich light or peaty soil; and *Craspedia macrocephala* is a lovely silvery plant, with soft hemispherical flowers of the purest yellow—one of the handsomest plants in existence. *Silybum marianum* and *S. eburneum* are biennials of very marked aspect. *Salvia argentea* is the handsomest of all large silvery-leaved plants for the flower garden, its leaves spreading out on the ground like little blankets. *Helianthus argyralis* is a very tall composite, with recurved leaves, growing eight or ten feet high; and *Artemisia annua* is a green wormwood, which forms a pleasing, dense, fresh, and pyramidal bush; and any of the *Onopordons* are valuable from their thorough distinctiveness and the fine effect they offer when contrasted with our ordinary green shrubby vegetation. The best position for them is on the margin of a shrubbery or plantation, where they will sow themselves, and where, when the young start up into stem, they must all be cut away with a hoc or spade, with the exception of two or three individuals at any given point. YUCCA RECURVA.

THE SALVIA AND VARIETIES.

This is a very useful class of plants, either for growing as plants in pots, for ornamenting the greenhouse when in flower, or for planting out in beds or borders, for enlivening the flower garden during the late autumn months with their many shades of scarlet and blue flowers. What blue is there to surpass in richness of texture and colour *Salvia patens*? and nothing makes a finer bed. It is true it almost grows too tall, especially in showery seasons, so as to somewhat unfit it to harmonise in the arrangement with the heights of the generality of our bedding plants. But this fault can be got rid of by planting it in a single bed—that is, in positions where matches of colour and height are not requisite—though, by the bye, we can, as with other plants, have two beds instead of one, if it be required, they should correspond. Being a tuberous-

rooted plant, they can be taken up in the autumn when done flowering, and stored away the same as dahlias. If the roots are potted early in the spring and plunged in heat, they will throw up a great number of shoots, and as these are taken off so will the quantity keep increasing, so that from a single root you may strike a goodly number of plants by the time we usually commence bedding. They are more difficult to propagate in the autumn, as every shoot emitted has a tendency to produce flower, and the wood becomes too thready or hard; so that out of the many you may insert in pots there will be but few rooted. *Salvia patens alba* requires exactly the same treatment. I cannot say that as a flower I admire it, because it is not a pure white, although named *alba*, it having mixed up with its colour too much of the strain of its parent, which gives it the appearance of a dirty white, although it makes a very desirable change when growing with others.

Salvia Grahamii.—This is a very superior variety for winter decoration. It partakes more of a shrubby habit as compared with those already mentioned. It has smaller leaves, and throws up well above the foliage some fine erect spikes of bright crimson flowers, which with care last a long time in perfection during the dull months of winter.

Salvia splendens.—I remember the period when you would scarcely behold a conservatory or greenhouse, during the late autumn months, without observing quantities of this variety in bloom mixed with other plants, its fine, clear, bright coloured scarlet flowers being pushed forth somewhat pendant fashion from the points of the shoots. Of all the varieties I am acquainted with, this requires the most careful management. When in flower in the conservatory it must not be subject to damp, or you will soon lose the flowers. The plant at this stage of its growth delights in a rather dry atmosphere, but not that kind which is created by fire-heat, although a gentle warmth given now and then would be beneficial. Another destructive enemy to guard against is the red spider, and this plant is very liable to be infested with it. The best prevention is to encourage a free and vigorous growth during the summer months, with frequent syringing, not to allow them to become pot-bound till towards the period of their flowering. The more healthy plants generally are those which are struck from cuttings obtained from old plants that have been put in heat early in the spring.

Salvia Gesnerifolia.—This is another excellent variety for winter flowering, producing a profuse number of rich crimson coloured flowers. It is a very luxurious-growing plant, and is not so liable to the attacks of insects as the last-named variety. Its deep green healthy coloured foliage contrasts well with its bright flowers. We cannot grow too much of it for the purpose of winter decoration in the conservatory, where we have the space at our command.

Salvia fulgens.—This rapid-growing variety is well adapted for large beds or specimens in the border. The only drawback to their general culture for that purpose is, that they do not commence flowering till late in the autumn, although you may previously give every possible encouragement to the production of a vigorous growth. Should frost come upon us quickly, the consequence would be that their beauty would be suddenly destroyed; yet, withal, I would advise its being planted freely, for, should the autumn be favourable, it will, with the dahlias, add much to the floral beauties of the garden at that season. About twenty years ago, when living at Clapham Park, I planted this variety alternately with *S. splendens*, round the outside border of a very large bed, in which rhododendrons, azaleas, and other American plants were growing, and the production of flower and growth surpassed anything I ever saw in connexion with these plants before or since—an evidence that their roots are partial to peat earth.

Salvia chamædryoides.—I have lost sight of this most beautiful variety for several years past. I made some inquiries respecting it lately, and was informed that Mr. Salter, of the Versailles Nursery, Hammersmith, had it growing. It is very dwarf compared with the other sorts, and not so succulent in its habit, but the flowers are an intense rich blue. I may compare it in colour to the flowers of that lovely greenhouse plant *Hovea Celsii*.

There are many other desirable varieties of *Salvias* I might enumerate, but with the culture and habit of the above I am more conversant than with any others. JOHN F. MELROY.

Calendar.

WORK FOR WEEK COMMENCING MAY 4.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Sow beet for a winter supply. Thin beets already up, and if any gaps in the drills, fill up by transplanting the thinnings in showery weather. Sow Walcheren broccoli, collards, cauliflower, endive, kidney beans, lettuce, leeks, spinach. Plant out marrows, ridge cucumbers, capsicums, tomatoes, celery, and anything that may be strong enough from seed-beds of cabbage and winter greens.

POTATOES are pushing with vigour everywhere. Hocking between is of immense benefit, and a little earth may be drawn to the stems, but the heavy moulding up to which they are subjected on the orthodox plan of cultivation is decidedly injurious. If any remain to be planted, get

them in without delay, and if a sprinkle of manure can be afforded to put at the bottom of the trenches it will help them to start freely.

WINTER GREENS of all kinds to be pricked out from seed-beds as soon as large enough to handle. Choose showery weather, and put them on good ground.

KIDNEY BEANS, both dwarf and runners, to be sown for main crops.

SEAKALE is pushing into flower, but unless seed is wanted the flower-heads should be nipped out.

SPINACH is usually sown thick, and a good way to thin it is to wait till the leaves are an inch long, and then draw the plants in little bunches. They make a very nice dish, if the cook will take the trouble to cut off the roots and remove the bottom leaves. But if not wanted, thin the crop and throw the thinnings on the rubbish heap. If left much crowded, it runs into flower quickly.

PARSLEY sown now will be up soon. Sow on rich light soil, and transplant as soon as large enough to handle. This method will ensure finer produce than leaving the plants to stand where sown, and those with richly-curved leaves can be selected as soon as they are a little advanced beyond the seed-leaf.

CUCUMBERS in TRENCHES planted out at once, and protected with hand-glasses, will produce better crops than if kept in pots till they spindle away their strength. Make the trenches two and a half feet wide, and one foot deep. Fill it a foot above the surface with hot dung that has been twice turned, or a mixture of leaves, straw, and grass-mowings. Three days afterwards put on six inches of soil, and leave it a couple of days; then put on three or four inches more soil, and plant. They will then have a steady bottom-heat, and if sheltered for a time will do well.

TURNIPS are not much in demand till autumn and winter, but this is a good time to sow a small breadth for summer supply. Use manure abundantly, and after sowing sprinkle over the bed a little lime or soot. This usually prevents the eating-off of the young plant by the fly, as it is only while in the seed-leaf that turnips are in danger.

SURFACE-DRESSING between growing crops with wood-ashes, soot, guano, or any good artificial manure, such as "Standen's Amateur's Friend," is far better than the use of manure-water in all open-ground cultivation. Indeed, in most good gardens pot plants demand all the liquid manure that can be got; but where there are capacious sewage tanks, and a good supply, it may be used freely to roses, strawberries, cauliflowers, rhubarb, gooseberry-trees, hollyhocks, and other gross-feeding plants. It should always be understood that weak manure water in large quantities is to be preferred to strong manure in small quantities.

WEEDS are springing up in abundance everywhere. Brisk hoeing will stop them for a time, and save much after-work, and the spreading of their seeds, while the crops will be benefited.

LIME-WATER should be used quite clear, and as a given bulk of water will only take up a certain quantity of lime, it cannot, if clear, be too strong. It should be prepared a few days in advance to ensure its being good. A pound of lime is enough for four gallons, but if more is used, it only forms a sediment, and does no harm.

Flower Garden.

BEDDING OUT.—Choose dull dry weather if possible, while the ground is moderately moist. Have the plants pretty dry, by withholding the water the day they are to be turned out. By watching the barometer, and getting all planting done just before rain, much labour in after-watering will be saved.

IVY does not generally figure as an item in gardening calendars; but it may be well to remind our readers that now is the best time to propagate it. The plants struck from young shoots now will have tremendous vigour if well managed. In "Rustic Adornments for Homes of Taste" is a description of a mode of growing ivy to form umbrellas and canopies for use at fêtes and festivals. Now is the time to strike cuttings for the purpose, and take them up in clean rods to the required height at which they are to be stopped to form a head. These should be grown from the first in pots, and never be put in the open ground until discarded for the purpose for which they were originally grown.

HERBACEOUS PLANTS throwing up their flower-spikes will in many cases require to be neatly staked to protect them from high winds and heavy rains. This the more needful where herbaceous plants are mixed with shrubs in borders, as in such cases they always push their heads of flowers out in an oblique manner, and this prepares them to fall over when heavy rains occur.

RANUNCULUSES AND ANEMONES.—These want plenty of water while their flower-buds are swelling, yet we do not like artificial watering. First give the beds a good soaking in the evening, using a water-pot with a coarse rose on, and do not be afraid as to quantity. The next night have ready a hogshead or so of lime-water, and use this without a rose, pouring the water from the spout of the pot put close to the ground, so as to wet the leaves as little as possible. By this process they will be greatly benefited, and will not want water again this season.

GRASS LAWNS require much attention now. Daisies are in bloom, and there can be no difficulty in finding them. Everybody is in want of a specific for their eradication. We have said so often that we are half afraid to repeat it, though we must, because inquiries are repeated, that spudding them out is the only effectual means of getting rid of them. It is a sheer matter of time and patience and back-ache. Where there is a full complement of work for the gardener, there ought to be no complaint about daisies on the lawn, for if he is doing his duty his hands are over-full now, and while he is spudding daisies a thousand important things will go to ruin. We have no faith in putting boys and girls to this work, though no doubt half a dozen youngsters trained to the work would be useful, and earn more than their salt in spudding them out. The best tool is a large strong knife with a stout horn handle, and the way to use it is to heave up the daisy gently, and draw it out by the roots complete, then tread the earth back. In many places, daisies thrive and grass does not; it is a question, then, seeing that, barring the flowers, daisies are close-growing and evergreen, whether it is not better in the end to leave them alone, and silently sing the ditty of "We must all be contented, and bear with the ups and the downs;" and, by the way, daisies are rarely seen on downs; it is on the flat fat loams they prosper. Generally speaking, lawns require plenty of roller and machine now. New grass must be tenderly dealt with, and much as we love machines, and enjoy the using of them, we prefer the scythe for the first few mowings of lawns newly made from seed.

ROCKERIES may be brightened up now by turning out in suitable places such plants as Saxifrage, Phlox subulata, Dianthus fragrans, Antirrhinum,

Columbines, Festuca glauca, Elymus glauca, Crimson Thrift, Campanula garganica and rotundifolia, Potentillas, &c. At the nurseries where herbaceous and alpine plants are grown in variety, charming selections may be made at very low prices; and as many of the plants are now in bloom, the future effect of the selection can be judged at once. Ornamental grasses contribute largely to the decoration of rockeries, if judiciously used.

Fruit Garden and Orchard House.

FRUITS RIPENING under glass must have a comparatively dry air and plenty of ventilation, or they will lack colour and flavour. If a few fine fruits are preferable to many of an inferior kind, let those that take the lead swell off and ripen, and remove the greater part of the remainder. This practice is of great importance in the case of strawberries, as succession bunches coming on while more forward heads of fruit are ripening retard the progress of the latter, and prevent them attaining to their full size and flavour.

ORCHARD-HOUSE TREES are now swelling their fruit, and need the help of manure-water. Use it rather weak at first, for fear of causing stone-fruit to fall. After two or three doses, alternating with plain waterings, increase its strength. Stone-fruits not yet beginning to swell should be kept without it for the present. As the mulch in the pots has now become dry and chippy, take it out, and replace with fat, half-rotted dung. Use the syringe freely, and with force, to wash off withered blossoms. Give air night and day, and pinch in to the third or fourth leaf from the base all the side-shoots, to cause a production of fruit-spurs. If the shoots have got too far, and the thumb-nail will not cut them clean through, use a small knife or scissors. Wherever you see a curled leaf, search for the cause of it, and you will find either grub or fly, with either of which deal promptly.

Greenhouse and Conservatory.

SINGLE-FLOWERING CHINESE PRIMULA.—The single varieties are raised from seed, sown from May to July, according to the period at which you wish your plants to be in perfection both as to flower and foliage. If you wish to have them at Christmas, sow in middle of May; if in February, sow in June; if in March and April, sow in July. The compost we usually sow our seed in is composed of fibrous yellow loam, old leaf-soil, and silver sand passed through a fine sieve, and well incorporated; three parts loam and one part leaf-soil will be the proper proportion, using sufficient sand to keep it porous. If leaf-soil cannot be procured, peat will answer the purpose, but it is not so good. The pot we use is a five or six inch one, filled one-third of the way up with broken crocks for drainage, then fill with the compost nearly to the top, water with a fine rose thoroughly, sow the seed, and sprinkle a little silver sand on the top, barely enough to cover the seed; cover the pot with a pane of glass, and place it as near the light as possible in a shady part of the greenhouse or a frame, shading from the intense rays of the sun. In two or three weeks you will have a nice crop. As soon as large enough to handle easily, transplant singly into small thumb-pots, using the same compost, and place in a close cool frame for a week or ten days, gradually giving air to harden the young plants, and prevent them from drawing up weak and spindly. As soon as well established, repot into their blooming pots, using the compost in the same proportions, only passing it through a coarse sieve instead of a fine one, adding a small quantity of well-decomposed manure—the older the better. If you have a half-spent hotbed to stand the plants on at this potting, it will assist them materially, as the grand secret is to keep them growing from the time the seed germinates until they are in bloom; allowing them to become pot-bound or checked in any way, will so injure your plants that a very unsatisfactory bloom will be the consequence. About the middle of September, they should be placed either in a nice warm greenhouse, with ample means for ventilation (by this we don't mean cold draughts of air, but the ventilation so arranged that the air shall be heated to the temperature of the house before coming into contact with the plants) or a pit with the same command for admitting air on all favourable occasions. The Chinese primrose requires the treatment of an intermediate house through the winter months, in which the temperature should not be less than 45° or exceed 60°, unless when there is sun, when 5° for an hour or two in addition would do no harm. Another point to be remembered is, when watering the plants, the water should be of the same temperature as the house or pit in which the plants are kept. With a little care the plants will progress rapidly, and as soon as the flower-spikes can be seen in the heart of the plant, weak manure-water should be given twice a week; only it must be weak, and should contain soot in solution if possible, as this, with plenty of light and air, will give a fine colour to the flowers, a great addition, and makes the plants of more value. It is better to sow seed and raise young plants of the single varieties annually, although, if a very fine variety has been obtained, it may be propagated and grown from year to year in the same manner as described for double varieties.

DOUBLE-FLOWERING CHINESE PRIMULA.—The usual way of propagating the double varieties is by cuttings or splitting up the old plants. After blooming, the plants require a season of rest (say a month), after which, if kept close, they will grow freely, and produce plenty of cuttings. These should be planted in single pots (thumbs); the end of the cutting should be cased entirely in silver sand, and placed in a mild bottom-heat. In three or four weeks they will be rooted sufficiently to be repotted into a four-inch or five-inch pot, taking care to keep them growing without check, and as soon as rooted to the side of the pot, again shifting into a larger one. In this way fine plants can be grown in one season. To obtain, however, a fine specimen, instead of cutting the plants to pieces for cuttings, repot the whole plant at once into a five-inch or six-inch pot, taking care in every stage to well drain the pots, and when rooted nicely, pot into a 24-sized pot (eight inches), or larger if required, although it will be well never to over-pot any plants, as they will not make growth so quickly or so freely as when given a moderate shift. To grow primulas successfully, they must have no check from the first start, and avoid the two extremes, neither too cold nor too hot an atmosphere, but the happy medium, usually termed an intermediate house, 45° to 50° by night, ranging from 55° to 65° by day, but not the latter unless by sun-heat. Water carefully, neither drenching the plants nor allowing them to flag, and you may expect some recompense for your trouble. These few hints will apply more or less to all soft-wooded plants, only they do not all require an intermediate house. A little practice will, we trust, with these remarks assist our readers in the cultivation of the primula and other useful spring flowers.

LAPAGERIA ROSEA.—This is a good time to plant this glorious climber. Lapagerias from layers cannot always be depended on; but Lapagerias from seed are as sure to grow as Virginian creepers, give them but the proper soil and suitable conditions. In a pot, Lapageria is like an eagle caged: it must pine and die—its doom is upon it. The only way to be safe is to plant it out in a capacious bed of peat raised above the level. If we could choose all our conditions, we would train the plant up a back wall with a west aspect, in a roomy airy house heated by hot water—just enough to keep frost out. The bed should go right across the house, and be of any length, from ten to twenty feet or more. It should be three feet wide, two feet deep, and be kept up with a brick wall in front. In any case, the plant ought to have a depth of eighteen inches of peat, and a surface of border equal to twelve square feet, which will allow for six feet of length and two feet of width, and in less than that bulk of earth we should not expect to make much of it. Supposing the bed to be two feet deep, there may be six inches of hard rubble at the bottom, and the rest filled up with peat of a gritty nature—such as that from Wimbledon or Shirley; but a greasy peat of a strong character would require a fifth part of its bulk of small pebbles added, say clean shingle of the size of hazelnuts and less. Now with this bed there is another help wanted, and that is abundance of water. As to temperature, the plant requires much the same treatment as a Cape heath—to be kept airy at all times, protected from frost, but to taste as little artificial heat as possible. Of course, if it is not possible to have a run of water, there must be plenty of water supplied by hand labour, or by a hose. It need scarcely be remarked that the front of the bed may be used as a stage for pot plants, provided they are stood on empty pots inverted, both to keep the plants from rooting through into the damp peat, and to prevent the peat getting pasty and sour, which it is sure to do if the atmosphere is excluded by covering the bed with pots. But the best way to treat the surface will be to plant it all over with two-inch lengths of *Lycopodium denticulatum*, six inches apart; these will meet, and form a dense carpeting of most delightful verdure, and do no harm to the roots of the Lapageria. As to training and pruning, we apprehend the cultivators of this beautiful climber will find no difficulty.

CAMELIAS FROM CUTTINGS.—This mode of propagating is not recommended, for camellias grafted or inarched on seedling stocks are preferable to plants on their own roots. The best time to take cuttings is when the young shoots of the season are just getting ripe. Then cut off the young shoots at the fourth joint from the top, that is, to have cuttings four joints long. With a sharp knife trim away the wood of the internode by a horizontal cut close below the lowest joint, and from that and the next joint above remove the leaves. Fill some large shallow pans with silver-sand, and dibble in the cuttings pretty close together all over, and place over them a bell-glass. They should be kept just damp enough to preserve them in a fresh state; if at any time very wet, the cuttings will perish, and so long as moisture condenses on the glass, the sand may be allowed to get nearly dry before it will be useful to give water again. Let them have air every day for a few minutes, during which time the glass can be dried. If there is any probability of the sun shining on them, cover the bell-glass with paper, or smear it all over outside with a thin wash of clay and water. For at least four weeks they should be kept thus in a cool place, and with very little moisture. They will by that time have formed the necessary "callus," and may be removed to a mild hotbed, where they will have a bottom-heat of about 65°, or from 60° to 70°, and not more. They will require more moisture now, and frequent dewing of the leaves, but care must be taken not to rot them by excess of moisture. When rooted, put them off in pure peat, with a fifth part of silver-sand added, and shut up warm till they have made a good start, then lower the temperature and give air, and as soon as hardened treat as old plants.

HYDRANGEAS.—Our own mode of growing this fine plant is very simple and successful; by it we have handsome plants, with huge heads of bloom from the beginning quite to the close of the summer season, and these we group as pot plants about the walks, near garden-seats, and to decorate approaches. In May a number of cuttings are taken from the lower parts of the stems of strong plants. We prefer young shoots with four or five joints, not more than five, and perhaps preferable with only three. The strongest wood may be used, and will be sure to root, but small young cuttings make the best plants. The cuttings have the two lowest leaves removed, and are potted singly in thumb-pots in a mixture of leaf-mould and peat, with a very little sand. These are all placed on a moist bottom-heat of not more than 60°, either over a propagating tank, in a frame over a dung-bed, or in a propagating case. They require to be kept moderately moist, and will bear to be closely confined until they form roots. Never having seen a case of damping-off, though we have struck thousands of cuttings, and in various ways, it does not seem needful to warn the cultivator on this head. However, let air be given moderately after the lapse of a week, and thenceforward increase the supply, so that by the time the pots are filled with roots the plants will be hard and thrifty. When propagated on a large scale they may be dibbled into wet sand, placed over a tank or dung-bed; but we prefer to pot them singly at first, as it is a decided gain in the end. When the thumb-pots are full of roots shift to 60-sized pots, using a compost of peat, leaf, and loam from rotted turfs, equal parts of each; keep them in the greenhouse or warm pit; water frequently overhead, and at the root; give plenty of air, and keep the plants near the glass. When these pots are full of roots, shift to two sizes larger, that is, into pots of six inches diameter, the compost for this shift to be strong turfy loam, full of fibre; turfy peat, all the dust and fine black powdery part removed, rotten dung and leaf-mould, equal parts; no sand. For the drainage of these pots we use only one large oyster-shell, placed over the hole in the pot, hollow side downwards. The plants are shifted into those pots without breaking the balls of earth formed in the 60's, and are at once placed on a bed of coal-ashes, or a hard pavement in a shady place out of doors, or plunged to the rim in a bed of cocoa-nut refuse. They have abundance of water, and before the end of October they have attained to a considerable size, and have ripened plenty of hard flowering wood for the next season. We neither stop nor tie, but allow the branches to fall over as they please, which gives the plants a graceful contour, far preferable to that produced by any kind of training. The plants are housed at the end of October. A cold pit suffices for their protection, and they have a little water occasionally, and are kept clean as they lose their leaves. In case of severe weather, a little care must be taken to prevent them being severely frosted.

AZALEAS AND CAMELIAS making their new growth to have abundance of water, and to be kept in a close pit, shaded; and water to be frequently sprinkled about, to cause a moist atmosphere. Camellias have not

yet grown much this season. As the terminal bud forms, reduce the supply of water, as if they are kept in too free a growth after that the bloom runs away in a new leaf growth. Leggy plants will often throw out shoots if the stems are tied up in moss kept constantly moist.

CAMELIAS growing freely will be seriously injured if exposed to the full blaze of the sun. Shade them in some way, and keep the atmosphere of the house moist by sprinkling water on the paths, stages, &c.

FUCHSIAS may be stopped again to promote a dense compact habit. Plants lately struck will now want a shift on. This is a good time to pot on the whole batch of plants from spring cuttings, as the houses are being emptied of the bedders, and there will be room for them.

PELARGONIUMS that were forced for early bloom will be getting leggy, and their flowers are now scarcely wanted. Set them out of doors in a hot place—near a boarded fence or wall, for instance, in the full sun; keep them regularly watered, and allow them to bloom as they please, and make them useful for supplying cut flowers, and as soon as they begin to look worn out cut them down, put in a few of the young shoots as cuttings, and when the old plants have started nicely re-pot them for next season. It is best not to shake them out, as is usually done with Pelargoniums for summer flowering, but to remove some of the old soil and put them into pots a size larger than they were in before. This promotes a vigorous growth and a good foundation for the next crop of flowers, without much check, and they are thus better prepared to form flower-buds in time for winter bloom. If trusses show in autumn, which is quite likely, pinch back the shoots until within eight or ten weeks of the time of requiring them in bloom. The general stock of young plants will be greatly benefited by a shift on now. Specimens coming into bloom must never lack water. Give them as much sunlight as possible, but shade as soon as the flowers open. Pelargoniums that are knotting for bloom freely may be aided by weak manure-water; but if there is a rank growth and little show of bloom, manure-water will do more harm than good. Give air abundantly on fine days, and syringe all the hard-leaved kinds overhead until the blooms begin to expand, then discontinue it. Varieties with soft leaves are less likely to benefit by syringing.

RHODODENDRONS that have been forced must not be flung into odd corners out of doors, as is usual with plants that have done their duty well. Keep them rather close in a cool house, and sprinkle frequently, giving abundance of water also at the root, to ensure a free growth. By this method they will form their flower-buds early, and may be put out to harden preparatory to forcing again.

CINERARIAS are going out of bloom, and will be tossed wholesale on the muck-heap. If intending to save any, or if the collection consists of named kinds, cut them down and remove to cold frame, and take care of them, and wait for suckers. The sooner these are obtained the better, as they do not flower so early as seedlings, and of course it is a help towards early flowering to have them early potted.

ERICAS AND EPACRIS that have flowered will do better now in cool airy pits than in the greenhouse. When houses are built specially for heaths, provisions are made for affording them abundance of light and air. If they are kept close, and mixed up with soft-wooded plants, they must be unhealthy. Shift on young stock, and shade after the shift; take care that none of the plants get dust-dry; remember rather that there are but few of the tribe but will at this time of year derive benefit from abundance of water.

SUCCULENTS are now starting into free growth, and must be encouraged. Manure-water will suit them well, and if in lean-to houses, put them on shelves next the wall where there would be too much light and heat for almost anything else.

Stove and Orchid House.

ACHIMENES, GLOXINIAS, AND GESNERAS will rejoice in a moist atmosphere with a generous temperature. They must have some shade, but Gesneras will stand the full sun the best. Train out betimes, and give air to keep the growth robust.

STOVE.—Sprinkle water frequently upon the pavement, to keep up a moist atmosphere, especially where Begonias and other soft-leaved plants are growing. A single drop of water on the leaf of any of the variegated Begonias will spoil its beauty, but they will absorb atmospheric moisture to almost any extent if the temperature suits them. Give orchids plenty of water, and wherever sunshine can be admitted without positive harm, give it a welcome as a positive good. Propagate *Clerodendrons*, *Erythras*, *Poinsettias*, *Euphorbias*, &c.

BEGONIAS of all kinds need repotting if not already attended to. This is a good time to propagate by pieces of the rhizome or by leaves. The soil should consist in great part of leaf-mould, with a little good loam and turfy peat. Shade, moist atmosphere, and no water on the leaves.

GARDENIAS done blooming require a thorough good moist heat; if over fermenting material, all the better. To be dry or cold will cause them to be eaten up by vermin.

Forcing Pit.

FORCED FRUITS.—Give air freely to these, or they will lack flavour and colour. Houses in which fruits are forced should have the lights merely screwed on, so as to allow of their removal altogether when the weather permits, which it will now, and to the advantage of the crop, especially of peaches and cherries. Avoid that bad but common practice of laying in an abundance of wood, for instead of furnishing plenty to choose from at the winter pruning, it is more likely to furnish none at all, for the crowding of walls and trellises renders all alike soft and sappy. Lay in wood as required, and thin away all other growths, and you will get wood worth keeping, instead of a forest of mere spray.

PINES.—Many fruiting plants are now advancing, and require good treatment. Where there is no fruiting house, the fruiting plants should be placed where they can have plenty of air, as that is indispensable. Succession plants must be encouraged to grow, and should have as much light and air as can be reasonably allowed them. To keep them close and over-much shaded at this time of year will be seriously injurious.

STRAWBERRIES have been ripening fast and fine during the past three weeks, but their wants have been of a most prodigal kind. Where they have not wanted for air or water, they have coloured superbly. When the fruit is all off, carefully harden the plants before exposing them fully to the weather. If pressed for room, some of the stock may now be put in pits to ripen off.

MELONS in fruit to have less water as soon as the fruit begins to ripen. Let them have the full sun, no matter how it may roast them; shut up early with a good heat, and sprinkle the leaves at the same time. Those

lately planted out to have soil added to the hills as required, and linings if the heat declines. Do not allow fruit to swell until you have a good plant.

Figs.—In early houses there is much fruit ripening now, and the syringe must be used with caution. But it must not be dispensed with altogether, because of the liability to red spider. Care must be taken therefore, especially as, though there may be much nearly ripe fruit in the house, there will also be much immature fruit needing assistance.

PINES to be shaded as little as possible, except those lately potted. Give plenty of air and plenty of water. Keep a brisk heat to succession plants.

CUCUMBERS in frames must have water regularly, and especially before shutting up, to promote a humid atmosphere. It will be probably found, by thrusting in the hand next the sides of the frames, that the soil is quite dry a few inches from the surface, and that wood-lice are ensconced there very comfortably rolled up hard and globular like pills. Mero water is a great discomfort to these gentry, but boiling hot water poured all round next the wood will kill them wholesale.

VINES to be stopped and the bunches thinned in good time. Set by hand Muscats, Wes's St. Peter's, Golden Hamburg, and others that are shy of setting. The Muscats will require a brisk dry heat while in bloom. See that all vines are sufficiently moist at the root, and those swelling fruits to be regularly syringed. Look to the stock of young vines for fruiting in pots; give them liberal culture. Where crops are ripening, raise the temperature to a maximum of 90°, with a minimum of 65°. Muscats are worth nothing in a low temperature. Stop laterals, remove superfluous shoots, and on all the wood left, whether young wood or bearing shoots, let every leaf remain. The removal of leaves to admit light to the bunches is almost as bad as putting the bunches in an oven to ripen them.

CHERRIES require to be thinned, and must have plenty of water. Temperature 65° to 75° day, 47° to 55° night.

PEACHES AND NECTARINES to be liberally supplied with water, plenty of air, and full sun. Strong shoots to be pinched in; useful shoots to be tied in. Keep a watchful eye as to the furnishing of the lower parts of the trees; if they are allowed to make gross shoots high up, they will get bare at bottom, and it is always a sign of a careless or unskilful cultivator when the trees are irregularly furnished.

Literature.

STEINMETZ ON THE PHILOSOPHY OF THE WEATHER.

Sunshine and Showers: their Influences throughout Creation. A Compendium of Popular Meteorology. By ANDREW STEINMETZ, Esq., of the Inner Temple, Barrister-at-Law. Reeves and Co., Henrietta Street, Covent Garden. 432 pp.—A clever book on the weather is about as good a thing in the way of literary work as can be offered to the British public, for though our libraries are well supplied with what are called "standard works" on meteorology, there are but few really useful hooks adapted for the masses of the people. To a certain class of minds mere figures are as poetry; the multitude, however (and the multitude are not fools, be it remembered), care little about figures and only look for results—that is to say, for orders of sequence, for laws, for coincidences, for whatever in the concrete can be extracted from figures by the application of those who love them for their own sake. Take, for instance, the elaborate meteorological returns from the Kew Observatory which are periodically published in the *Intellectual Observer*, and of what use are they to any promiscuously gathered thousand enlightened citizens? There may indeed be one in that thousand who is anxious to know what was the range of barometric pressure and of temperature, and the total of the rain-fall in January last; but the remaining 999 want to know—that is if they are curious at all on meteorological subjects—they want to know what sort of weather we shall have to-morrow, or on Wednesday next, or a week hence, or a month hence—ay, for any time to come, but as for the past, they are prepared to say, "Let the dead bury their dead." Now this is common sense, let the pseudo-philosophers say what they please. It is simply an application to meteorology of the rule that is found good in other departments of physics, aye, and in morals and mental philosophy too. It is a judging of the tree by its fruits. We conclude that if a theory is sound its application will be useful to mankind. If great expense and much talent are expended on the registration of meteorological phenomena, we ought to have as the result some better guidance than guess-work as to the weather of the future. What is the use of all these instruments, these tables, these nice distinctions, if they do not lead to a means of forecasting with some degree of accuracy the state of the weather for some hours or days in advance of events? We are not prepared to say that, in the absence of improved means of forecasting, these instruments and tables are of no use, but we do say without hesitation, that if they do not point to the future with some degree of certainty, the public will have no faith in them, and meteorology must rank with archæology, as a science of the past and not of the future, and hence will have but few followers. Happily all the labours of meteorologists tend towards the happy consummation, the power of predicting what the next weather will be. The book before us has been written, by one peculiarly gifted for the task, with the view of enabling every thoughtful and observant man to be his own weather prophet; a far more desirable end than the constitution of schools of weather prophecy, because what a man foresees for himself he will provide against, but what, as a rule, is indicated for him, however correctly, he will scarcely heed, and therefore will not benefit by.

It is with peculiar pleasure we introduce this book to our readers. It is able, it is crammed full of practical wisdom; it is more than it professes to be, for it furnishes a complete key to the laws of meteorological vicissitude, and moreover it is written in a most plain, homely, simple style, and affords an agreeable illustration of the ease with which a master of a difficult subject may, if he chooses to put aside pedantry, make that subject understood by the common people, such as we reckon ourselves and (we beg their pardon) our readers to be. Perhaps at this point some readers may raise the question of the possibility of forecasting, and so beg the whole question in a negative way, with the view of ignoring the book. Well, we do not mind illustrating this point by the statement of a fact. An experimental horticulturist, who considers himself somewhat of a judge of the weather, had in hand some important undertaking requiring a considerable amount of out-door work. Long since, foreseeing bad weather throughout March, he put on extra force and got all done before February

was out, though in ordinary seasons the work might have been carried on throughout the whole of the past month. The reader need not know what the particular work consisted of. Let it be draining, planting, or even the sowing of seed, it is clear that a whole month has been gained by the exercise of judgment, and the acting upon conclusions as to the coming weather. Suppose that in the case before us, the particulars of which we withhold for proper reasons, the work had been allowed to take its usual course, it is evident that several weeks must have elapsed between the 23rd of February, when the last stroke was finished, and the resumption of labours; and what are several weeks worth at this time of year? We leave the question to practical men, and pass on to the book before us.

The object of the author is to render a subject which is truly complicated so plain that he who runs may read. He has not quite succeeded, but he has done wonders towards popularizing without degrading meteorological science. He acts out by supposing the reader knows nothing about it, and that is the proper way in any book intended to popularize a difficult subject. He presents sketches of the known laws and phenomena of the atmosphere, and then proceeds to describe the instruments by means of which the conditions of the atmosphere are ascertained, irrespective of our own feelings, which are always deceptive. Then follow applications of the facts observed, and the laws deduced, to the great subject of weather prognostication, and it is pretty certain that the reader who will make a study of this book will in the end become well fitted to "forecast the weather," in so far as the art of doing so is possible in the present state of our knowledge. We are bound, above all things, to notice in this work the agreeable, communicative, almost anecdotal tone in which it is written; it reminds us sometimes of the fascinating style of Sir John Herschel, who amongst modern philosophers is pre-eminently happy in popular elucidations of the principles of physical science. In exemplification of our eulogy, we have made a few extracts, and these we submit, without any attempt to connect them together, for they relate to specific subjects, and have a value of their own apart altogether from these remarks on the general scope and purpose of the book.

DRAINING AT DEPTHS OF TWENTY AND THIRTY INCHES.

"At these depths the great advantage of draining becomes strikingly evident. During the prevalence of frosty weather in February for three weeks, the mean temperature of the drained land at 20 inches was 35·2°, and the undrained 34·7°. Hence the effect of drainage at the lower depth was to keep the soil 1·3° warmer during a protracted frost—an immense benefit to vegetation. Moreover, whilst at ten inches the rain raised the temperature of the undrained more than that of the drained land, it is just the reverse at 20 inches, at which the drained land had the advantage. It was the same with snow, the effect of which was to prove that the cold resulting from a covering of snow is more quickly transmitted through undrained than through drained land.

The mean annual temperature at each of the three depths was greater on the drained than on the undrained land, the amount being at 10 inches 0·8°, and at 30 inches 0·7°. The annual mean temperature at nine a.m. is greater at 20 inches than at 10 or 30 inches; from which we may infer that the daily wave of maximum temperature has at nine in the morning passed 10 inches, and penetrated to about 20 inches, but has not yet arrived at a depth of 30 inches. Hourly observations of the underground thermometers, conducted from time to time under different states of the weather, would be of great service in determining the march of the daily wave of temperature through different soils. Since changes of temperature are more readily transmitted through undrained than through drained land, it follows, from the small excess of the drained land at 20 inches, that at nine a.m. the daily maximum had penetrated to about 20 inches in the undrained land, but that in the drained land it was still some distance from that depth.

The difference between the temperature of drained and undrained land varied greatly in different months and at different depths. At 10 inches the excess is much greater during the warm months, from May to October, being 1·1° as compared with 0·4° during the other six months. But at 20 and 30 inches the greatest excess occurs during the cold half of the year, from October to March, being at 30 inches 0·9° as compared with 0·4° during the summer months; and at 20 inches 0·6° as compared with 0·2°. It may be remarked that when the excess is greatest at 10 inches, and least at 30 inches, the heat is increasing from the surface downwards; but when the excess is least at 10 inches, and greatest at 30 inches, the upper layers being coldest, heat is passing from below upwards.

The temperature at 10 inches reached the maximum on the 25th of July, and fell to the minimum about the 21st of February, and the mean temperature occurred about the 21st of March and 21st of October. At 30 inches those periods fell from one to two days later, except in April. Then it occurred four days later, owing to the rapidity with which the temperature rose to the mean in that month, longer time being required to raise the temperature of the lower depths.

The coldest month was January, 34·2°, and the warmest July, 58·8°. In the drained land the coldest winter and the warmest summer temperatures at the different depths were respectively 34·0° and 59·9°, 35·4° and 59·1°; and 36·0° and 57·4°; and in the undrained land 33·9° and 58·9°; 35·1° and 59·2°; and 35·0° and 57·0°.

Thus the difference between the mean temperature of the coldest months was, in the air, 24·6°, in the drained land, 25·9°, 23·7°, and 21·4°, and in the undrained land 25·0°, 24·1°, and 21·9°, and hence the annual fluctuation of the mean monthly temperature was greater at 10 inches, about equal at 20 inches, and less at 30 inches, than that of the air.

USES OF THE HYGROMETER.

It is in conservatories that the hygrometer is indispensable. How often do our greenhouse plants become shrivelled or weak before we have the least suspicion that there is any alteration in the humidity of the air! Then, as soon as we become alive to the fact, we drench them with water, without taking their actual requirements into consideration. On the other hand, if we fancy, from our own sensations, that the air of the conservatory is too dry, we sprinkle water about without measure. But, as Mr. Glaisher observes, our sensations with regard to heat and humidity are very fallacious guides. Everyone must have felt in summer the heat to be at times almost insupportable, without any apparent reason, as shown by the reading of the thermometer. This happens when the air is nearly calm and moist; the air is already so moist that it cannot take off our own moisture as we give it off in perspiration, and so we say it is "sultry;" but only let the air get in motion, even only by means of the Indian punkah

or huge fan swinging about, and then we feel cool and experience relief. Yet the same hygrometric conditions exist. It is only a very small amount of vapour and heat that we force the air to take from us by the process. But should the air get drier with the same temperature, then evaporation from the skin takes place with great activity, and we feel a marked sensation of cold; and this result is as great a fallacy as the former. The fact is, that with the same temperature, and enjoying an equal state of health, we experience, according to our mere sensations, various changes of temperature, and so our senses cannot guide us with regard to heat and humidity, as far as our own health is concerned, and much less with regard to our plants. Therefore the hygrometer, properly used, and its indications attended to, may be made the means of preserving many valuable plants which might otherwise perish in an ill-regulated atmosphere.

We presume that most of the superior gardeners are acquainted with the nature of the proper climates of their plants. At any rate, such knowledge is necessary for their proper treatment, not only as to temperature, but also as to moisture. With this information they can easily regulate the atmospheric condition of their conservatory. For example, suppose the temperature of the climate of the plants be 70°, and its mean state of humidity about 60 or 70 per cent. of the quantity of aqueous vapour which the air would contain if saturated, as before explained. Then, by consulting Mr. Glaisher's tables, we find that in order to secure this climate for the plants the reading of the dry-bulb thermometer must be 70°, and the reading of the wet-bulb thermometer between 60° and 64°. In this manner we can match any climate under the sun, as Mr. Glaisher's tables, which should always accompany every hygrometer, include every temperature and degree of humidity. We have only to look out for the temperature of the dry-bulb in the first, and find in the eleventh column the degree of humidity required, and then, in a line with it, in the second column, we shall find the requisite reading of the wet-bulb to secure it.

Having made this discovery, all we have to do is to introduce a large surface of water, with a moveable cover, to regulate at pleasure the extent of evaporating surface, and then we shall have the means of obtaining and securing continually the requisite degree of humidity.

AIR-HEAT AND EARTH-HEAT.

The temperature at the surface of our globe is, from a variety of causes, such as we have mentioned, liable to great and sudden fluctuations; but this is not the case as we get below the surface. The lower we descend the smaller the fluctuations become, until at length we get to the stratum, or layer of *invariable* temperature, which varies in different soils from 50 to 100 feet below the surface.

We have before us a table showing the mean monthly temperature at various depths and in the air at Greenwich, from an average of thirteen years; and it appears from this table that the full effect of the solar heat received by the earth in the summer months does not reach to the depth of twenty-four feet until about the end of November or beginning of December; and that the lowest temperature is not attained till June, by which time the absorbed heat has been radiated, and the ground has received a fresh supply. The following are the dates of the middle of the warm and cold periods for six thermometers, from an average of thirteen years, at the Royal Observatory, Greenwich:—

Thermometers.	Middle of warm period.	Middle of cold period.
1. Air	July 21	January 20
2. 1 inch underground	" 26	" 24
3. 3 feet	August 9	February 8
4. 6 "	" 25	" 24
5. 12 "	September 25	March 27
6. 24 "	November 30	June 1

From this table we see that the thermometer, whose bulb is only covered with an inch of soil reaches its highest and lowest readings at dates differing only a day or two from highest and lowest, as marked by the thermometer free in the air. The three-feet thermometer is about nineteen or twenty days behind the instrument in the air; that six feet below the surface is retarded by still more; and this goes on increasing with the depth, until at twenty-four feet the times of maxima and minima are retarded between four and five months.

The range of the mean monthly temperature at the different depths is as follows:—

Thermometer in the air	29.8 degrees
" sunk 1 inch	25.4 "
" " 3 feet	21.7 "
" " 6 "	15.4 "
" " 12 "	9.5 "
" " 24 "	3.4 "

As before observed, the geological peculiarities of the soil in which the thermometers are sunk will make some difference in their readings, some strata or layers of the soil having a much greater power of conducting heat than others. It takes about five or six days for the impression of heat to penetrate through one foot of earth, subject to slight variations in different soils.

From these facts the reader will perceive how much warmer the roots of plants are during the winter than the portions that remain above the ground; and the contrast becomes more striking when the winter is very cold. When we are hardly able with the greatest care to keep life in some of the plants above, those beneath are luxuriating in a temperature many degrees warmer, provided they have fair play, and are not over supplied with moisture, the excess of which makes lands "cold" and ungenial to vegetation. Thus we can understand why the natives of the ice-bound regions of the north retire, when their short summer is over, to homes below the surface of the frozen ground to pass the long winter.

The practical application of these facts and principles should be easy enough. Having, by means of your ground thermometer, discovered the maximum, or middle of the warm period of your land, the further it is from the maximum, or middle of the warm period in the air, the greater the certainty that your land is in good condition of heat and that the cold period will be delayed, so as to counteract the effects of a cold untoward spring.

The effect of good drainage in thus getting the land into good heat, that is to say, in point of fact, increasing its capacity for absorbing heat, has been generally admitted; but we are tardy as yet in seeing the immense advantage in the same line that is likely to result from *deeper subsoil cultivation*. If anything will tend effectually to counteract the stress of untoward seasons, it is, we believe, deeper cultivation, of which nature gives

us a hint in the length to which the tiniest roots will delve below the surface, seeking better conditions of life and growth. In proof of this, we have only to refer to cultivation in Japan, one of the wettest of countries, but with an *arable* soil of some twenty feet deep, instead of only six or eight inches as in England, and consequently incapable of suffering either from drought or excessive rain-fall, and producing not only enough for her own population—at least equal to ours—but also for exportation; and more than that, for *any* cultivation—at will even *rice*, which requires flooding."

Correspondence.

A FACT ABOUT SARRACENIA GROWING.—Mr. Editor, I think I can add a fact to Mr. Prosper's pleasant paper on *Sarracenia*. After all that has been written, and all that has been seen, can any London nurseryman or plant-grower really grow quickly and naturally even the commonest kind, *S. purpurea*? True, they grow them by keeping them moist with a syringe, and all sorts of troublesome nonsense, as if one were trying to fruit the Mangosteen or grow the *Rafflesia*; but do they propagate and cultivate them rapidly, as one would expect "good cultivators" to do with a bog-plant of North America? Nothing of the kind! How many hundreds of times have fine batches of *Sarracenia purpurea*, the kind which your readers can obtain and accommodate most easily, been introduced to English nurseries and gardens in quantity, to receive a little coddling attention, and to perish after a few months! Who among London nurserymen increase this plant so that they have what we usually call a stock of it? The fact is, they cannot, for they do not grow it as it ought to be grown, though they take infinite pains with these most curious pitcher plants. The way to grow *Sarracenia purpurea* is this: get healthy, fresh, young plants that have not been overdone with this coddling, and in the spring of the year pot them in peat, with a few lumps of crocks or a few lumps of peat at bottom,—the last the best,—using 32 or 48 size pots, according to the size of the plants, and then place them on a light shelf in a greenhouse or pit, near the glass and full light in either case, and then place a saucer under each, filling it with water, and keeping it so; not otherwise attending to the plants, except perhaps to syringe them when the other inmates of the house or pit receive that attention. In that way you will have dwarf, healthy, and stubby specimens of this most interesting plant that will bear comparison with any in existence after a year or two's growth. And bear in mind that even at Kew, and many famous gardens, you rarely or never see a thoroughly free-growing "home-grown" *Sarracenia*, while every amateur may have it by pursuing the course above named. SIMPLICITY.

Replies to Queries.

Arabis lucida variegata.—G. M.—In replying to "Variegated Alpine," we quite overlooked the fact that Messrs. Stuart and Mein, of Kelso, N.B. have been advertising this charming edging plant for some time past in the pages of the Magazine. G. M. and others will now know where to send for it.

Ferns.—North of Scotland.—*Leptopteris superba*, otherwise called *Todea superba*, thrives in a warm greenhouse, and probably would do well in a cold greenhouse. The principal point in its cultivation is to keep it in a close damp atmosphere, and, in fact, to treat it as the filmy ferns are treated. It is usually kept covered with a bell-glass, but a case would do better still. If taken good care of it never need be ventilated at all, but if made too wet a little air will be necessary, and the safest course would be to tilt the bell-glass slightly. The soil should be good peat two parts, and silver-sand and broken stone one part. The other fern you inquire about is called *Asplenium nidus*, otherwise *Neottopteris nidus*. It is a noble fern of most robust habit. To grow it well, it should be potted in lumpy peat, and kept in a shady part of a damp stove; but it will do very well in a warm greenhouse, and when young is an excellent case-fern. Neither of these ferns should be kept in a house facing south, unless special means are adopted to shade them.

Peas planted deep.—"I planted peas and beans deep; my neighbours planted more shallow, and by so doing have got the start of me. Would it be wise to use liquid manure in the hope of overtaking them?"—*A. Sergeant*.—We do not approve of the use of liquid manure to such things as peas and beans; but if you have a good supply, and can spare the labour necessary, it may be used with a view to augment the weight of the crop, but it will not enable you to gather any sooner than you will do by omitting the use of it.

Calceolarias.—J. Gregory.—You had best plant out your *calceolarias* at once; they will do far better than keeping them in pots.

Amaryllis.—Paignton.—Probably the soil is not good; shake it out, re-pot it in a sweet compost, and in as small a pot as possible, and place it on a bottom heat of 70°. This may give it a good start.

Strelitzia Regina.—East Cliff.—This is the proper season for the plant to flower; and as it will not flower unless properly treated, your treatment cannot be far wrong. We prefer to grow this fine plant in good turfy loam without any peat, in a good stove temperature; it is quite useless to attempt to succeed by cool treatment, and in the growing season the plant requires an abundance of water.

Maréchal Niel Rose.—S. C.—If you wish for plants on their own roots, wait till the beginning of July, and then make a few cuttings of young shoots three inches long; put these cuttings into a pot filled with a mixture of mellow loam two parts, and sand one part; put the pot in a shady part of the greenhouse or in a frame, and put a bell-glass over; make the soil in the pot moderately moist, and take off the bell-glass daily, and lightly sprinkle the leaves. Be careful not to make the cuttings very wet. They will be rooted in about three weeks.

Calceolarias.—B. B.—On your hot soil it would be well to enrich the beds for these with an abundance of rotten manure. *Calceolarias* will grow finely and flower freely in a bed consisting of rotten manure alone, and this when plants of the same kinds in beds not manured, and in the same garden, are dying wholesale.

Geraniums Diseased.—J. W. E.—Your plants have been too damp and cold during the winter, and they are now in a bad state. It is common to see in damp houses some examples like yours, but rarely so bad. The only cure is sunshine. Should the sun ever again shine for a fortnight right off, your plants will quite recover. In the mean time it would be well to examine their roots, and see that the drainage is all right.

The Gardener's Magazine.

SATURDAY, MAY 11, 1867.

SALADS AND EARLY VEGETABLES ARE NOW IN GREAT REQUEST but not in great plenty. Families residing in London in "the season" generally receive at least a part of their supply of the above from their country seats, and probably a part from their greengrocer in town; others, who remain in the country, read of these things at so much per dozen bunches, or per punnet, at Covent Garden Market, long before their own gardens will afford them in any quantity, if at all; and country gardeners are doubtless often asked by employers why the London market is supplied so much earlier than themselves. Gardeners who know both town and country can easily answer such queries; but all the world of horticulturists have not the advantage of such extensive experience, therefore we have been induced to offer the following remarks, not because we admire the high prices at which they are sold, but because of the earliness and generally delicate quality of the vegetables and salads now to be seen in the first-class greengrocers' shops. The difference alluded to arises from two causes: the market gardens about London and other large towns are so sheltered by buildings, or the peculiar formation of the country, that they feel next to nothing of the sweeping easterly blasts that are experienced in the country; but more, perhaps, depends upon the nature of the soil, that near London having been for many years under the special culture of the market gardener, and it has, from the great supply of manure available, become light, porous, and rich; and from its consequent dark colour is calculated to absorb the utmost amount of warmth from the sun's rays, and, in fact, it possesses all the conditions calculated to promote rapid and luxuriant growth; whereas in the country, the avidity of stewards for all or the greater part of the manure that is made, and the supineness of masters in placing at the gardener's command the necessary means, make it difficult for him to compete, either in point of earliness or quality, with the market gardener. He has to contend as well with the crotchets and jealousies of stewards and gamekeepers. If he wants manure, the steward cannot spare it; if he wants soils, there are no horses available for carrying it; if he wants leaf-soil, the gamekeeper cannot have the "covers" disturbed; and if he wants bone-dust, guano, &c., the master cannot see the necessity for it. We must tell such they cannot reasonably expect the produce unless they furnish the necessary means.

Having so far prepared the way, we will now offer a few remarks on the various substances and means suitable for improving and forwarding early crops, where such are not at present satisfactory, some of which may be procured in most localities. Those who have light and porous soils have only to thoroughly enrich and protect them. The first may be accomplished by liberal dressings of bone-dust or artificial manures, and a thorough pulverization by frequent digging, hoeing, &c. Protection, to a considerable extent, may be secured by placing lines of common wattled sheep-hurdles at frequent intervals amongst the crops; or more permanent fences of reeds, or feather-edged boards, about three or four feet in height, and if tarred with coal-tar once a year, they would last a long time. Those who have stiff or harsh soils have much more to do, as they have not only to thoroughly enrich and protect them, but to reduce their texture mechanically. This requires much labour, as well as a most liberal introduction of friable substances—leaf-mould where old woods abound, or peat-earth, scorings from ditches and all kinds of vegetable refuse, charred rubbish and burnt earth, road-scrappings, and sand. Any of these should be secured, and be put in a heap with a moderate admixture of fresh lime to kill insects, and reduce the texture of the mass. This, after frequent turnings, should receive a liberal allowance of bone-dust, or night-soil, farm-yard dung, &c.; but it is of little or no use applying any of them to the soil in their crude state, therefore let them be thoroughly decomposed, and then added to the particular spot, if ever so small, in sufficient quantity to be appreciated. Thus a border, or one "quarter" of the garden at least may be rendered

fit for the production of early crops. But we do not advise such an extensive use of these ingredients upon the main part of the garden where summer and autumn crops are to be grown, as a greater degree of substance in the soil is necessary for these.

CLOTH-OF-GOLD AND COLEUS VERSCHAFFELTI.

When I take into consideration the number of beautiful effects in bedding it was my good fortune to see last year, I am somewhat puzzled to determine which was the best, taken as a whole; for amongst those of our professional men who are called upon from their position to exercise great taste and skill in the arrangement of colours, the race for the premiership was so nearly balanced that I cannot say who should bear the palm. But it would not be so if I were asked for an opinion upon the best two bedding plants, which I saw as worthy competitors, to make an effect, either in a well-arranged parterre, or for a separate bed where there was no special design; for I should without any hesitation say, "If you have a pet or choice bed that you wish to fill with beautiful subjects, then choose the *Coleus Verschaffelti* for a centre, and a double row of the *Cloth-of-Gold Geranium* as an edging."

But as I must be truthful in this case, as I have ever been, I must tell the reader how I came to alight on this subject at so opportune a time. I was digging out some stray notes from my pocket-book which I made use of last year in my tour of inspection of some beautiful gardens, when my eye rested on the following short paragraph in connection with this subject: "Saw at Lord Rokeby's, Hazlewood, near Watford, Herts, the finest effect of *Geranium Cloth-of-Gold* as an edging, and *Coleus*, named above, as a centre of a circular bed, that I have seen this season." I had no sooner run my eye down these notes than a very vivid recollection came across me of the condition of these plants at the time I saw them; and a sense of honour compels me to remark that I ill requited a friend for the kindness shown me by the then able gardener at Hazlewood, who, although busily engaged with Lady Rokeby in arranging the planting of some sub-tropical plants, found time to show me all there was to be seen, as likely to interest any one connected with a garden; but a press of time, and other equally interesting subjects, prevented me from noticing the many curious and good things I saw there, and which must be my excuse for not making use of the notes I then collected. To return to the heading of this short paper, I may remark that in the whole course of my experience I never saw the *Cloth-of-Gold Geranium* done so well as it was in that neighbourhood. In fact, I believe it is not properly understood by many, for here it was, in conjunction with the *Coleus*, favoured with the richest soil that could be got, and it certainly well repaid the cultivator for his pains; for at the beginning of July it was making a growth equal to the strength of a *Christine geranium*. And it is worthy of remark, that in other adjacent places—at Langleybury (the grove) and at Casisobury—all in the same neighbourhood, it was equally as vigorous. But in no other country did I find it in such good condition, thus showing that either Hertfordshire is peculiarly adapted for it, or it is not properly understood by other cultivators; for while here it grows with the vigour of a *Christine*, we generally see it but little better than the *Golden Chain* in growth. Those who have not seen it so arranged and so liberally cultivated, cannot form a correct opinion of its merits, more especially when backed up by the *Coleus* above named; for while the one is dark and sombre, the other is cheerful and light; and when combined in a circular bed, the soft tones of the gold bands upon the leaves of the geranium light up and blend with the peculiar colour of the *Coleus* in such a manner as to make the effect at once pleasing and refined.

J. C. CLARKE.

ON EARTHING THE ROOTS OF GROWING CROPS.

The term "earthing," or "moulding up," is understood by gardeners to apply to the practice of giving additional supplies of fresh earth to the roots of growing crops; and it is to the utility of the practice that I wish here to devote some space, with a view to assist those to appreciate and understand it whose experience in such matters of detail is limited.

In the first place, I may safely say it is a part of the details of the labour of a kitchen garden that many neither appreciate nor understand. They do not appreciate what other people recommend as essential for the well-being of any particular crop, simply because the idea did not originate with themselves, and they cannot bring

their minds to accept it as useful, while they see their crops producing moderate results without it. They are content with their old notions, and thereby continue to ignore by their action what others have proved an immense benefit to many growing crops, and which would do them equal service if the same practice were worked out on a liberal scale. As to their understanding the value of such simple details, it is not to be expected that the crude state of their minds will allow them to do so; therefore they must be allowed to wait their own time, or until the force of circumstances brings it clearly home to them, before they can be expected to receive the suggestions of those whose only interest is to assist them to understand the essential details upon which depends much of the labour of a garden.

For myself, I cannot imagine anything more disheartening to a public writer than to find, after he has been at the pains of detailing any particular method of culture of some favourite crop, that the public have taken up some of the main features of the plan, but have neglected altogether some of the details, and then wonder why they are not so successful as the author of the plan has been; yet such is a common occurrence, and a good method of cultivation, when properly carried out, is often thrown up in disgust simply because people neglect those details which the author of the plan found essential to success. It is so with earthing or moulding, for there are few crops of the kitchen garden but what are immensely benefited by it; but how often do we see a proper system of earthing carried out? It is only understood and valued by those men who make their business a study, and who are ever ready to adopt those measures that are most conducive to success, let them be suggested by who they may. The reader may probably remember that, some two or three years ago, I offered a suggestion in these pages in favour of the discontinuance of earthing early potatoes, for which some kind correspondent was good enough to say I must have made such a suggestion with a view to be singular. But it was for nothing of the kind, as I simply stated what my practice led me to believe was an excellent plan, and which I have since continued to adopt with increased success, and which many far better and more skilful men than myself are constantly recommending. I have merely mentioned this circumstance to show how narrow-minded some men are, and how little value they set upon the efforts of others when trying to make known something that does not exactly fit their own stand-still principles.

The value of earthing all growing crops is only to be measured by the subjects under cultivation, and the purposes for which they are required—as, for instance, the value of repeated applications of some fine dry earth, gently shook over small seedling plants at this time of year, such as the seed-beds of all the Brassica tribe, can never be estimated at its correct value except by those who have worked it out in previous years, as very few will credit the stout, sturdy plants it creates, to say nothing of the increasing number of young rootlets that are formed by encouraging young roots to spring forth higher up the stem. This is more especially valuable in stiff clayey soils, where the young plants have nothing beneath them to induce a downward tendency of the roots. These remarks apply with equal force to the same plants when removed to other quarters. Spring-planted cauliflowers, for instance, are greatly benefited by the addition of some fresh soil drawn up to their roots two or three times during their active season of growth. The same may be said of the autumn and spring planted cabbages, and, indeed, any of that class that is supported by a stem only a few inches high; for, besides encouraging a greater root action, the additional supply of earth serves to steady them against the wind, and prevents that rocking, if I may so express myself, that all such plants are subject to if there is not sufficient weight against the stem to keep it firm in its proper place. Peas, again, are greatly benefited by constant earthing, as it serves during dry weather to prevent that excessive amount of evaporation that would otherwise take place. All kinds of beans will keep in bearing longer if they receive two or three fresh earthings during the season of growth; but the most successful of all the crops I have yet dealt with was the custard vegetable marrow. This delights in fresh soil, and, in fact, with me does much the best when about every three feet of the stem is layered as it were, and a basket or two of earth placed upon the joint. Cucumbers, too, are strengthened in this way, especially when they have been in bearing some time; and it is well known that when melons are grown in ordinary frame beds the young fruit swells much faster when the fruiting shoot is covered with earth than when exposed to the heat of the direct action of the sun. And, while I think of it, if I may go into the flower garden for a moment, stocks and asters are especially improved if the stems are earthed up once a fortnight while they are making their growth; so also are all the border annuals, if previously thinned out, and about two sprinklings of fine earth shook round their roots; it will do them more good than four times watering would do.

Turning again to the kitchen garden, we find tomatoes do much better when earthed once or twice, or, what is better, about two

applications of fat dung laid round the roots. In early spring old strawberry beds, when the crowns have risen above the level of the soil, receive quite a fresh stimulus if some rich fine soil is laid round the roots; into this they make vigorous roots, as it is more kindly than an ordinary border soil; and the same may be said of seakale and rhubarb plantations. Many fail with radishes, when grown under glass in early spring, because they will not take the trouble to earth them, that is to say, to give them a sprinkle of fine dry soil every week to cover up the stems of the young plants, which at this early season are always drawn for the want of sufficient air. In the absence of anything better, I have frequently used dry sifted cinder ashes, and for many young plants this is better than soil, as the roots will work in it quite as freely, and it prevents at the same time the slugs working amongst them, as they do not like the rough surface to travel upon.

As a last remark, I cannot avoid saying that gardeners generally do not attach sufficient importance to the practice of earthing all young seedling plants, as it is a sure preventive against their getting long-legged, as well as against mildew and, that worst of all evils, damping off—at least, such is the experience of an

ENGLISHMAN.

RAISED *VERSUS* LEVEL FLOWER BEDS.

It may not be generally known amongst the country readers of the GARDENER'S MAGAZINE, that in such places as *Keu Gardens*, the *Crystal Palace*, and other large places round London, where the best displays of bedding plants are to be seen, in the majority of instances, the beds in which the plants are growing have a level surface, or rather, perhaps I ought to say, instead of sloping downwards from the centre to the outside, the slope is the reverse way, as they dip very gently from the outside to the centre. Now the advantage of this arrangement must be manifest to every one who has anything to do with any number of flower beds; for as soon as the beds require water, the labour they entail when raised far above the surrounding ground level is something serious to contemplate, if there is any extent of flower beds. But with these inclined surface beds the quantity of water required is insignificant, when compared to beds that are perched up on mounds; for where a raised bed would only be gently moistened by some half-dozen cans of water, those with the level of the surface reversed would have a good soaking from only half the quantity, and therefore would not require another supply for some days after the others. It surely cannot require any further argument to convince any one of the utility of adopting this plan, especially where labour is scarce, and where the seat of operations is distant from a supply of water; and a moment's consideration will convince any one that a raised bed is not conducive to the retention of moisture, for we all know that when water is applied to them half of it runs to waste where it is not wanted, round the sides. This is especially the case when water is not given carefully and steadily, for if any attempt is made to rush it on, so as to get over a large space in a short time, half the labour and water will go to waste; but with the form of surface I advocate the water may be given more speedily, and if only ordinary care is used every drop will be appropriated by the plants it is intended for.

I am not arguing that this form of surface is applicable to every soil, or to every class of plants used for bedding out, because, in the first place, a stiff cold soil does not need much water; but on light sandy or gravelly soils it is worthy of adoption by all those who take any interest in the well-doing of the plants in the flower garden. In the second place, there are certain plants used for flower-garden decoration whose habit and growth would not admit of such an arrangement; but these are few in comparison to those that would be benefited by greater supplies of water in hot dry summers, such as that we experienced in 1864 and 1865, the like of which would be very acceptable, after the long and severe winter just past.

If it is not out of place here, I would just refer to the importance of trenching up deeply every flower bed and border during winter. This is the best proof against the requirements of water of any I have yet seen practised, as by encouraging the roots to go downwards they are more out of harm's way, and when they get well established with their roots taking a downward course into the fresh open soil below, they will feel but little of a month's dry weather, should it occur. And it should be remembered that all bedding plants are better without water than with it, if they are not actually in a suffering state. I know of a thorough British gardener, Mr. Page, of *Combe House*, *Croydon*, an old and particular friend of mine, who practises this deep trenching, and his beds need but little water; and but very few, if any, can equal him in the excellence of his display throughout the season.

I have just put these few notes together, thinking it was high time I did something in return for the many valuable hints I have gathered from the pages of the Magazine, and I hope they are in such a form as to be useful to some of your many readers.

PRO BONO PUBLICO.

MESSRS. E. G. HENDERSON & SON'S EXHIBITION OF EARLY TULIPS.

In accordance with time-honoured custom, Messrs. Henderson have shown what may be done with early tulips to make a display of colour throughout the months of April and May. Indeed, to speak the truth, they have, if we consider the matter artistically, shown too much. For a set of forty beds, some of them eight feet wide, filling the great ante-garden at Wellington Road, all a-buzz with tulips, is a spectacle too dazzling to be enjoyed; it excites wonder certainly, but it admirably exemplifies a doctrine frequently enforced in these pages, that mere flat colouring is really flat in spite of its gorgeousness, and altogether displeasing to an eye trained for the perception and enjoyment of beauty. We remember, of course, that we are in a nursery, and that flat colouring is here a matter of business; this, in fact, is at once the growing and the proving ground, but there can be no harm in deducing from it a lesson applicable to gardens generally, and elucidative of an important principle of garden taste. One of the eight-foot beds alone (they all measure about fifty feet in length) would be enough for any garden of moderate dimensions, especially one that has a great centre of white, with blocks of buff on either side, and fillings in of crimson, rose, and purple. Some of the groupings are eminently artistic, and if on the score of taste we say that the vast extent of colour without relief is objectionable, we wish it to be understood that for the present moment we are supposing ourselves to be in a private garden, for only on such a supposition will any criticism of this kind be fair.

The real value of this display is to be found on an inspection of its constituents. We have before us nearly all the varieties of early tulips that are in cultivation, and we may select from amongst them all that please us by their form, carriage, colour, and season of flowering. We are in a vast trial-ground, and the subjects under trial cannot evade a thorough scrutiny and canvassing of their merits. As regards the collection as a whole, the bloom has been most satisfactory this season. The flowers are large and stout, the colours are good; and although the late tropical weather has hurried many sorts to rags, the flowers have lasted longer than usual, and the collection is still worth seeing, though its splendour is waning fast. During a careful and agreeable inspection of the whole, the following varieties were selected as the best.

Sultana.—Cherry or cerise crimson, bright and good; a cheap variety.

Thomas Moor.—A finely proportioned cup, borne on a stout stiff pillar; the colour clear orange buff, sometimes deepening to light Vandyke brown. One of the best and cheapest early tulips known.

Silver Standard.—Rather long cup, white ground with flame and feather of cerise crimson; very pleasing and cheap.

Golden Prince.—Beautiful form, the colour clear gold yellow; first-rate and cheap.

Grootmeester van Malthea.—Extra large, stout and fine; white flaked with crimson. This is one of the latest, and may suit for special purposes, but it will not do for beds that are to be filled with summer heddors, because it does not flower until the beds are wanted for the next crop. For the plunging system, if kept hack, it may be particularly useful to put out with yellow alyssum, white iberis, and fancy pansies, before the first display of geraniums is ready.

Bride of Haarlem.—Very dwarf, good cup, white with flame and feather of cerise crimson; so much like Silver Standard that one of the two may be dispensed with in ordinary cases.

Viola purpurea.—A small cup, very neat and smooth; colour purplish rose or magenta; approaches very near to the colour called "Bishop's Purple." Very distinct; a fine contrast to yellow; expensive.

Royal Queen.—Very dwarf, deep crimson; fine. This was nearly over when most others were at their best; its presence, therefore, in a connected group might spoil the colouring, as it would come and go before all the rest.

Cottage Maid.—The cup unfortunately has pointed petals, otherwise this is one of the very best. The colour is white, with rich rose feather. It is rather dear.

Feu d'Anvers.—Much dwarfer than Vermilion Brilliant, but like that splendid variety in form and colour, being brightest flame vermilion. This blooms at the same time as the general collection, and is therefore a first-rate bedder, whereas Vermilion Brilliant is usually too early, but unequalled for pots.

Helianthus.—Like Tournesol, but a trifle better, and one of the very best of the double flowers.

La Belle Rosette.—Rather tall, and adapted for the inner beds of a geometric garden. The form is good; the colour light rose feather on white ground.

Queen Victoria.—The cup is short and smooth, pure white; cannot be surpassed; like a superb piece of ivory turning. It is rather cheap—say three shillings a dozen at the utmost.

Coeur Cardinal.—A superb short cup; colour scarlet.

La Plaisante.—Dwarf habit, good cup; colour crimson, with faint wash of lilac.

Brutus.—Fine form; colour orange scarlet; tolerably cheap, and in every sense first-rate.

Duc d'Autriche.—Very tall and very large; in these respects peculiar; colour scarlet, edged with yellow. Rather dear; a telling kind for a large design and bold colouring.

Woolman.—Neat and distinct; violet purple or puce; one of the nearest approaches to blue; very dear.

La Majestueuse.—Very fine; in colouring like Brutus; but double the price of that variety.

Duchesse de Parma.—Tall in growth, flower very large; colour bronze crimson bordered with orange; first-rate and cheap.

Proserpine.—As good in the bed as it is in pots, and not earlier than others; colour salmon tinted rose; an expensive variety.

Rosenkroon.—Semi-double, intense crimson; fine.

Colour de Ponceau.—A neat flower of average size, and in colouring one of the loveliest in cultivation, being superb crimson shading to lake. This is a cheap variety, and of the first order of merit.

Imperator Rubrorum.—One of the finest formed flowers in the collection; colour deep bronzy red. It is too early for ordinary bedding, but for pot-culture first-rate.

The collection of early tulips at Wellington Road comprises some thousand or so varieties, and of course there are many amongst them worthy of notice, and that cultivators will find useful besides those noticed above. Nevertheless, the foregoing twenty-four are such as more especially

took our attention by their distinctness and brilliancy, while leisurely exploring the garden; and we are bound to consider them the best for general purposes. The immense collection of hardy herbaceous plants at this nursery is more complete than ever, many valuable species and varieties having been added lately. The plants have not a prepossessing appearance, for the whole are kept in small pots, so as to be ready for planting at any time, and ready also to be packed in a small compass, and travel better than ground roots could do, however carefully handled. Though none of them show their true beauty, which is impossible under the circumstances, the manner in which they are kept reflects the highest credit on Messrs. E. G. Henderson, for they are in perfect health, and true to their several names. It is no small task to manage some three thousand species and varieties, many of them plants of the moor, the mountain, the fountain, and the starving rock; so at least I thought while conversing with Mr. Wood upon the subject, and observing that the Saxifrages alone have been collected to the extent of over one hundred species. Respecting other departments, I can only add that the house in which the tricolor geraniums are kept is a far more splendid place than the lost Alhambra, and I think I know the features of every geranium in it.

S. II.

SOUTH METROPOLITAN AURICULA SOCIETY.

The members of this society held their fifth annual exhibition on Thursday, the 25th of April, at Mr. J. Butcher's, Marlborough Arms, South Street, Camberwell. There was a good display, and an extraordinary attendance of the lovers of this much-neglected though best florists' flower of the day. It is to be hoped that in a short time they will be able to induce many amateurs round London to cultivate the old favourite. Amateurs and growers are invited to attend the society any second Tuesday evening in the month, at Mr. J. Butcher's, where lectures are delivered on the growth and method of culture of this once-popular favourite.

SEEDLINGS.—Mr. J. Butcher was awarded a first-class certificate for a green edge seedling, *Mrs. Butcher*, and a first-class certificate for a self seedling, *John Penn*; Mr. John Pink, of Gotha Cottages, Coburg Road, a first-class certificate for a green edge seedling, *Annie*; also a first-class certificate for a gray edge seedling, *Eliza*, and a second-class certificate for a white edge seedling, *Miss Oliver*.

In the class for SEEDLING ALPINES, Mr. J. Butcher took a first-class certificate for *Jane Webster*, *Lady Middleton*, and *Rifleman*; Mr. Pilcher, first-class certificate for a seedling *Alpine*, *Emma*.

PREMIER PRIZE.—Mr. J. Butcher, for Lightbody's Robert Traill, very fine.

CLASSES.—First prize, for eight plants, Mr. J. Butcher: *Green Edge*—Traill's General Neill, Traill's May Flower, Dickson's Duke of Cambridge. *Gray Edge*—Ashworth's Newton Hero, Lightbody's Robert Traill, Smith's Britannia. *White Edge*—Wyld's Bright Phœbus. *Self*—Martin's Mrs. Sturrock.

Second prize, Mr. Pink: *Green Edge*—Page's Champion, Oliver's Lovely Ann, Cocknp's Eclipse. *Gray Edge*—Svkes's Complete, Waterhouse's Conqueror of Europe, Lightbody's Alma. *White Edge*—Gairn's Model. *Self*—Martin's Mrs. Sturrock.

First prize for the best six plants, Mr. J. Butcher: *Green Edge*—Page's Duchess of Oldenburgh, Ashton's Prince of Wales. *Gray Edge*—Headley's Stapleford Hero, Barlow's Morning Star. *White Edge*—Ashworth's Regular. *Self*—Butcher's King of the Crimson.

Second prize, Mr. Pink: *Green Edge*—Oliver's Lovely Ann, Page's Defence. *Gray Edge*—Grime's Privateer, Waterhouse's Conqueror of Europe. *White Edge*—Lee's Bright Venus, Popplewell's Conqueror.

Four plants, Mr. J. Butcher: Oliver's Lovely Ann, Headley's Stapleford Hero, Ashworth's Regular, Spalding's Metropolitan.—Collection of twenty-four plants: Mr. J. Butcher.

ALPINES.—First prize for eight plants, Mr. J. Butcher; second, Mr. Pink.—First prize for six plants, Mr. Pilcher; second, Mr. J. Butcher.—Collection of Alpines, thirty-six plants, Mr. Daniels.

POLYANTHUSES.—First prize for the best eight plants, Mr. Pink; second Mr. J. Butcher.—Collection of Polyantuses, thirty-six plants, Mr. J. Butcher.

COLLECTION OF PLANTS (Cinerarias, Geraniums, &c.): First prize, Mr. Thomas Butcher; second prize, M. J. Butcher.—Specimen plant: First prize, Mr. J. Butcher.

THE FLOWERS IN HYDE PARK.

For several weeks past that portion of Hyde Park which abuts on Park Lane, and more especially on the walks which connect Stanhope Gate with Grosvenor Gate, has been delightfully gay with a display of flowers. We may most properly speak of this display as an example of *spring bedding*; for the plan of the bedding system has been followed, and in such a way as not in any manner to interfere with the summer bedding, for which this portion of the Park has become celebrated. All the plants employed in the present display were put in the places they severally occupy after the removal of the summer heddors in 1866, and they will all be removed in time for the planting of the summer season of 1867, a course of procedure long since advocated in these pages, and most admirably carried into effect by Mr. Mann, the able and enterprising gardener here. The parallel walks which skirt Park Lane are divided by a continuous slip of ground, along the centre of which extends a hedge of holly, and on each side of the hedge is a border facing the walk. This border is sometimes a grass-plot with beds, sometimes a solid mosaic of flowers enclosing beds of flowers—that is to say, flowers of comparatively quiet aspect are employed instead of grass for the surroundings of beds of hyacinths, tulips, crocuses, narcissi, and other particularly showy subjects. Everywhere this display is pleasing and satisfactory, and it suffices to show that many of the beautiful hardy herbaceous plants that have been well-nigh banished from our gardens are as well adapted to heighten the effect of the present elaborate and brilliant style of garden decoration, as they were to beautify the comparatively quiet borders of our forefathers. In that part of the border nearest to Stanhope Gate the display consists of tulips only on close shaven turf. This series of beds merits attention as probably the best display ever seen in or near London of early tulips, for the varieties comprise only such few as surpass all others in uniformity of growth and splendour of colour, with long-lasting properties; and the selection of these few is the result of many years' experiment and observation by Messrs. G. Gibbs and Co., of 25, Down Street, Piccadilly, who supplied

the whole of the bulbs for the purpose. There are ten large beds in all series; in every bed 450 bulbs, making 4,500 in all. At the time they were in perfect bloom their heights were as equal as if they had been bloomed first and planted afterwards—not a miss anywhere and not a single rogue. I confess to some surprise at the uniformity of the beds, for it is a most rare occurrence to see even one large bed without a rogue, or perhaps a sport. The greater part of the varieties planted are doubles, and their names are as follows: *Ilex rubrorum*, dark crimson, the grandest of all the double sorts, as it is bold without coarseness, and when at its best is a finely-made flower. Tournesol, red and yellow, particularly showy and good. *La Candeur*, double white, a very pure, solid, long-lasting flower, affording a delightful relief to the coloured varieties. *Yellow Prince*; this is a single yellow, and the best of all the yellows for bedding; in colour it is superb, in form equal to *Pottebakker* (perhaps a shade better), and it holds up its leaves, which *Pottebakker* cannot do. *Waterloo*, single, intense dark crimson, a superb variety, but blooming too early for this sort of work. *White Pottebakker* makes a nice bed, but its leaves lay about rather untidily, and it flowers too early to be grouped with such as *La Candeur* and *Rex rubrorum*.

The mixtures of herbaceous plants comprise many interesting and beautiful subjects, such as the true *Iberis sempervirens*, or evergreen candytuft, the most compact-growing species of this useful tribe, and the best adapted for bedding; *Lasthenia californica*, one of the best of the Californian annuals, and flowering now profusely from autumn sowing; *Saponaria calabrica*, also sown in autumn, and now splendid, with its little stai-like Christine-coloured flowers; *Limnanthes grandiflora*, sown in autumn; *Myosotis sylvestris*—not so good as it may be seen at this season in the country, but quite a gem for Hyde Park, where it is used to form a groundwork to fill in between beds of tulips and hyacinths—a pavement of better gems than turquoises; *Silene pendula* and *Silene pendula alba*, two of the loveliest plants on the face of the earth, and quite a triumph of skill to see them well done in this London garden. Bravo, Mr. Mann! The Reformers, who were in the park on Monday last, and who did not inaugurate a republic, or do ought to disgrace a good cause, had no idea that a reform of vastest import was proceeding quietly in the self-same spot, and a reform, too, that will tell directly on the future happiness of Englishman who love their country and honour truth and beauty. As a matter of course, *Arabis alpina* has been making sheets of snow here for some time past—a most cheap and common but intrinsically invaluable spring flower. So, too, the wallflowers have been blowing gaily, and the stock consists of a very dwarf, neat, iron-stained sort that we must know more about, because of its uniformity and peculiar adaptability for spring hedging. Many more good things are here, but I can only find time to mention thousands of polyanthus of all shades and characters, comprising rose, crimson, brown, black, yellow, fiery red, and even pink, with here and there amongst them, and by accident, quite a few superbly-laced varieties, good enough for show.

There is yet another garden here, on the slip of ground on the south side of Rotten Row. Here the principal furniture consists of rhododendrons, of which at least a thousand pounds' worth have been supplied by Messrs. Waterer and Godfrey, with specimen hollies and mixtures, with a few very choice trees. Probably within a few days of this date the rhododendrons will be forward in bloom; they were fast advancing, and many were showing colour when we saw them ten days ago. They will be worth a visit from any of our London readers, and this notice is in good time for all who wish to see them at their best. We shall hope to say something about them after we have seen them in bloom. For the present we feel it to be our duty to offer our best thanks to Mr. Mann for the ingenious and beautiful display of spring flowers, and to Messrs. G. Gibbs and Co., of Down-street, Piccadilly, for the admirable selection and the high quality of the bulbs which have so largely contributed to the success of the undertaking. S. H.

NORBITON HALL, KINGSTON-ON-THAMES,

THE SEAT OF W. HARDMAN, ESQ.

I shall not attempt to trace the history of this beautiful and interesting place, which doubtless would be very entertaining, but simply confine my remarks upon it to those points which more particularly bear a close relationship to the profession of which the Magazine is so able and impartial an advocate and representative. But before starting upon our tour round the gardens, it would perhaps be quite as well to observe that the writer of this notice did not go there with the intention of writing any commentary upon it, or in any way attempting a description thereof; consequently, he cannot possibly go into such minute particulars and details as if he had, and perhaps, after all, a sketch is better than a history. Norbiton Hall is situated about a mile from the town of Kingston-on-Thames, on the direct London road, and is nicely shut in from the road by a noble belt of trees, such as elms, poplars, and others of that class. Amongst the trees, and overhanging the wall, I noticed a fine large tree of the snowy *Mespilus* literally covered with bloom, and a very beautiful appearance it has. The house is reached by passing through a very handsome pair of gates in keeping with it, and I should fancy the lodge-keeper's house must have a very pretty appearance in the summer, when the climbers covering the veranda which surrounds it are in full leafage and flower. Directly in front of the house is an immense round clump of rhododendrons, which admirably serves the purpose of shutting out the conservatory and front door from those who may be curious enough to peep through the gates. The conservatory joins the house, and is a very handsome building, adding considerably to its external appearance. At the time of my visit it was gay with cinerarias, azaleas, and other flowering plants, grouped on the floor and on handsome pedestals. Amongst the other flowering plants, I observed a fine *Acacia grandis*, and two specimen *Eriostemons*, perfect in shape, and covered with flowers. Intermixed with the flowering plants, and bringing out their colours to the best advantage, were some beautiful masses of foliage. I must not forget a large standard orange-tree, and two handsome plants of *Chamærops elegans*, with foliage to the base of the stem. Subjects of this kind are well suited for the purpose, are extremely simple in culture, and thoroughly deserve the encomiums which your esteemed correspondent, Mr. Prosper, has bestowed upon this class of plants for conservatory decoration. After we leave the conservatory, we have to pass round an angle of the building to get on the lawn, which is on the other side of it. In so doing we pass a grand old cedar of Lebanon, fully sixty feet high, and affording a delightfully cool retreat beneath its dark and ample shadow. The lawn, immediately facing

the house, has a few specimen trees round it, the centre being reserved for croquet. We will therefore take the walk to the right, which will bring us to the farmyard, provided we follow it to its extremity. On the left of it stands a sad memento of the frost in January last, in the shape of what was previous to then one of the finest examples of *Cupressus Lambertianum*, and decidedly the best I have seen. It stands fully fifty feet high, and was faultless in shape from its base to its apex, but it is now dead. The loss of a nice-shaped plant of this handsome-growing tree of twenty feet one feels to be a great calamity, but the death of this tree be a grief indeed to those who have seen it in its beauty. A few paces after passing this tree brings us to a walk on the left, running at right angles to this one, and leading on to the plant-growing and forcing departments, which we are now going to notice; but before doing so I cannot help admiring two finely-shaped purple beeches, which overhang this walk, and when in leaf must be very beautiful, backed as they are by some immense elms, which show off their bronzy appearance to the best advantage. We will now turn down the walk, and on the slip of lawn on the right-hand side of the walk we find *Arbor-vitæ*, specimen hollies, and pines innumerable, each individual fully deserving and entitled to a separate notice, but time and space forbid. Amongst them stands a splendid example of *Thuja occidentalis*, thirty feet high and twelve feet through; a very pretty *Araucaria imbricata*, not particularly high, but capitably shaped and perfectly uninjured, which is very fortunate, when we consider the number that have been killed in the neighbourhood. To the right of this stands a fine large box-tree, twelve feet high and two feet in diameter; it has a beautiful appearance, for it is densely furnished with foliage to the ground. Amongst the many beautiful specimens of named hollies, I cannot help noticing one of the variegated kinds, which stands a little distance from the box-tree; it is upwards of twenty feet high, a telling example of what can be done by a judicious application of the knife. I must not forget a fine *Pinus cembra*, a remarkably handsome upright-growing kind, which deserves a position in all good pinetums. An immense standard rose, *Madame Plantier*, pretty clearly demonstrates that the "knife and fork" is not used in its annual prunings; it stands nine feet high; the stock on which it is worked is between four and five feet, so that it has a fair sized head; the flowers do not come up to the best kinds of later introduction in respect of shape, but it must be a magnificent spectacle to see it, as it annually is, loaded with several hundreds of its snowy flowers expanded at one time. I was sorry to see a very good plant of *Cupressus stricta* terribly injured by frost. In one of the beds here I noticed a very handsome broom grafted on a five-foot stem, and trained umbrella-shape; it has a somewhat novel effect. Farther on down this walk we come to a magnificent *Wellingtonia*, quite perfect in shape, without any irregularity to mar its outline; it stands 24 feet high, and the bottom branches must measure at least nine feet through: the shape rather than size is the chief feature, the foliage being as healthy and dense as it possibly could be. I should like every one opposed to using rotten dung in planting coniferous trees to see this specimen. After passing this point we have immense clumps of *Rhododendrons*, *Berberis aquifolium*, *Ghent Azaleas*, and other shrubs, right and left, irregularly planted, with a strip of grass on each side, varying in width proportionate to the distance of the shrubs from the walk. On the right I saw some very fine bushes of the double-flowered scarlet thorn, 15 feet high; fine Chinese *Arbor-vitæ*, from 20 to 30 feet high; and a fine specimen, fully 50 feet high, of the Sweet Gum, *Liquidambar styraciflua*. On the left-hand side of the walk I observed an immense specimen of the yellow-berried holly, worth a day's journey to see.

On the farther side of the *Rhododendrons*, to the left, the flower garden runs parallel to this walk. A broad walk runs down the centre, with large irregular-shaped beds on each side, filled with standard roses and clumps of herbaceous plants, such as *Pæonies*, *Delphiniums*, and others. By and bye the usual bedding-out plants will be planted amongst them, and which must have a very beautiful appearance, much better than if the whole were planted in masses of colour. This brings us to the houses, but before going into them we take a turn to the right, which will bring us to a portion of the grounds termed the Wilderness; but it has no right to that name, for everything about it is the picture of order and neatness. It is a grand place for sub-tropical gardening, it being so nicely shut out from the other part of the garden; and it has some fine trees and shrubs to assist in giving it a dignity and a grandeur which cannot possibly be obtained by the "bedders" alone. Fancy groups of *Pinus sabinia*, *P. macrocarpa*, and others, with clumps of variegated and plain hollies, trained and untrained, meet the eye in all directions, giving the place a charming appearance. I noted down the following in my memory as particularly good: *Ailanthus glandulosus*, quite 50 feet high, with a large head—this truly deserves the term of magnificent specimen; a fine *Cratægea crus-galli*, *Fagus asplenifolia*, *Juniperus chinensis*, *Spiræa aræfolia*, a large *Liquidambar*, a few lofty poplars, and a splendid *Cryptomeria japonica*, doing well—it is seldom one sees a plant the size of this, 30 feet high, without its having lost the lower branches, but this specimen is perfect to the ground; *Abies canadensis*, very good; and so I might go on, for I do not often see such a fine collection of well-grown trees as is to be met with here. If I have been tedious in noticing so many, I hope to be excused on the score of being partial to such things.

I shall not occupy the space in describing the position of the houses. In the early peach-house was a splendid crop of both peaches and nectarines which had quite finished the stoning process. The trees are trained up the glass, and underneath them were figs in No. 1 pots, loaded with fruit just ripening, and growing luxuriantly. In the next peach-house the trees have been planted only a couple of years, so that they do not cover the trellis yet; they are growing vigorously, and have a fine crop. On the floor a couple of dozen peach and nectarine trees in pots were loaded with fruit just stoning. These must require much labour and attention to keep the healthy appearance they present. In a span-roofed house a fine crop of grapes in pots were in the midst of colouring, principally Sweet Water and Black Hamburg. Each vine had eight or ten bunches, averaging from 1 lb. to 1½ lbs. each. In a large lean-to vinery the grapes are now stoning; the principal part of the house is covered with one vine of the Black Hamburg. Two years ago a strong rod was carried horizontally along the front, and last year young rods were carried up the roof at regular intervals in the place of the other vines. It is a rare occurrence indeed to meet with such an immense and regular crop of grapes as may be seen in this house, or such fine handsome bunches. Of course it is impossible to say accurately what the weight of the bunches will be at this stage, but judging from their size and the healthy appearance of their vines, I have no hesitation in saying that no small number of them will

weigh upwards of 4lbs. each. Amongst the other vines is a fine Muscat of Alexandria, not so early as the Black Hamburgs, but with a splendid crop of well set bunches, not a very common sight in a Black Hamburg house. An open stage immediately over the hot-water pipes was occupied with a quantity of small succession pines, and evidently quite at home. At the back were some nice young figs in pots. A pit running the whole length of the peach-houses andinery was filled with a lot of strong strawberry plants plunged in about twelve inches of tan, the sorts being Sir Charles Napier and Keen's Seedling; they were just in bloom. The borders of these houses are partly inside and partly outside, and this pit is erected upon the portion outside, and is of very excellent service in keeping the border from getting too wet and cold, and at the same time does very capably for the purpose for which it is now used. The house for fruiting pines is a span roof with walk down the centre, with pit on each side capable of holding 150 fruiterers each. It is indeed a magnificent sight to behold the 300 pines this house shelters at this moment. They are principally Queens, and every individual is a model of what a Queen pine ought to be. About half of the plants are now in fruit in the different stages of advancement, and I unhesitatingly express my opinion that this house of pines cannot be excelled in the three kingdoms. Along each side of the pathway was a row of Keen's seedling strawberry, just ripening a capital crop of large fine-coloured fruit. To supply this house there is a large pit contiguous, containing 400 good sized succession plants, which will take the place of those now occupying the house. Close to the glass round the pit I noticed another lot of strawberries swelling their fruit. Another pit was filled entirely with strawberries just set; Mr. Gray pots his strawberries firm, with the crown of the plants well up. In a small pit was a lot of Gloxinias coming into bloom, and other pits are full of thousands of the usual bedding plants. In the stove are some fine foliage and flowering plants, amongst them a pretty plant of Clerodendron Balfourii smothered with bloom. This is unquestionably one of the finest stove-plants when well done. *Meyenia erecta* is a capital thing for training on a trellis in a pit; the flowers are similar in shape to a Gloxinia, purple with a yellow throat. A fine *Stephanotis florihunda*, set with myriads of bloom. An immense *Justicia*, six feet high and four feet through, beautifully in bloom. Amongst fine-foliaged plants is a splendid *Croton variegata*; this is one of the most telling variegated plants we have for exhibition purposes. A large *Cyanophyllum magnificum*, eight feet high, grown as a standard, with an immense head, gives a very noble appearance to the house.

There is in this garden a capital collection of plants distinguished for their uses in the arts and as food; amongst them fine plants of the *Bixia orellana* or American cheese-dye, *Piper nigrum* or black pepper, the tree-cotton (*Gossypium herbaceum*), the Papaw (*Carica Papaya*), the Paper plant (*Aralia papyrifera*), and others which I cannot just now recollect. Ferns are particularly good; amongst them were fine examples of *Adiantum cuneatum*, *Blechnum Brasiliense*, and *B. corcovadense*, *Davallia bullata*, *Asplenium nidum*, the old but useful *Pteris tremula*. I have not time to notice the others which are deserving for their healthy and beautiful appearance, or the variegated *Begonias*, fine *Caladiums*, and other subjects of that class. The house was redolent with the perfume of two plants of *Burlingtonia fragrans*; one had a very fine lip, much better than the other, and the sepals tinged with rose; the best variety I have seen. They were both grown on blocks, with a little sphagnum for the roots to run in. I was curious about the number of flowers on one plant, and in counting them found no less than sixteen spikes, each spike comprising no less than fifteen flowers. I saw some very good *Stanhopeas*, *Dendrobates*, and others. In the large plant-house a very fine *Aphelaxis macrantha purpurea*, 3 feet in diameter, loaded with its beautiful blossom, deserves notice; so do some fine azaleas, ericas, pelargoniums, and a host of other plants. Will Mr. Gray oblige the readers of the MAGAZINE with a few words as to how he manages to grow *Humea elegans* 8 feet high and 10 or 12 feet in circumference, such as the two plants I saw in the camellia house, amongst a lot of healthy myrtles, orange-trees, and camellias?

In the walled-in kitchen-garden, the wall-trees are covered with fruit, and a very fine lot of pyramidal pear-trees planted round the walks are not the least interesting part of this domain. They are beautiful in shape and pictures of health. A peep into the two-hundred feet of lean-to orchard-house, where we find trees trained up the wall, presenting every appearance of an abundant crop; dwarf trees of cherries, plums, apricots, peaches, and nectarines, are planted in two rows along the front part of the house; vines at twelve feet distances up the roof; strawberries on a front shelf, and plunged at the foot of the wall; all of them give evidence that the highest skill is employed in their management. In conclusion, every piece of gravel, shrubbery, walk, and lawn, could be taken as a pattern for order and neatness, and a man of Mr. Gray's practical turn of mind would not thank me for any eulogium upon his merits, and I detest flattery. It is enough to say that everything in the place speaks for itself. A word more and then *au revoir* to Norbiton Hall. Mr. Hardman has, with the most generous feeling, placed the whole of his beautiful grounds at the disposal of the Kingston Horticultural Society, for holding their show this month. I have no doubt it will add considerably to the finances of the society, for a view of the place itself is worth double the admission fee.

G. E. G. N.

THE WATERING-POT.

The time is coming when we may expect that this useful utensil of the garden will be brought into active use; therefore "The Man with the Blue Apron" is constrained to offer a word of advice to such as may not quite understand the principles which should guide them in using it; but, as to his more learned brethren of the spade and the hoe, he is not so presumptuous as to suppose that he can infuse into their minds any fresh ideas of its utility, so he will leave them to take care of themselves, while he offers to the younger branches of the craft some advice which a long course of experience has suggested to him as essential to observe in the use of the watering-pot.

In the first place, I may remark that the bedding-out season is close upon us, as probably every interested reader well knows. Now, in this particular work, many amateurs and inexperienced people make an immense amount of work in watering that is a great portion of labour lost: as, for instance, the plants will be all placed in the bed, and the bed itself carefully dressed down, and then follows a regular deluge of water, battering down, as it is applied, the surface of the bed to an even mass of soil, rendering it impervious both to air and rain, should it occur. And this state

of things does not occur in exceptional cases, for too often we see it practised by men who would wish to be thought good gardeners, and which an old man like me would like to see discontinued, and not feel compelled, as I do now, to put it down in "black and white" before their eyes. But as I have always had the credit of being a lenient old soul, I do not wish to lose my reputation simply because I find fault with them in this instance. I am willing to admit that in some cases, when such mistakes are made, they arise from a desire to accomplish too much work in one day; as when a man has some thousands of bedding-plants to go out, it is quite natural that he should feel anxious to get them into their quarters by the most speedy plan possible; so he sets to work in right earnest, fills his beds or borders as fast as he can in one day; this done, they receive the usual coarse dressing down, and contents himself with the thought that if they have a good soaking of water the next day he will be all in good time. Now I do not mean to say that this laudable desire to get through work should be condemned, neither do I wish to undervalue the services of any man who is prompted by such worthy desires; but, as an old hand, interested in the welfare of the craft, I would ask them how it is we do not hear more about the early results of such speedy practices. It is, I fear, because they have none to relate, or they would only be too glad to show us old fogies that we are a good way in the background, and not capable of performing grand feats of planting, and at the same time secure the earliest results.

However, such have been an old man's observations during the past twenty years, although he admits that where he used to be called upon to put out hundreds, he now has to get up thousands of plants for the flower garden. For all that, the old man finds it produces grander futures to stick to his old method of planting and watering at the same time. He gets ready the position for the plant, and then only partially earths it in, when a brisk lad follows with the water-can, to which is attached a fine rose. A good soaking is given the plants, and in that condition they are allowed to remain until some hundreds of them are put out. He then goes back to the starting-point, puts more soil round the roots of the plants, and gives them the requisite amount of pressure, and then carefully removes all crocks, or any other rubbish that may remain upon the bed from the result of planting; and instead of leaving a hard and battered surface he leaves it open and porous—in fact, a surface into which both air and water can penetrate easily, to afford breath and sustenance to the roots of his plants. Besides this, by applying the water immediately to the roots, it does not require more than half the quantity to thoroughly soak them that it does when the water has to be given upon an even surface, and a depth of two or three inches of soil to penetrate at the same time before it can reach them. And he secures more than this under his plan of watering, for when the roots are well wetted, and all the soil which immediately surrounds them is covered up with a couple of inches of the dry soil of the surface of the bed, when he goes round to give the finishing stroke to them, they will endure at least a week's dry weather without experiencing a check for a want of moisture at the roots; for, he it remembered, this covering of dry soil upon the wet prevents evaporation to such an extent that the soil beneath it remains moist for some days. Whereas, if the beds are levelled down and finished off before the watering is done, it will be necessary to repeat the application at the close of every dry day; and as wise men never think of planting when the soil is very wet, it is not generally necessary to make an exception, as if the beds should be, as it is always desirable, in a moist condition at planting time, the same practice should be followed as would be when the soil was drier, as one watering so applied does more good than four times the number when given after the surface is levelled and dressed; and only think of the consolation to know, by this plan, when once your plants are finished off they are safe for the want of water for another week.

The most remarkable thing in connexion with this subject is the fact, Mr. Editor, that there are not very many who will take the trouble to ascertain for themselves the principles which should guide them in this important work of the garden, and therefore know little or nothing, whether they are doing good or harm when applying water. This is especially the case with all newly planted subjects; as we find some strenuous advocates for a repeated deluge, while others take quite an opposite course; in fact, there are some who seem to delight in seeing plants suffer for the want of water. Now the man who advocates a continual saturation of the roots of a newly planted subject, and the soil which surrounds it to such an extent that it is converted into a cold paste, can neither care to know or understand anything of the laws of Nature. They seem to know that water is essential to its recovery and existence, but nothing more; for when saturating the plants, they forget that they are unable to imbibe it on account of the absence of those necessary mouths (if I may use the expression), which have either been destroyed or injured in the process of removal, and by which they are fed and sustained. From this, then, we shall understand that as all, or rather very many, plants are injured by the course of planting, they have not the same number of organs to supply them with nourishment as a plant that is in a healthy state that have not been moved, so that it is a folly to expect that they can imbibe the same quantity of water, and which, when applied in greater quantities than can be appropriated is an injury, as it renders the soil which surrounds the roots cold and ungenial; therefore injudicious watering should be avoided, as it is likely to do more harm than good. Not that it must be inferred that water is not an essential element in assisting them to make fresh roots, because it is one of the conditions, when judiciously applied, under which alone they can be induced to make fresh roots and grow; and the man who follows a course opposite to this acts as unwisely as the other.

To make the above remarks more intelligible, I may observe that on the condition of the elements depends greatly the quantity of water required in every case; as according to the amount of evaporation going on, which is always the greatest during a brilliant sunshine, or a continuance of drying winds, the more water is required. Now, I contend if the young gardener would turn his attention to the subject of adopting all possible means of preventing evaporation, he will do more for his plants than double the labour spent on giving water to the roots—that is to say, to shade or screen all that it is at all convenient to do so, for the secret of the whole conditions of watering is simply that with all newly-planted subjects the roots cannot imbibe water fast enough to supply the means of a rapid evaporation, caused by a parching sun or a drying wind, to which, if our plants are not exposed, the amount of evaporation is reduced according to the protection given, and a corresponding amount of water only will be required.

As some of the best means of reducing the amount of evaporation, I

may instance the use of shading where practicable for bedding plants, and such others as may be in masses. For more distant or larger subjects, such as choice specimens of trees or shrubs of any description, or any number of flower beds, the garden engine is a most useful instrument. If this is brought to bear upon them, and every leaf-stem and branch gently damped by the force of the water from the delivering fan of the engine, it will check evaporation amazingly, and plants two or three times so treated during the height of a parching sunny day will endure drought much better than those that are constantly receiving a deluge at the roots, as it not only checks the escape from the pores of the plants, but it creates a moist atmosphere around them, most acceptable at such a season to plants that a force of circumstances have rendered susceptible of such trying weather. If you think, Mr. Editor, the old man's notions of the use of the watering-pot are acceptable, I may return to the subject again shortly.

THE MAN WITH THE BLUE APRON.

MIMULUS CULTURE.

The name of this plant is said to be from "Mimo," an ape, bestowed upon it because of the ringent or gaping mouth of the flower. The merest novice in botany will, at the first glance, discover that the Mimulus belongs to the natural order *Scrophulariaceae*, or Figworts, in which are grouped the pentstemon, calceolaria, antirrhinum, and other flowers similarly constructed. There are many useful species, and a few good varieties which it will be desirable to enumerate, and in naming them we shall add a few words on culture.

Hardy Species.—*M. rivularis* is the best of these. It makes a brilliant display of golden yellow flowers during June and July. Once planted on damp loam, it will spread to a larger patch every year, and acquire a most important character in the decoration of the garden. At the foot of a rockery, or in the common border, it is quite at home. As it dies down in autumn, the ground where it is planted should not be disturbed. *Glaberratus*, yellow; *guttatus*, spotted; *ringens*, blue; and *propinquans*, yellow are all useful for the border and damp parts of rockeries. *M. moschatus*, the "musk mimulus," is very hardy as an annual, usually appearing plentifully in places where it was planted out the previous year from self-sown seeds. But in mild winters the roots also survive and throw up shoots in spring. The best way to grow musk is as a frame plant. The soil should be light and rich, and the pots in which the plants have grown should be put aside, so as to be safe from frost, and kept moist till next spring. Then as soon as they begin to sprout, divide them and pot separate small pieces in fresh soil, in small pots, and place on a gentle bottom-heat, or in a warm corner of the greenhouse. They will soon fill the pots with roots, and must be shifted to larger and larger pots, according to the size of the plants required. For all ordinary purposes, however, 48-sized pots are quite large enough. By liberal culture musk may be grown to a height of three or four feet, and be one mass of bloom the whole season. It may be trained upright by means of a few light stakes put round the pot, and connected with strands of bass all round, or if planted in a basket may be allowed to hang down in festoons. The great secret of growing fine specimens is to use a rich soil, shade moderately, and give abundance of water.

Greenhouse Species and Varieties.—They may all be treated as annuals if sown early on a moderate hotbed, and as soon as up pricked out in rich light soil, and grown on in good greenhouse temperature. For a good bloom the same season, the latest time for sowing is the last week in February. As soon as the seedlings have made a good start after being potted singly in thumbs, give them rather more water than would be safe to the generality of plants in so young a state, and shift on as fast as they fill the pots with roots. When they are in 48-sized pots, place a saucer under each, and let that saucer be always full of water. They will drink it up and thirst for more, and grow with great luxuriance and make fine flowers. They will need shading when in bloom, and plenty of air, in fact, they may be treated nearly the same as herbaceous calceolarias from first to last, but must have more water. As the stems are very soft, and the flowers heavy, they must be neatly staked before they get untidy. As it is advisable to render the supports as nearly as possible invisible, neat painted sticks should be used. We have been accustomed to use lengths of No. 1 iron wire, painted a light green, for this purpose, and found them preferable to wood. When the plants are in bloom, any of superior excellence should be marked with tallies to propagate from. During August and September, take cuttings of three joints each, place half a dozen of these round a 48 pot in a compost of half leaf-mould and half loam, with an addition of silver sand sufficient to render the mixture light and friable. Plunge these pots in a gentle heat and keep close till rooted, which will be in about fifteen days, then pot singly in 60-sized pots, and in these pots winter them. When grown in quantity they are usually wintered in the cutting pots, and have a shift at the end of February or early in March, into 32-sized pots, well drained and filled with a mixture of leaf-mould, turfy loam, and rotten dung equal parts. At the end of April or early in May these may be again shifted in pots of 12-size, in which to bloom. They will require abundance of water, and may have saucers to keep the roots constantly in action. Any required extra fine for exhibition should have liquid manure once a week, but without this help the plants will flower finely if grown as otherwise directed. Of course the cultivator may shift on seedlings to the same size pots as plants from cuttings, but generally it is best to flower seedlings in 48-size, and grow into specimens only selected varieties known to be worth extra culture.

Properties and Hybridizing.—The attention of the cultivator should be chiefly directed to the form of the flower; in habit and colour it can scarcely be improved. Flowers that collapse are not worth growing, however fine their colours, except it be to furnish pollen for hybridizing flowers of good shape. The broader the segments and the smoother the edges, the higher will the flower rank in the eye of the florist, and deservedly so. In selecting varieties to propagate from cuttings, or to produce seed, give the preference to those that exhibit an expanded flat surface with small spaces between the petals. As regards colours, these should be bright and decided; the markings sharp on clear grounds; yellow is the most common hue, and white the most rare. In every endeavour to improve the mimulus, the hybridizer should select for the seedling flowers those that have thick broad petals, and that most nearly approach a circular outline, and for pollen, flowers that are the most brilliantly and regularly coloured; if the pollen flower is also well formed there is the greater chance of a pod of seed worth saving. *M. cardinalis* is the parent of the best show varieties we possess. The original species

grows to a height of two feet, and produces fine scarlet flowers. Seedlings vary to all the shades of rose, ruby, maroon, pink, and crimson, and if crossed with *roseus*, *Smithii*, and *variegatus*, some very showy strains may be secured. *Cardinalis* is a native of California, and was introduced in 1835. *M. roseus* has small flowers of regular shape, with yellow throat and bright rose petals; it is one of the most beautiful in cultivation. Mr. Douglas sent seeds of this to England from North California in 1831, and it was first flowered in the gardens of the Horticultural Society. This is strictly a perennial, and is not so easily cultivated as most others of the genus. The best method of treatment is to keep it constantly in the frame or greenhouse, potted in turfy loam three parts, sandy peat one part, and leaf-mould one part, and the pot always in a pan of water except during cold winter weather. It is easily increased by cuttings and occasionally ripens seeds. *M. variegatus* is a native of Cbili, introduced by the Messrs. Loddiges. This is described in some works as white and rose, but this is not correct. The throat is a pale canary, and the segments of the flower are deeply tipped with rosy purple, the remaining parts being a rich gold yellow. This species seeds freely, and is not at all difficult to cultivate. *M. glutinosus* is now a rare plant. It is the most shrubby of all, and well worth recovering for crossing with good varieties of weak habit. *Smithii* is a fine hybrid raised some years ago by Mr. George Smith from *rivularis* as the male parent and *variegatus* as the female. The flower is large, the ground colour orange yellow, at the tip of each petal is a large brownish crimson blotch, and there are small spots of the same around the throat.

Twelve Finest Exhibition Varieties.—Alexander Haig, light lemon, dark maroon margin; Danecroft Beauty, white with crimson blotches; Distinctus, lemon, deep crimson margin; Grand Sultan, pure white throat, black margin; Lydia, bright yellow and crimson; Magniflora, white and cherry; Mrs. Dickson, yellow, crimson blotches; Mrs. E. Lockart, white and maroon; Raphael, pure gold margin and deep claret; Spotted Gem, gold and maroon; Sultan, yellow and purple; Symmetry, straw, spotted with cherry red. Mr. Bull's *Duplex Mimulus* should be in every greenhouse, for it is not only beautifully coloured, but has a coloured calyx, so that when the flower falls there is yet a flower left.

Mimulus for Bedding.—All the hybrids are adapted for bedding, and, as a matter of course, the dwarfest are most easily managed. On hot dry soils they are useless; the foliage loses its proper colour, and the plants are eaten up with red spider; but on a cool, moist loam and in damp places, where many kinds of bedders would be unhappy, the mimulus is quite at home. When any selected hybrids are grown for bedding, they may be kept in their cutting-pots till May, and then be turned out and sheltered from the sun, and kept well watered till rooted: generally the colours come much finer out of doors than under glass; this is especially the case with *rivularis*, which is a charming plant for a mass, but unfortunately fugacious. Good beds may be made of seedling plants from February sowings, but there will be no uniformity of colouring. *Floribundus*, *parviflorus*, and *moschatus* make better clumps when grown in moist and shady beds of peat, but the last named should be used rather for its odour than its colour; for however profusely it may flower, it is by no means effective in a mass. It is otherwise with *M. cupreus*, which is one of the finest bedding plants we possess. It is perfectly hardy, and can be grown from either seeds or cuttings, and requires precisely the same treatment as *Lobelia speciosa*. It grows four to six inches high, and produces a perfect blaze of fiery flowers. A damp shady bed suits it best.

J. HARLAND.

NOTES ON BEDDING.

You may depend upon it that we cannot overdo it in the use of plants which produce a desirable effect by means of their leaves only, because then we have in the bed or line one uniform colour, instead of dottings of red, white, or blue on a ground of green. Take a distant view of a bed of geraniums, and as you see the flowers *en masse*, the effect is decided and satisfactory; you are in fact delighted, and so you go closer, and it is like being at a conjuror's elbow, and you no longer enjoy the delusion. Now you see the scarlet broken into splashes, and the green of the leaves spoils it. The combination of the green and scarlet produces on the retina a sort of neutral brown.

If you do not believe it, mix red and green together with water-colours, and report to us on the result. But pluck a thousand trusses of scarlet geranium, and stick them in close together in a bed of dark soil, and you see at once how one colour on a dark ground satisfies the eye, whereas two colours, and those complementaries, cause dissatisfaction when both are seen without partiality to either.

It follows (and if it does not appear to follow, we can prove the point by other arguments) that a plantation of flowers set out parterre fashion, should be viewed as nearly as possible in a horizontal line, or at an angle just low enough to take in the view of the furthest of the colours. Now to plan out your geometric garden consider first the several points from which it may be viewed, also reasonably, one angle and one of those points should be the drawing-room windows. From one of these points make your plan on this principle, that the colours in front are to contrast harmoniously with those next in the rear, and so on to the further side of the whole is to be a composition at which a true artist will clap his hands with delight. Hundreds of garden plans pass through my hands every year, and I have one uniform way of judging them. I take a box of water colours, and draw on a slip of paper the predominant colours in stripes, each in the proportion it has on the plan, and if they do not harmonize on the paper they will not on the ground, and this I have proved again and again in practice. When I go to Kew or Sydenham, or anywhere else, I make a plan in pencil on a page of my note-book. Not that I really want it, for I have a tremendous memory, but to make sure in case of a nice point arising out of some matter I did not trouble at the time to fix on the wheel of my sensorium. When I get home I paint out the pattern, and I invariably find that what I thought good on the ground will be good on the paper. It ought to be so, for orange and violet look well side by side in a flat mosaic, in a lady's bonnet or dress, in a bouquet, and in a scheme of bedding. Well, you set out your colour, and you find that for your centre you want a neutral tint, to prevent the eye being drawn that way, and to prevent the scheme shrinking, for it will shrink almost to nothing with strong colours in the centre. Now try again with the colours; make mere daubs of red, blue, yellow, crimson, &c., close together or meeting closely. What a mess it will be! But take some strong grays, blues, whites, and ambers, and with these paint sharp lines between the strong colours to separate them. Prosto! how the scene is

changed! If two colours come side by side that do not very well harmonize the divisional line makes them tolerable. Put amber on your purples, whites on your blues and scarlets, blue on your orange, gray anywhere. By the way, gray is a good relief to any strong colour, so gray edgings come in generally, and are wonderful for geraniums. Now you see how necessary it is to colour your ground as the Moors coloured their pavements. Pale green will light up any combination of deep, rich colours, such as purples, crimsons, and scarlets, and you have that always at hand in grass turf. But you say, "Why, then, find fault with the green leaves of Tom Thumb when a mass is closely inspected?" For this reason, that the scarlet flowers are sprinkled on the green. But when a mass of scarlet has a green boundary, the green is pure green and green alone; if it is even dotted with daisies, you ought to be ashamed of it. But go on with the colouring. Tear up the paper on which you made the daubs for illustrating the use of edgings, and paint another. Put in the centre a patch of creamy white, and suppose that to be Flower of the Day geranium. Round that put patches of lavender, cerise, and flesh; these are your semi-tones; and you can do them in ageratum, geranium, heliotrope, and verbona. Edge these with half tones opposed to the half tones of the mass. Now surround them with patches of orange, purple, scarlet, and crimson, in the order named, all round, and edge these with blue and silver, and the deed is done. From whatever point you view the group it will be harmonious. You can do all these in calceolaria, geranium, verbona, and petunia, and the edging will require cerastium, lobelia, Stachys lanata, Gnaphalium lanatum, and Dactylis. As easy done as said. You only want plenty of plants, and courage to use them in sufficient quantity, and if you can't do that, level the beds down, and sow grass seeds, and make up your mind that bedding must be bedding, and not patching. Bob.

Calendar.

WORK FOR WEEK COMMENCING MAY 11.

Kitchen Garden and Frame Ground.

BEANS for a late supply may be sown. Early crops will need the earth to be stirred between the rows, to keep down weeds and promote the vigour of the plants. On hot stony soil it will be well to open a trench between every two rows, and fill this with water, after which close the trench, and draw earth to the stems of the plants.

BROCCOLIS advancing in the rough leaf to be pricked out on light rich borders. Occasionally dust the plants in the seed-bed with lime, to preserve from slugs. Sow again for succession such sorts as *Walcheren* and *Self protecting*.

RIDGE CUCUMBERS.—The growth of cucumbers on ridges is a very simple matter, and it may be accomplished with or without hand-glasses. If hand-glasses are used, the plants may be got out at once; but if not, next week will be full early enough. Any moderately good light loam will grow them well; but fermenting material is necessary to produce a gentle bottom-heat. The trenches are made of various widths, some growers preferring to make them up as four-foot beds; but the usual and best measure is two and a half feet. The soil is taken out to a depth of one foot, and laid on each side; the trench is then filled to a foot above the surface with fermenting dung in a condition somewhat subdued as to heat by previous turning. Leaves, litter, grass mowings, and other fibrous material, may be mixed with the dung to increase the mass. If manure has to be purchased for the purpose, rotten dung will be at once the cheapest and the best, for there will be some bulk of manure for money, and it will give a good steady heat. When to cover the manure with soil must depend on the nature of the fermenting material. If rank and hot let a few days elapse; but if rotten dung is used, the soil may be put on at once, and two or three days after the plants may be inserted and covered with hand-lights.

PEAS to be sown for succession. *Ne plus Ultra* is one of the best to sow now. If any serious failures in the general crop, sow a few rows of the earliest sort. Generally speaking peas look poor, and many early sowings have perished outright.

BETT to be thinned; generally speaking, a foot apart is the proper distance, but some of the large-growing kinds must have fifteen inches, and several of the dark-fleshed small-growing kinds will do well at nine inches. Plenty of time yet to sow for neat small roots.

CAPSICUMS AND TOMATOES may be planted out on warm borders and on walls.

CELERY to be pricked out in frames and on warm light borders. Trenches may be dug out for the earliest crop, so as to be ready for planting as soon as the weather becomes showery.

ENDIVE.—Sow the first batch.

KIDNEY BEANS to be sown for succession, the rows two feet apart, the seed nine inches apart in the rows. Kidney beans are generally sown as thick as spinach, and the crop is less than may be had by using a tenth part of the seed.

LETTUCE to be sown for succession. Plant out on well-manured ground from seed-pans and boxes. In places where summer lettuces commonly bolt, it is necessary to manure liberally, and sow where they are to stand, as the check occasioned by transplanting greatly favours the bolting.

ONIONS FOR PICKLING to be sown now on poor soil. The favourite sort is *Silver-skinned*, but *White Globe* is also a good sort. Sow thick, so that the bulbs will form a pavement.

RHUBARB to have flower-heads removed. It is believed by some that the flowers make a delicate dish if cooked just before the flowers open. We have tried it, and have unpleasant remembrances of the horribly insipid taste of the dish, and we very much doubt its wholesomeness.

VEGETABLE MARROWS may be planted out, provided the beds are in a nice warm condition, and the plants are strong. After planting, put hand-glasses over, or put baskets or large pots over at night for a time, in case of frost. But if the beds are not in a state of steady fermentation, or if the plants are not strong, defer planting. But in any case get the beds ready, if not done already. Proceed in the same way as described for cucumbers, but make the beds four feet wide.

THIN every kind of crop where there is anything like crowding. Spinach, beet, turnip, parsley, &c., will be the worse for remaining thick. The same with all kinds of fruit. Gather gooseberries as soon as they have flavour enough for tarts, so as to give those left on the trees a better chance to swell. All fruits of the plum tribe are useful in a green state for culinary purposes as soon as they have attained some size, and

the thinning should be regularly proceeded with, to lessen the demands upon the trees.

CAULIFLOWER to be sown for succession. At the first indications of rain, hoe between the advanced crops, to give the roots the full benefit of showers. Cauliflowers that were planted close to winter should be thinned by taking every alternate plant as soon as there is a small head formed; this will give room for the production of fine heads for succession.

Flower Garden.

ASTERS must be pricked out where they are to flower, or be potted singly in light rich compost. The frame is the best place for potted asters; those bedded out will want the protection of mats should the weather become cold again.

BALSAMS.—Treat as advised for asters; some of the early-sown plants will be showing bloom now. If it is desired to grow them larger before flowering, nip the flower-buds off, and shift the plants to the next size pots.

HARDY HERBACEOUS PLANTS going out of bloom may be propagated from cuttings or seeds. Double Wallis, Alyssum, Iberis, spring Phloxes, &c., &c., should be grown in quantity, and the only safe way to secure stock is to put the cuttings into a gentle heat.

PAEONIES need the support of sticks to prevent the blowing over of their heavy flowers. A heavy soaking with liquid manure will do very much towards improving the bloom.

Roses are growing freely, and in many cases a few of the earliest buds are showing colour. If not already mulched, let it be done at once, and if it be possible to soak the ground first, all the better.

PHLOXES struck from cuttings now will bloom well in autumn; strong stools in the border will need thinning to reduce the number of shoots to a few manageable leaders, which are to be staked neatly and separately. Phloxes are now being grown in pots, but are scarcely the best of subjects for that method, though it is convenient for showing, and enables the exhibitor to put up complete plants, which are always preferable to cut blooms when it is possible to show them.

BEDDING-OUT.—Dull weather is the best for this work, and if it can be done just before rain, much labour of watering will be saved. But when the ground is absolutely wet, bedding cannot be done properly, and had best be deferred a few days. When the plants are counted off and sorted for their places, let them go nearly dry; they will then turn out better than if the balls are wet. Plants that have not quite yet filled their pots with roots turn out in complete balls, remove the crocks, and close in without breaking the balls; but those that are absolutely pot-bound must have the ball slightly loosened, to enable the roots to push out easily into the free soil. Plants brought in from nurseries should be put in a cold frame for a week before planting them, and the last day or two keep them wholly uncovered, to get quite hard for planting. If there are no frames to spare, let them lie about for a few days anywhere moderately sheltered. If these precautions are neglected, the result will be a crop of yellow leaves, and the deferring perhaps a fortnight of the season of full bloom; so a proper amount of care and a little reasonable delay will be a gain of time in the end. In planting, put out Calceolarias, Antirrhinums, Penstemons, Stocks, and other of the hardiest kinds first. Geraniums, Verbenas, Petunias, and other soft-wooded plants from spring cuttings, will be the better for bedding if they have a little more care under glass. There is nothing gained by turning them out before they are strong enough for the purpose. Strong plants of all kinds, except Lantanas and tropical foliage plants, may be put out now with perfect safety; but there is nothing gained by putting out miserable bits of plants from thumb-pots, that require a shift to 60's, and a little more greenhouse culture to give them size; nor is there any gain in planting until the plants have been properly hardened in the pots by exposure to the atmosphere for a fortnight, the latter part of the period to be exposed night and day. Now is a good time to top such plants as will bear it, and put in the cuttings for a supply of plants to bloom in the house in autumn. Petunias, Verbenas, Geraniums, and Heliotropes struck now, and kept from blooming prematurely, will make nice plants by the middle of July to flower from thence to mid-winter.

PANSIES.—This is a good time to strike cuttings for a good autumn bloom, and to secure pot plants of choice kinds to keep over winter for spring cuttings. The side-shoots and very young tops of the leaders root quickest and make the best plants. Old stems that are hollow should never be used unless the case is one of desperate necessity. Florists' Pansies are generally grown in too light a compost, and hence there is often a lack of substance in varieties which in a firm soil are as stout as cardboard. Seed sown now will bloom in ten weeks, and afford plenty of time to prove them, and secure a few cuttings of the best.

WALKS that are sour, worn down, or in a bad state as to levels, &c., ought to be put to rights now. It is a good plan to get the bedding done, and while the plants are getting hold of the ground, turn the walks and put a new coat of gravel on. This gives the garden a bright look at a time when it will be most enjoyed, and it is astonishing how much better flowers look when grass and gravel are first-rate. Besides, by gravelling now, or within a few weeks, the walks get well set and hardened before winter, which is a matter of some importance.

Fruit Garden and Orchard House.

STRAWBERRIES are blooming freely, and it is time now to spread litter to prevent the fruit becoming gritty. There is nothing so good for the purpose as cocoa-nut fibre refuse, as it is always clean and moist, and vermin do not like it.

WALL FRUIT.—It should be remembered that the fruits of peaches, nectarines, &c., &c., need a little shade, and of precisely the same kind as is required by grapes—namely, the shade of their own leaves. Hence in thinning foreright shoots, leave such as give shade to fruit, having rather to regulate than to strip the trees.

GOOSEBERRY TREES beset with grubs can only be satisfactorily dealt with by hand-picking. The process may be expedited by placing a sheet under the trees, and by a smart rap on the stem great numbers may be shaken off.

Greenhouse and Conservatory.

CONSERVATORY PLANTS are growing freely now, and must have plenty of air and water. The more air is given, the more light may be allowed, as it is seldom any scorching occurs with plenty of air. Still it is impossible to avoid the use of shading, but let it be used as little as possible, and so as to benefit such plants as most need it. Climbers want attention to keep

them in order, and generally speaking a heavy watering at the root will do them good. Old hard-leaved and hard-wooded conservatory trees are generally producing a new crop of scale at this time of year—a thing not to be desired.

AZALEAS that are out of shape and leggy may now be cut back to advantage. At the same time they must be turned out of their pots, and the balls reduced and repotted firmly in smaller sized pots, and at once put into a kindly moist heat until they break freely. Instead of giving water at the root frequently, syringe the stems until they are growing freely, then give the roots plenty.

NEW HOLLAND PLANTS going out of bloom must be cut back to keep them bushy. Species of rambling habit must be trained in order to make compact specimens of them. Any that need repotting to be attended to, using peaty soil containing abundance of siliceous grit.

PELARGONIUMS showing their flower-buds will be benefited by frequent doses of weak liquid manure. Fresh sheep, deer, or cow-dung, one peck to seven gallons of water, to be used when quite clear, will answer admirably. Keep the plants as near the glass as possible, give air freely, and use the syringe, not only over the leaves, but on the stems and branches underneath, which is a grand preventive of fly.

CAMELLIAS that have finished growing for the season to have less water and more air. They must not go absolutely dry, because that would punish them, but to have only as much moisture as will keep them from flagging. It is too soon to put them out yet; so give them airy positions in the house.

EPACRIS that have flowered must now be repotted, the soil to be sandy fibry peat. The strong-growing kinds must have a large shift. Use plenty of drainage carefully packed, and place the plants in a turf pit for the summer, and shade during midday. As the new growth progresses, pinch it back to promote a bushy habit. Now is a good time to propagate from points of new shoots an inch and a half long. Dibble them into pans of silver-sand, and cover with bell-glasses.

Stove and Orchid House.

STOVE PLANTS require abundance of atmospheric moisture, both to promote a free growth and to keep down vermin. Many valuable plants may be propagated now from cuttings of the new growth, and this operation must be attended to in good time, especially in the case of plants required for next winter's flowering.

Forcing Pit.

FORCED FRUITS, such as cherries, peaches, nectarines, &c., now ripening should have the lights drawn off to give the fruits full exposure to the air. This will retard the ripening a few days, but that will be fully compensated by the improved flavour of the fruit. The taking off the lights, however, must be regulated by the state of the weather; if cold and damp, use a little fire-heat, and give air in the usual way.

PEACHES under glass are now well furnished with wood for next season, and the cultivator will have to select now the shoots that are to bear next year's crop, instead of waiting till the winter pruning. Tie in betimes, and thin away all superfluous growths, as if the trees are crowded none of the wood will ripen properly.

MELONS will be enjoying plenty of sun-heat now, and if the heds still give a tolerably good heat it may not be necessary to line them again; but if it is some time since the heds were lined, and the fermentation is nearly at an end, put a fresh lining. Use the syringe moderately to keep a healthy foliage.

VINES.—In the early houses there will be good ripe bunches now of several sorts, and as it is desirable to keep them as long as possible, so as to cut them fresh and fresh, give abundance of air and very little water. In houses where vines are coming into bloom use the syringe with caution, and assist with the hand all shy setters. Vines are thirsty now, and all inside borders must be abundantly watered.

PINES established to have very little shade, and plenty of air as weather permits. Shift succession plants as required, and give very little water at the root until they have begun to take hold of the new soil. Put them on a good bottom-heat, and shade from eleven to three.

CHERRIES to have plenty of air and a rather dry atmosphere when the fruit shows colour. Trees swelling their fruit to have plenty of water. Look out for black fly, and keep it down if possible by syringe rather than by smoke. Sometimes we find a few shoots only affected, and once or twice dipping them in weak tobacco-water usually suffices to cleanse them thoroughly.

FIGS must have plenty of air when the fruit is ripening, and at the same time the fruit must be kept dry.

CUCUMBERS in frames are now hearing freely, and will want abundance of water. If the heat is declining, reline the heds.

ON THE NUTRITIVE CONSTITUENTS OF WATER.

By PROFESSOR SCHULZ-SCHULTZENSTEIN.*

(From the Journal of the Royal Horticultural Society.)

In the first division of this treatise (Tr. Pruss. Hort. Soc., vol. xx. part 2, p. 354), I have spoken historically of irrigation as practised in the culture of plants, and have shown, from the historical facts of cultivation, in contradiction to the theory of their nourishment by means of carbonic acid derived from the air (as first stated by Ingenhousz, in his treatise "On the Nourishment of Plants and Fertility of the Soil," and afterwards by Senchier in his "Physiologie Végétale," by Th. de Saussure in his "Recherches Chimiques sur la Végétation," and recently reproduced by our countryman Liebig, in opposition to the notion of the nourishment of plants being derived from the soil), that the nutritive constituents are for the most part dissolved in water, that water is the only vehicle of nutriment, and that the theory of nourishment by means of air is in the most decided opposition to all practical experience in horticulture and agriculture, and more especially to the effects of manure on growth. I now purpose to show that the nutritious constituents of plants are separated from the soil by means of water, and that the water contained in the soil, and that of springs and wells, is loaded not merely with

saline, but more especially with the humous elements of the ground, and that the humous organic constituents dissolved in water furnish the true nutriment. Liebig promulgated the notion that the waters of springs and wells contain no organic constituents, or, at least, none worth mentioning, and adduced the Selter-water as a proof, which, like many waters springing from deeper primitive formations, seldom contains humous or bituminous matter in solution; but the consequent conclusion that all other spring and pump waters are void of organic constituents is quite erroneous. This appears from a comparison of the different chemical analyses which we possess of the waters of numerous medical springs and baths, in which, besides the saline constituents, there are also organic constituents of a more or less decided humous character, which, for the most part, are reckoned under the name of extractive matter.

The waters of Wiesbaden, for instance, contain, according to Richter, 1.75 gr. of organic extract in the pound; those of Hermansbad, near Moscow, according to Hermbstaedt, 1.5 gr.; those of Seidschütz, according to Steinmann, 0.35—0.42 gr. of humous extract; those of Wildbad, in Baireuth, 0.6 gr. of extractive matter, according to Martius; those of Kreuth and Tegernsee, in Bavaria, $\frac{1}{4}$ gr. of humus in the quart, according to Vogel; those of Beringerbad, in the lower Hartz, 0.5 gr. of extractive matter in the pound, according to Bley; those of Bocklet, near Würzburg, $\frac{3}{4}$ gr. of humous extract per pound, according to Goldwitz. In many bath-waters there is contained a nitrogenous extractive matter (an animal-vegetable substance, crenic acid of Berzelius). For instance, the waters of Schmekwitz, in Bautzen, contain 6.5 gr. of nitrogenous extractive matter, 10.8 gr. of saponaceous matter, 1.3 gr. extractive matter in 30 lbs., according to Picinus; those of Châteaufort, in Puy de Dome, and Enghien, near Montmorency, contain, according to Fremy, 0.3 gr. per pound of animal-vegetable matter. The glairine (Zoogen, Gimbl.), a gelatinous matter in the sulphur-springs of Barèges, in the Pyrenees, is, according to Anglade, of a similar character, and is so abundant in the sulphur-springs at Aachen and Burtscheid, according to Mohrheim, that the daily produce amounts to about 1000 lbs. A similar organic substance is left after the evaporation of the spray of the Karlsbad water on the margin of the spring, and affords a matrix for the development of the vast masses of *Oscillatoria* which are found there. The mother-lye of the water of the Baltic contains, according to Pfaff, two kinds of extractive matter; and in many other waters, as in those at Northeim, near Göttingen, according to Wurzer, and at Warmbrunn, in Silesia, according to Tschörtner, there is resinous and gummy extractive matter. The Berlin spring-waters contain from $\frac{3}{4}$ to 1 $\frac{1}{2}$ gr. of humous extract per quart. All these waters, therefore, when kept are subject to more or less rapid decomposition, and give rise to Infusorial and Conferval organisms.

Now, since all river-water is derived from springs, it is clear that it must be rich in humous and extractive matter. As regards the quantity of humus in river-water, we have at present only very confined observations; but little attention was given to the subject so long as the important agency of the quantity of humus contained in water upon vegetation was unknown. It is, however, sometimes so great, that it communicates a yellow, or in great depth a coffee-coloured, or even dark-brown tint. The black streams first attracted attention in America, where the Rio Negro, or Black River, derived its name from the dark colour of the water, as also many tributaries of the Orinoco. The Atapaho, Guainia, and Tuamini are of a dark coffee-brown. Lyell states, in his "Travels in North America," that in the vast swamps in the narrow atlantic plain of North America, especially in the Great Dismal between Norfolk and Welden (between Virginia and North Carolina), there is a lake seven miles long and five wide whose waters are of a dark brown from the dissolved humus.

The "blackwaters" (Karassu) which are often found on the mountains of the East, derive their name equally from the brown or black colour of their waters in consequence of the dissolved humus.

Very recently, Junghuhn, in his travels in Sumatra, directed his attention to the "blackwaters." He says, "The mountain-streams of the Batta land of Sumatra, especially on the tableland of the provinces of Sieperok and Tohah, have a coffee-brown tint. In the heds of the river shaded by forests, their water appears very dark, but of a golden-yellow in a transparent glass. This tint is universal in the interior of Sumatra; but it is most striking in the high table-land, where the slight inclination of the surface in the dark primeval forests gives rise to frequent inundations, and where, besides the vegetable substances which rot upon the moory ground, a quantity of root-threads are irrigated with water, which, impregnated with the extractive matter which enters into their composition, forms a kind of cold infusion. The water may nevertheless be drunk without injury, and is void either of taste or smell." ("Travels in the Batta Land of Sumatra," i. p. 256.)

It is rather surprising that the dark waters of Europe should hitherto have been almost entirely overlooked, notwithstanding their appearance in almost every river which runs down from the Hartz, especially the Brocken. The water of Ilse, near Ilsehurg, is at some deeper parts of the river almost coffee-brown. If we follow the river towards the heights of the Brocken, we remark that almost all its sources are derived from dark peat moors, from which the water streams coloured brown from their dissolved humous constituents. The same is the case with the other rivers of the Upper Hartz, especially on the north side of the Brocken. Almost all the fresh-water lakes of the marsh districts of Northern Germany are black from humous matter.

I have endeavoured by means of evaporation to ascertain the quantity of humus in different German river-waters. Four pounds and a half of that of the Spree yielded, on evaporation, 4 grs. of solid residuum, of which three consisted of salts, the other of a humous extract. The Spree water is, for the most part, not entirely colourless, but has a yellowish tint; on evaporation it acquires a brown tint as it becomes more concentrated. Eve y. pound of it contains $\frac{2}{3}$ gr. of humous extract; a cubic foot, therefore, or 66 lbs., contains 14 $\frac{2}{3}$ grs. According to observations made at the Berlin Mills, 576 cubic feet pass every second at low flood, 2,016 at high flood, the mean of which is 1,296.

At low flood, then, there are 2,072,600 cubic feet per hour, or 49,766,400 cubic feet per day, or in weight 29,859,840 cwt. This, then, contains 49,766,400 \times 14 $\frac{2}{3}$ = 729,907,200 grs. or 422 cwt. 100 lbs. of humous extract, which quantity passes through Berlin on its way to the sea.

The turbid water of the Elbe, collected at Magdeburg in August, 1851, became clear when allowed to settle, with a very slight yellow tint. Four pounds of this evaporated to a coffee-brown fluid; and thus, when freed from the sediment of salts of lime and silicates, yielded 6 $\frac{1}{2}$ grs. of humous extract, free from water. The Elbe water is therefore far richer in humus than that of the Spree—the richest, indeed, of all which I have examined, although it is by no means so deeply coloured as the Hartz water. It contains more than 1 $\frac{1}{2}$ gr. of humous extract per pound, which in the cubic foot amounts to

* Translated from the German in vol. xxi. part 31 of the Transactions of the Horticultural Society of the Prussian States.

This translation was prepared in part some years since by the editor, at the request of Dr. Lindley, for the former series of the Journal of the Horticultural Society of London, but was not published in consequence of its discontinuance. It is to be expressly understood that the translator is not responsible for any of the opinions expressed, much less for the occasionally somewhat severe criticisms.

107½ grs. If we assume that 4,000 cubic feet per second pass by Magdeburg to the sea, which is double that of the high flood of the Spree, we have for the twenty-four hours 14,400,000 cubic feet, and this will supply daily, if 100 grs. of *humus* only be reckoned to the cubic foot, about 1,798 cwt. of extractive matter which can be appropriated to the nourishment of plants. We see then how rich the waters are in nutriment.

The water of the Ilse, at Ilsenberg, collected in August 1851, gave, after the evaporation of 4 lbs., 2 grs. of humous extract, which is ½ gr. per pound.

The water of the neighbouring Ecker, which is browner than that of the Ilse, in 4 lbs. yielded 24 grs. of very dark humous extract.

Two quarts of water of the black Elster, collected at Herzberg, gave, after evaporation, a treacle-brown fluid, which, reduced to perfect dryness, gave ¾ gr. of saltetro and 2½ grs. of humous extract.

The Rhine, at Basle, passes 13,000 cubic feet of water per second (which, reckoning ½ gr. of *humus* to the pound, contain 56 lbs.), 3,360 lbs. per minute, 1832 cwt. per hour, and 43,968 cwt. per day.

The Ganges, above its bifurcation at the Delta, near Sicligully, passes in April, according to Prinsep, 21,500 cubic feet per second; at Benares 20,000. If there is only ½ gr. of humous extract per pound, or 33 grs. per cubic foot, we shall have

$$33 \times 20,000 = 660,000 \text{ grs.} = 85 \text{ lbs. of } \textit{humus},$$

5,100 lbs. per minute, 306,000 lbs. per hour, and 66,764 cwt. per day.

The Indus, according to Prinsep, sends out at its bifurcation at Tatta 80,000 cubic feet per second—that is, four times as much as the Ganges, which yields 267,056 cwt. of *humus* per day, if the water has only the sixth part of the nutritious matter contained in the water of the Elbe.

The Mississippi, in the rainy season, passes 550,000 cubic feet per second—that is, nearly eight times as much as the Indus; and supposing the same proportion of *humus*, it sends daily to the sea 2,136,000 cwt. of *humus*.

Since *humus* contains every constituent necessary for the sustenance of plants—carbon, hydrogen, oxygen, nitrogen—the possibility of their nutriment by means of the *humus* held in solution by the water contained in the soil and streams is proved. We must, however, first examine the other views which have been held respecting the agency of water in the nutriment of plants.

Liebig and the more modern chemical physiologists regard vegetable matters as hydrated carbons in which water is condensed and combined with the carbon of the carbonic acid which has been received as nutriment. In this case the hydrogen and oxygen must exist in all vegetable constituent parts in precisely the same proportions in which they are found in water. This is allowed by Liebig and many other chemists, since they find in sugar and lignine nearly the proportions of hydrogen and oxygen which exist in water (eight times the weight of oxygen), so that they may be regarded as hydrated carbons. These assumptions, however, by no means accord with the very perfect modern analyses of starch, sugar, flax, and cotton, by Prout, Herrmann, Henry, and Ure, since all these substances show a greater or less excess of oxygen above hydrogen. Wheat-starch, according to Prout, contains 44 C, 49.42 O, and 6.18 H, being an excess of 0.2 of oxygen*. Potato-starch, according to Herrmann, contains 37.6 C, 55.76 O, 6.64 H, or 2.64 excess of oxygen over the constituents of water. Cotton-wool contains, according to Ure, 42.11 C, 52.83 O, and 5.06 H, or an excess of 12.35 O, which cannot be taken into the plant by the condensation of water.

In all other component parts of vegetables the elementary matters differ most decidedly from the proportions of oxygen and hydrogen in water, so that their origin from the condensation of water or the formation of hydrates seems quite impossible.

These vegetable matters may conveniently be divided into three sections.

1. Matters which contain a great excess of oxygen as vegetable acids. Citric acid contains, according to Berzelius, 41.36 C, 54.83 O, 3.8 H, an excess of 24.43 of oxygen. Malic acid, according to Liebig, contains 42.11 C, 56.14 O, 1.75 H, an excess of 42.14 O. Tartaric acid, according to Berzelius, 35.98 C, 60.21 O, 3.80 H, an excess of 29.75 of oxygen.

2. Matters which contain an excess of hydrogen, as resin, fat, and ethereal oils. Olive-oil, according to Gay-Lussac and Thenard, contains 77.21 C, 9.42 O, 13.36 H, an excess of 12.18 H. Camphor (a solid ethereal oil) contains, according to Liebig, 81.76 C, 8.53 O, 9.70 H, an excess of 8.63 H. Bees'-wax contains, according to Gay-Lussac, 81.78 C, 4.63 O, 14.07 H, an excess of 11.9 H.

Coal is one of the substances which has a decided excess of hydrogen. According to Ure it contains 75.76 per cent. C, 5.8-10 per cent. O, 5-6 per cent. H, 1-2 per cent. N. Since eight parts of oxygen in weight go to one of hydrogen in the formation of water, coal must contain 5-6 per cent. H, with 40-48 per cent. O, if it is a hydrated carbon; there is, therefore, an excess of 4-5 per cent. H.

3. There are, moreover, vegetable matters which contain hydrogen without oxygen, and are therefore anything rather than hydrates, as oil of lemons, oil of turpentine, india-rubber. Oil of lemons, according to Th. de Saussure, contains 86.89 C, 12.32 H, proportions which are absolutely contrary to the hydrate theory.

In De Candolle's "Physiology of Plants," as translated by Röper (vol. i. p. 364), we find a table of the elementary composition of many vegetable substances, from which an addition may easily be made to the instances which have been brought forward.

It is abundantly clear, then, that in the nourishment of plants, water cannot be used for the formation of hydrated carbons with the carbon derived from the carbonic acid of the air—that it must be useless in practical gardening and agriculture to attempt to nourish plants with pure water and carbonic acid without any humous constituents, as, in fact, all attempts to nourish plants with carbonic acid and water have miscarried.

Another view of the agency of water in the nutriment of plants is that of Berthollet, that a decomposition of water takes place in such a manner that the hydrogen is assimilated, but the oxygen set free. Saussure contradicted this completely, by showing that the water always runs unaltered through the plant, whose substance never increases by the assimilation of water. Notwithstanding which, Liebig, altogether unacquainted with Saussure's experiments, has sought a new explanation of Berthollet's theory, without troubling himself previously about the truth of the grounds on which it depends, and without making a single experiment on the subject. Liebig supposes that we must explain the decomposition of water after the analogy of the contact of zinc, water, and carbonic acid, where the zinc rusts in the water and the oxide of zinc unites with the

carbonic acid to form carbonate of zinc. The living plant, according to this view, acts as zinc in galvanic decomposition. This is an addition to Liebig's numerous explanations of circumstances of organic life, which are not present in nature, but are mere fancies, since decomposition and assimilation of water do not take place in plants, as appears from every experiment; but suppose there were such processes, the view which would make plants galvanic batteries is just as though a man should explain living growth out of decomposition, as indeed is sometimes the case, or compare a living plant with a stinking dungbill. The gardener and cultivator can only be puzzled by such lifeless explanations. His first principle should be that in the cultivation of plants he has to do with living beings, which he must keep alive, and not sacrifice by galvanic experiments.

If, then, water does not act by means of its chemical constituents as nutritive matter for plants, it can serve only as the means of conveying those nutritive substances which are dissolved in the water. We have spoken of the humous extract dissolved in the water as the peculiar nutritive substance of plants, and especially the different, in fact, nitrogenous humates which are found in it, and which, according to the experiments contained in the treatise on the discovery of the true nutriment of plants, are the only source of the oxygen which is exhaled under the influence of light. The ground is therefore the only magazine of nutriment for plants, the water the bearer of the nutritive matter dissolved out of the ground. All necessary ingredients for the organic formation of the tissues of plants must be contained in the humous matters, to which the mineral salts are only added as stimulants and promoters of assimilation. Carbon, hydrogen, nitrogen, and oxygen, and even sulphur and phosphorus, are contained in *humus* as matters of nutriment; plants need no nutritive matter from the air; they can imbibe only water from it in order to maintain their full flow of life ("Entd. der wahren Pflanzennahrung," pp. 140-141).

Liebig contends that *humus* cannot be the nutritive matter, inasmuch as he considers it impossible that the necessary quantity of humic acid or humate of lime could be dissolved in the water. An acre of land produces 10 cwt. of carbon in the corn or fruit, whereas the quantity of rain which falls upon an acre in four months is only 700,000 lbs., wherein only 3 cwt. of humic acid can be dissolved, and applied to the purposes of vegetation. The data are, however, all incorrect in this calculation. An acre of sand without any coating of *humus*, yields frequently a produce of scarcely 5 cwt., in which are only 2½ cwt. of carbon, and frequently yields no harvest at all; the quantity of rain-water does not determine in the least the fertility of the soil, since a poor soil is soon dried up after a quantity of rain, and a rich bottom during a long drought may keep itself moist by hygroscopic action; besides which, in every soil a quantity of moisture rises from beneath, which keeps it damp; the solubility, moreover, of humate of lime in water is by no means a measure of the quantity of carbon contained in it, as the greater part of the *humus* enters the plant as humous extract and perhumate of ammonia, which is very soluble in water.

Many persons have allowed themselves to be led astray by the question as to the origin of carbon, inasmuch as they imagine that originally at the creation there was no carbon in the soil, but merely carbonic acid in the air, and the *humus* arose at a later period from the decomposition of carbonic acid by means of plants. These suppositions, however, are quite erroneous. We find even in the primitive mountains carbon in the form of bituminous mixtures, as in bituminous talc, basalt, and lava, which contain 3 per cent. of inflammable constituents; and although coal was in the first instance a result of vegetation, there are in its neighbourhood, in all mountain formations, rocks containing carbon, whose bituminous constituents, being soluble in water, can serve for the nutriment of plants. Coal, moreover, as stated above, could not be formed of carbon and water, since it contains totally different proportions of oxygen and hydrogen from those which exist in water, and, moreover, much nitrogenous admixture whose presence is quite inexplicable on the carbonic-acid theory. On the other hand, water, after long contact, dissolves even out of the hardest bituminous rocks carbonic constituents, which in this form may be absorbed by plants. The more barren soil may be rendered fruitful by means of such water laden with nutritious particles, when it springs up from below. In this way it is also possible that, without any carbonic acid from the air, a sterile sand may acquire a coating of *humus* from a vegetable growth, induced by the surface-water, as the plants which have thus generated decay in the lapse of generations and increase the formation of mould. This can arise only from the fact that water is the medium of nutriment. The carbon of plants comes, then, from the ground, and not from the air. So it is in our modern world; and there is nothing to prevent its having been so in the ancient world. This truth must give a more natural direction to the theory and practice of cultivation.

Nitrogen plays an important part in the nourishment of flowering-plants, with which the influence of animal manure on the cultivation of flowers and fruits is intimately connected. Saussure, who made the discovery that rain-water contains a small quantity of carbonate of ammonia, expressed an opinion that the nitrogen of plants might be derived from the air in the form of carbonate of ammonia, that this substance might be developed from animal matters by putrescence and so dispersed in the air, and that manure decomposed entirely into carbonate of ammonia and carbonic acid. The quantity of carbonate of ammonia which is brought down by the rain from the air is, however, so small, that a hoghead of rain-water contains barely ½ gr.; while, on the other hand, rotting dung, as Davy has shown, evolves, besides carbonic acid, gaseous acetate and carbonate of ammonia, and is by no means entirely decomposed into carbonic acid and ammoniacal gas, but leaves behind a solid ammoniacal *humus* or mould—which is contrary to the views of Ingenhousz, who supposed the whole of the dung passed into a gaseous form by fermentation and putrescence, so that all the constituents which were nutritive to plants were communicated to the air; whereas, on the contrary, the nutritive properties reside, for the most part, in the mould which arises from the dung by means of decomposition.

The ammoniacal matter in the atmosphere is therefore extremely small, whereas that of the soil, and of many particular soils, is very large. Clay is the richest of all in ammonia. According to Baumbauer, the clay of the Zuidersee of Holland contains in a thousand parts .075-.078 of ammonia, which is about 0.13 or ½ per cent. The virgin forest-soil of Texas contains ¼ per cent. of ammonia; 100 lbs. of it contain 6 ozs. of sal ammoniac, or 2 ozs. of ammonia. According to Krockner's experiments, loam contains ½ per cent., sand and marl ⅓-⅓ per cent. of ammonia. In four acres of land having one foot depth of soil, containing ½ per cent. of ammonia, there are above 16,000 lbs., or 4,000 lbs. per acre. This quantity is greater than what is

* There is evidently something wrong about the figures here, as there is a defect of oxygen to the amount .02.—Tr.

given to land by manure. If an acre of land contains 120 cwt. of manure, supposing it to contain $\frac{1}{200}$ th of ammonia, there are only 66 lbs. of ammonia, whereas in the soil just mentioned there are 4,000 lbs. The dung is by no means effectual merely by addition of ammonia, but besides by the accumulation of humus as a ferment for other constituents.

The mode in which ammonia is formed in the soil is elucidated by the experiments of Kuhlmann on the formation of saltpetre, and has been further followed out by Mulder in his "Physiological Chemistry." Ammonia is formed in rotting porous matters, which evolve hydrogen, while the nitrogen of the air combines with the nascent hydrogen, as in the rusting of metals by decomposition of water—as, for instance, in damp iron-filings, in consequence of which iron-rust also contains ammonia. So porous fermenting soil without dung forms ammonia by the elimination of hydrogen, which at a later period is oxidized into saltpetre. Thus humate of ammonia is first formed in the ground, and then nitrogenous geic acid and crenic acid, which are absorbed as vegetable nutriment. Decidedly, therefore, the ammonia is not contained in the soil as carbonate of ammonia. The nitrogen, on the contrary, is combined with carbon, hydrogen, and oxygen, in the form of geic acid, crenic acid, humate of ammonia, which exist in vegetable nutriment thus formed. This nutriment is therefore a single substance, whose different constituents are by no means gathered together from so many quarters as Liebig supposes. Carbonate of ammonia is never assimilated by plants.

Another form in which nitrogen enters into plants is nitric acid, which is widely diffused in the soil, and generally combined with clay, magnesia, lime, potash, or soda—in many places so abundantly that in Egypt, Tibet, the East Indies, Italy, France, Spain, Hungary, and America the saltpetre effloresces and is easily collected. Nitric acid is formed by the oxidation of the ammonia, which is produced by the combination of the hydrogen eliminated from the soil with the nitrogen of the air. In consequence nitric acid, nitrate of lime, and saltpetre always exist in humous clay and limestone soils. The nitric acid is assimilated by the plants in the same way as other acids and humic acids, since the oxygen is exhaled in light, the nitrogen retained ("Entd. der Pflanzennahrung," p. 120).

Saussure's view, reproduced by Liebig, that the nitrogen of plants originates from the carbonate of ammonia in the air, and that all manures operate only by the formation of carbonate of ammonia, is therefore altogether erroneous, and can only lead to great errors in practical farming. Liebig's theory of manures runs throughout on the evolution of carbonate of ammonia from the dung, and the addition of gypsum in order to its fixation. It is supposed that the effect of gypsum depends only on the fixation of ammonia. It is plain, from practical experiments on the effect of gypsum in horticulture and agriculture, that this view is altogether wrong. Gypsum promotes the growth of the leaves and stems only of leguminous plants, as clover and peas, but never the blossoming and ripening of the fruit. On the contrary, gypsum, in consequence of the continued luxuriant growth, hinders the formation and ripening of the fruit, and therefore is very injurious in the cultivation of peas in fields, since these plants, when strewed with gypsum, continue green for a long time and produce with difficulty only a little seed. We have also shown that no neutral salts, and therefore neither gypsum nor sulphate of ammonia, can be decomposed and assimilated by plants.

Ammoniacal, especially nitrogenous, matters have precisely the contrary effect on vegetation: they promote, that is, the blossoming and formation of fruit, and impede the growth of leaves and stem. We may therefore, by manuring, push the production of fruit and flowers, in fruit-trees to such an extent that they will at last perish, especially in dry soils. I have myself seen young pear and plum trees, in certain years, perish from over-manuring. Gypsum never produces this effect, whereas if gypsum operated by the fixation of carbonate of ammonia, it must have the same effect as animal manures.

(To be continued.)

Correspondence.

THE MOON AND THE WEATHER.—I observe you had inserted in your very valuable publication the communication I made respecting certain days of the moon being the indices of the weather for almost the remaining days of the moon. The past month I thought would be an exception. My reason for thinking so was from the extraordinary continuance of wet which we had hitherto endured. I now send you an extract from my journal of wind and weather we have experienced in this part since the 3rd day of the last moon. I do so because theories (if this can be called one) are all very well, but of little value unless practically illustrated. For once it may be well, but after an example any persons interested can inquire for themselves. The first day of the new moon was April 4th, 10:4 p.m., consequently the fourth day (the first to observe) would be the night of the 7th until ten o'clock on the night of the 8th. The record is as follows:

- April 7. Wind W., rainy night.
- " 8. Wind W., windy and wet.
- " 9. Wind W., fine but windy, showery evening.
- " 10. Wind W.S.W., fine, one shower.

These are the indicating days, and on each day there was rain, more or less. From this I presumed we should have generally showery weather, with occasional fine days and some heavy winds.

- April 11. Wind N., day fine, shower.
- " 12. Wind S.W., day fine.
- " 13. Wind S.W.S. — W.S.W., rainy.
- " 14. Wind S.W.S., rain, wind violent.
- " 15. Wind W.N.W. showery, otherwise fine.
- " 16. Wind W.N.W., showery and dull.
- " 17. Wind N.E., N.W., showery and cloudy.
- " 18. Wind S.E.S., day fine.
- " 19. Wind S.W., day very fine, slight rain evening.
- " 20. Wind S., S.S.E., showery.
- " 21. Wind W.S.S., violent wind and showers.
- " 22. Wind W., showery.
- April 23. Wind W., day fine, rain evening and night.
- " 24. Wind W., showers and sun all day, heavy rain night.
- " 25. Wind N.E., lowering, heavy rain early morning.
- " 26. Wind S.E., morning rain, day raw and lowering.
- " 27. Wind S.E., rain morning, day lowering, showery until two p.m.
- " 28. Wind E. by S., gloomy.
- " 29. Wind W.S.W., day very fine.
- " 30. Wind W. by S., showery, heavy hailstorm.
- May 1. Wind S.S.W., rain early morning, day lowering.
- " 2. Wind E. by S.W., lowering.
- " 3. Wind W., day very fine.

It will be observed that in this instance the days indicated the weather to

the very end of the moon. Blackthorn winter was not true to itself this year. On the 20th of April I heard the cuckoo for the first time, and on the 1st of May saw several swallows for the first time. Usually I hear the cuckoo from the 15th to the 17th of April, and see the swallows about the 22nd. I then put out verbenas, and when the swallows become plentiful put out my geraniums.—S. B.

HARDINESS OF MANDEVILLEA SUAVEOLENS.—I am informed that at Battle in Sussex the Mandevillea suaveolens not only flowers and flourishes, but ripens its seed on a south wall out of doors. Can you inform me whether this is an exceptional case, and whether it does equally well elsewhere on the southern coast? Our climate here (Wareham, Dorset) is mild, and fuchsias, hydrangeas, all kinds of roses, Exmouth magnolias, and myrtles, escaped with but little injury the past severe winter. Will you also tell me why my orange-trees become yellow and sick, with dead blotches on the leaves? I saw some oranges in Spain and Malta at this season of the year regularly irrigated like an English water meadow; and following that hint, I have had mine kept pretty moist. The Mandevillea flourishes out of doors in the south of France, where the winters are very severe, though the summers are very hot. J. B.

[Sponging with hot water will remove the black fungus on the orange-trees. They probably want more air than they get at present. We shall be glad if some of our readers at Battle will inform us as to the Mandevillea.]

Replies to Queries.

Grass-plot spoiled.—When I came to reside here two years ago, I found a small grass-plot in front of my house in a very neglected condition, full of weeds and coarse grass. A neighbouring nurseryman persuaded me to have it trenched in, and relaid with fine lawn grass-seed. He undertook the job, and procured the seed, and the result is worse grass than before; the habit of which is not to grow upright, but to run along the ground, the stems being thick and white, and the blades of grass of several shades of green. When just mown, the appearance is most objectionable. Can anything be done to remedy this state of things? An answer in the GARDENER'S MAGAZINE, which I take in regularly and value much, would greatly oblige A COUNTRY PARSON.

[This is a sample of the way things are done in hundreds of instances. People pay to be humbugged, and are made sick of gardening through the hideous result of work ill done. Probably the nurseryman employed knows as well as any body how to lay down grass-turf from seed, but, for an extra shilling or two of profit, obtained seed for the purpose that was only fit to sow down rank pasture, or waste ground for the grazing of donkeys and goats. It would have been well if Country Parson had insisted on purchasing the seeds himself, and had sent to some first-rate house for it, such as Messrs. Sutton for example. The result would have been a fine promising sward by this time, needing only a little care and patience to bring it to perfection. But what is to be done now? Mowing is all that can be done through the summer, and the more frequently it is mown, the more will the coarse grasses be checked, and the fine ones encouraged. But if appearances for the present are really of not much consequence, the ground may be again dug over and sown with good seed at once. Grass seed may be sown at almost any time, though the best times are the spring and fall.]

Japanese Seeds.—R. S. W.—The best way to deal with the aged seeds from Japan is to soak them six hours in a solution of nitrate of potash, using a quarter of a pound to a gallon of water; then sow them in pots in a good fuchsia mixture. The pots to be well drained, as it is possible the seeds may be a long time germinating. Place the pots in a sunny frame, lay a saucer or tile over each, and keep them all close shut up. Look at them periodically, and keep them only slightly damp, never wet; do not urge them with heat; and as soon as any seedling plants push through in the pots, remove the covering and transfer the pots to another frame in a shady place.

DIMENSIONS OF SOME FINE OLD TREES.

There are many fine old specimens of trees growing in various parts of Scotland, and some in very isolated positions, which would prove a source of considerable interest to many of your readers, especially those connected with arboriculture, were their size to be taken and sent to you for insertion.

The following is the measurement of some of the largest growing in the parks and pleasure grounds of Gordon Castle, the property of his Grace the Duke of Richmond, taken during the month of February, 1867. Girth at 3 feet from the ground; supposed age of some of the largest and oldest, about 200 years; soil, principally consisting of a dark sandy loam.

The Gardener's Magazine.

SATURDAY, MAY 18, 1867.

A THIRD WINTER HAS SET IN, and those sanguine folks who got their bedding finished in the flush of torrid weather with which the month of May commenced, will in many cases have to plant again or see blanks all the summer, and perhaps find that the check now given the plants will cripple them for the season. We must be always on our guard against deducing general conclusions from isolated instances; but it certainly does appear that the climate of Britain is undergoing a change for the worse, as regards the welfare of tender forms of vegetation, and even of the most common and most useful plants of our gardens and fields. Whether such be the case or not, we have in the present arctic temperature, following close upon an outburst of tropical heat, for which neither animal nor vegetable life was prepared, a new argument added to the many that have been from time to time advanced in these columns, in favour of giving larger encouragement to hardy plants than has been the custom for many years past. It is our duty, and it is assuredly our pleasure, to assist in the gratification of every taste in horticulture, and our readers need not be assured that we are as ready to advise on the cultivation of tender plants as on hardy trees and shrubs and border flowers. Nevertheless, considering the happiness of many of more importance than the gratification of a few, we repeat, while the wind blows from the east, and people who have consigned their great-coats to the store-closet are shivering as if they had been deposited naked on a sheet of ice, that hardy plants are too much neglected, and deserve a considerable share of the energy that is at present bestowed on tender subjects of shortest duration. The public—such of them, at least, as read horticultural literature—experience a sensation when the story of Cliveden is told,—when they hear of Bicton or Dropmore; yet in those splendid gardens there are few subjects employed in the scheme of out-door embellishments but may be termed, without any violation of language, "poor men's plants." We saw, a few weeks since, in the garden of J. B. Saunders, Esq., of Taunton, a collection of variegated aloes that had been wintered safely in an outhouse which is lighted only by side windows, and they were as fresh and healthy as they could have been if kept in the grandest conservatory in the land. These aloes are during summer placed in urns on the garden walk, and thus contribute a classic grace and finish to a beautiful scene, without entailing upon their proprietor any more trouble or expense than the keeping of so many myrtles. In the splendid nursery of Messrs. Lucombe, Pince, and Co., at Exeter, we have lately seen specimens of the golden tipped Thujopsis dolabrata, one of the most elegant trees known, screened with an awning of canvas; and we may see any day anywhere in these islands, if we search out the good gardens, trees, shrubs, herbaceous plants, succulents, ferns, and even palms, that endure all weathers in the open, that fetch their own water, protect their own buds, and train themselves into shape, and that furnish to their possessors perpetual interest and beauty. Many good hardy subjects have indeed been incorporated in the bedding system, and we could not miss from that form of display the pelargoniums, and the tender plants with coloured foliage, which in a few weeks hence will, by judicious grouping, make superb chromatic harmonies for the delight of the eye and the refreshment of the mind. Yet there is need for increased attention to hardy plants, for what is gained in labour and glass, by a reduction of the numbers of tender subjects to make room for them, may be bestowed in a more plentiful production of fruits, and a better system of cropping the kitchen garden. The plants of the stove are for the most part exquisite in beauty, and oftentimes rich in materials for exciting wonder; yet the stove is not the place for general enjoyment, but the cool conservatory and the open garden are the places of assembly for the Republic of horticulture. At the present moment the parterre is in almost every case as bare as a newly-ploughed field. Yet it is the month of May, the "merry month of May," and we look for flowers, for an abundance of flowers; and if we ask where they are, we shall be told to wait a bit. Yes, we will wait; and just when they are in their prime we shall be off to the sea to bathe, or to the stubble to shoot; we shall—that is to say, a large proportion of persons will who live in the midst of elegance (real or hypothetical)—leave the home garden when it is at its highest, and have the satisfaction of hearing afterwards that it was glorious, which is not exactly a glorious satisfaction.

No. 107, NEW SERIES.—VOL. X.

In great places it scarcely matters whether the parterre be gay or dull, for there are pleasant drives, and the American ground is gay, and the grass and the trees are always delightful. But in the gardens that encircle our great towns, MAY FLOWERS are a desideratum, and if people could have them they would value them ten times more than all that belong to June and July, for they would see them, whereas the later flowers are in very many instances not seen, except by the domestics who remain at home on board-wages, and the gardeners, who go in a groove, and are spell-bound by custom without knowing it.

Our wealth in beautiful hardy plants is enormous. Few amongst us, even of those who are richest in knowledge and experience, know anything of its limits. The spring flowers lately seen in Hyde Park by thousands of persons are just an illustration of the case. Mr. Mann, ably backed up by Messrs. Gibbs and Co., has antedated the bedding season, and made a magnificent display with subjects that might be employed in precisely the same manner in every garden in the land. At this moment Mr. Salter, of Hammersmith, has a display of Pyrethrums and Pæonies that no kaleidoscope of summer bedders can surpass. There is no scarcity of subjects, but there is a lack of taste and judgment, or rather taste and judgment have been over-influenced by the éclat with which costly plants of tenderest constitution have been ushered into public notice; and to flower a rare plant, that can be seen only in a heated steam that acts as an ill-timed Turkish bath, costs more in money and time and strength than would suffice to make an entire garden splendid with elegant forms and brilliant colours, and useful with an abundance of good fruits. How many have found the pleasures of gardening so costly that they have given it up, in despair of keeping pace with the demands of fashion? What a pity they could not forget fashion, and think more of the variety, the beauty, the accommodativeness of the vegetable kingdom, which, if allowed, would have sent envoys to their doors and windows, and have blest them in their peaceable homes with elegance and fragrance, and subjects for thought and the means of elegant amusement! Well, it is not the first time we have broached this subject, and it will not, we trust, be the last. At all events, we continue as opportunities occur to direct attention to subjects adapted for British gardens, and that need but small service of money or labour to bring them to perfection. We must leave the public to accept or reject our proposals, but we are at least encouraged to go on, for we see already some good fruit of our labours.

HALL OF ARTS AND SCIENCES.—Her Majesty the Queen will lay the first stone of the New Hall of Arts and Sciences, which is to be erected at South Kensington, on Monday next, the 20th inst. The Queen will leave the Paddington Station of the Great Western Railway attended by a cavalry escort, and, passing through Hyde Park, will arrive at 11-30 o'clock at the site of the hall, opposite the memorial to the Prince Consort in Hyde Park, where a guard of honour will be drawn up and receive Her Majesty with a royal salute. The Prince of Wales, the Earl of Derby, Earl Granville, and the Archbishop of Canterbury, will severally assist in the ceremony of laying the foundation stone; after which His Royal Highness the Prince of Wales and the Provisional Committee will conduct the Queen through the south-east exit from the tent to the east door of the conservatory of the Royal Horticultural Society, where Her Majesty will be received by the Council of that society, and be conducted by the north-western terrace of the gardens to her carriage at the Prince's entrance in Albert Road. The Council of the Society have announced a floral fête for the occasion, when it is expected that the chief exhibitors will be well represented.

EXHIBITION OF TRICOLOR-LEAVED ZONALE PELARGONIUMS.—The exhibition announced by the Royal Horticultural Society will take place, at Kensington, on Tuesday next.

THE REV. MILES JOSEPH BERKELEY, the botanical adviser of the Royal Horticultural Society, the author of "British Fungology," and one of the principal contributors to the *Gardener's Chronicle*, has been assigned a grant from the Civil List Pensions of £100 a year, on account of his eminent services, as a hotanist, to practical horticulture and agriculture. To Lady Harris, widow of Sir William Snow Harris, the author of the "Law of Storms," and the inventor of an improved lightning conductor, a grant of £100 a year has been made; and to Mr. George Cruikshank, the artist, who is now in the sere and yellow leaf, a grant of £95 a year.

THE PARIS EXHIBITION is the subject daily and weekly of letters, descriptions, and eulogies in the pages of our contemporaries. It will be observed, however, that the writers are compelled to travel far and wide to gather a few facts of interest in relation to horticulture; for even now the horticultural part of the exhibition is in a very incomplete state. We learn from our correspondent in Paris that the inner garden is not yet planted, and that the recent cold weather has seriously checked all outdoor operations; but another week may make an immense difference in the state of things.

THE RHODODENDRONS in Hyde Park, especially those lately planted near Rotten Row, are now flowering superbly.

A HOLIDAY IN THE WEST.

PART I.—STOKE NEWINGTON TO TAUNTON.

It is a very odd custom we Londoners follow of making holiday at the fag-end of the summer, when the grass is burnt up and the song-birds have gone away. It is very delightful to indulge in boating and hatching, and hours of dreamy idleness upon the cliffs beside the sea, in the agreeable temperature of sunny September, and we must wait till autumn if the carrying of a gun through the stubble has an important place in our round of rural pleasures. But to see the country in the spring-time, when the London season is at its height, is worth an effort; so, at least, I thought when the primroses began to thicken in my garden borders, and it was said that already a score of nightingales had been heard at the reservoirs in the Lordship Road, and my neighbour Mr. George Spencer's glorious tree of *Pyrus spectabilis* began to show a kind of pink froth all over it, as the forwardest flower-buds acquired colour preparatory to the wondrous burst of glory which that tree makes every year in the month of April. Yes; I thought I would repeat, for the sake of one who has some claims on my consideration, and with perhaps a minute taint of selfishness, such experiences of the West of England in the spring-time as I had made in years gone by. I went down to Poole on some business many years ago, and was there seized with a fit of vagrancy, and forthwith commenced a series of rambles to Bournemouth one way, and to Ringwood, Christchurch, Minster, and Brocklehurst the other; and it happened in the month of April, and when I got into the New Forest, I felt that there was one spot on the big world whereon I should like to live and die—a spot shadowed with old oaks and paved with violets and primroses. There is scarcely a nook in the land that I have not seen in summer, autumn, or winter; but, like most other busy people, it is but little travelling I can do in spring. We talk of the West of England as a sort of elysium for hotanists and horticulturists, but it is impossible to estimate its beauty and capabilities except by visiting it in spring; and so I said to some one whose confidence I enjoy, "We will see the Devonshire dales and the country thereabout in the first leafing of the trees, when the primroses are as thick upon the earth as the stars in heaven." Confidante assented, and on the 19th of April we started from the Waterloo terminus by express train to Yeovil, Somerset, as the first stage of a holiday tour. To see the spring break in the west was the central idea around which revolved our various anticipations of pleasure, but we were longing too to grasp some loving friends by the hand, and enjoy the sweets of communion in a better way than by mere correspondence and occasional hurried meetings at flower-shows and public assemblies. The country was bleak and bare, the ground was sodden and cold; scarcely a fruit-tree except on walls had shown flower; not an oak or elm in the eastern parts had shown the faintest tinge of colour; the dreary winter long drawn out had nipped the tender spring, and the sprouting herb was blighted as it grew, and people were downcast about the crops. I was glad to see before we started that the double furze, which appeared to have been blasted by the winter, was just beginning to push forth a new growth on the lower parts of the main branches, and I said, "We shall see plenty of furze in bloom in a day or two." On the way down we noticed that the furze on the embankments of the South-Western line was as dead to look at as if it had been stacked for fuel; whereas, many a time on the same embankments I have seen it blooming gaily in the month of March. All about Bagshot and Woking the black peat was dreary to look at; few flowers were to be seen, and we had travelled nearly a hundred miles westward ere there were any definite evidences of a milder climate, and then the furze showed here and there a few golden blossoms; farther on it became more gay, and that was the only sign we had from London to Yeovil, on the 19th of April, that towards the west Nature is kinder to man in spring-time than hereabouts.

We got a bad dinner and a good rest at Yeovil, and we saw one pretty sight, and one only, that gave us any interest. Close beside the railway station is a bank facing the highway. On that bank a fine plantation of strawberries, to all appearance Keen's Seedling. Those were just coming into bloom most gaily. Every fourth or fifth plant had two or three flowers open. We left Black Prince at home just showing flower-buds, and they did not flower till May 6th. So we made a mark for Yeovil as a fortnight at least in advance of the northern suburbs of London in respect of strawberries. What else we saw in Yeovil is not worth putting down, except it be a clever chesnut horse on the railway; a horse that understands shunting as well as any civil engineer, and in making up a train acts a good deal on his own account, and with a knowing nod of the head says to the porters, "Leave it all to me."

I like Taunton, for I have some friends there, and they had invited us to eat, drink, and be merry. So to Taunton we sped away, and made amends for a bad dinner by a good supper and a happy rest at "The Laurels," where J. B. Saunders, Esq., and his bonny wife cultivate the herb called heartsease, and understand its value too well to keep it all to themselves. Such generous and considerate hospitality as we experienced at Taunton may not be a proper subject for lengthened remark in a public journal, but I think this page would miss a streak of light that made more beautiful the face of nature, were I to omit mention of the fact that, as your humble servant, seeking knowledge for you while making pleasure for myself and Confidante, Mr. and Mrs. Saunders gave us a welcome equal every way to the brightest benediction of the spring-flowers that now began to spring up in our path. I have your commission to inquire into the ways of nature, and I take license to say that human nature has some goodness in it, and that the kindness that began at Taunton, with unaffected earnestness and gentleness, attended us at every step; so that in truth, as we started to see trees and flowers, we returned with deeper impressions of the western people than of the western vegetation.

On the 20th we had our first out-door feast. Close beside the residence of Mr. Saunders is an old nursery, and far back in the most interesting part of it is the residence of Miss Young, a lady whose taste and knowledge in matters floral and botanical will not be readily matched even amongst public writers on those subjects. We paid a visit to Miss Young, and were received with the most genial cordiality. The big trees surrounding this charming residence were forward in leaf, nightingales sang lustily above our heads and in the adjoining thickets, and the public road through the nursery, by which access to the residence of Miss Young is gained, was gay with the flowers of many trees and shrubs, and with the new growth of many beautiful coniferous trees. Miss Young has not followed the fashionable mode of embellishing the exterior of her residence; there is no parterre, no ribbon-borders; but there is grass-turf, and there are trees, shrubs, and

flowers; on every hand objects of interest and beauty, and the very atmosphere is calm and odorous, and shut in as it were from the general world by walls of verdure. On the turn round from the public to the private road, we were greeted with a spectacle quite novel in its way, yet, like many another spectacle, consisting of most commonplace materials. There were hanks and borders of *Berberis aquifolium* in bloom; not dotted with yellow, as we see them in the eastern parts of England, but presenting solid sheets of the purest gold, the intensity of which, in the sunshine, was heightened by the sprinkling of red leaves every where about the mass. Looking down towards the lawn, through a kind of avenue, a great old rustic basket was to be seen sheeted over with the charming flowers of *Auhrietia purpurea*. Here again the flowers were so thick as to present an unbroken mass of the most delicate purple. We stood some time at a distance enjoying the glitter of gold in the foreground, the rather distant and dreamy blotch of purple, and the general admixture of greenery beyond, while the nightingales, thrushes, and blackbirds, made glorious music to accompany the welcome we received. Before we quitted this place we had experienced as much surprise as pleasure. On the lawn, and in the heds and borders, were numerous interesting objects in addition to fine trees and shrubs. *Arundo donax* has been allowed to make stools eight or ten feet through, and the old canes are ten feet high. For many years this grass has stood out winter and summer without harm, but the winter of 1866-67 has punished it severely, though it is not killed. There were some large stools of what appeared to be *Bambusa gracilis*, with old and withered canes about ten feet high; this was still fresh at the base, and has stood several winters preceding the last, which cut it down and spoiled its beauty. *Lilium giganteum* is here one of the hardiest plants; on the 20th of April plants in the open ground, and that have passed three winters there, had leaves already a foot long, and looking very much indeed like the leaves of *Arum maculatum*, as they peep forth now in the hedgerows. These lilies are planted in good peat; they flower finely, and demand no care at all. *Rhododendrons* were in many instances full of bloom; a fine *Jacksoni*, six feet high, had a grand appearance; and a very old *Arboreum*, rather lean in habit, but handsome nevertheless, was just showing the fine colour of its flowers. In a sheltered nook on the wall of the house *Acacia dealbata* has grown fifteen feet, and for many years has thus flowered profusely, but the last winter nearly destroyed it; it is dead to within a foot or so of the ground, and will be many years getting up again to its former height. It was in full bloom in February last, when the second frost made havoc of it. Close beside it is a white camellia, about ten feet high and six feet through, a splendid mass of dark green glossy foliage. This usually blooms freely, but this year has not flowered at all. On a fine old wall, *Cloth-of-Gold Rose* has had its way for many years, sending out rods of eight or ten feet length, and flowering gorgeously. It is worked on a brier, which is now considerably thicker than any respectable though stout walking-stick. This passed through the terrible frost of January 4, 5, and 6 last, without harm, but began to grow in the warm weather of February, and was cut to pieces by the second frost that came at the end of the month. It is now growing again freely from good breaks near the head of the stock, and probably will nearly fill up its old space before the season closes. Harrison on the same wall is unhurt, and the good old *Noisetete Lamarque*, with several *Teas*, are quite as fresh and vigorous as if they had been protected, though they were as much exposed to the weather as *Cloth-of-Gold*. Before I left the garden I was asked to prescribe for a cork-oak that bleeds profusely all the summer long from an excrescence on the bark. I did not prescribe; but I said if the tree were mine, I should cut off the excrescence, and make a clean edge to the wound, and then hind it up with grafting clay and tarpaulin, in hope of inducing a healthy cicatrization, but I could not recommend this course, for I was not at all sure it would be successful. The tree appears to be none the worse for the discharge, which is probably the result of plethora, but it is unsightly and undesirable. Will any of our readers, who have had to deal with difficulties of this sort, give us a word on the subject drawn from experience? "Experience," I say; but really, with the remembrance of this delightful place still fresh in my mind, I want most of all to get away from experience of the prosy kind, and keep alive the thought of a quiet retreat like this, wealthy everywhere with the gems and jewels of the vegetable kingdom, and all cared for and loved with a sincerity that we boastful horticulturists by profession know nothing at all about. I would rather call to mind, in connection with these scenes, some of the sweetest passages in Keats or Tennyson than speculate on any practical matters. Indeed, I found myself more than once humming half-forgotten verses, and one passage from "Endymion" occurred to me as if written in sheer description of this "happy island," this miniature elysium:—

Paths there were many
Winding through palmy fern, and rushes fenny,
And ivy banks; all leading pleasantly
To a wide lawn, whence one could only see
Stems thronging all around between the swell
Of tuft and slanting branches: who could tell
The freshness of the space of heaven above,
Edged round with dark tree-tops? through which a dove
Would often beat its wings, and often, too,
A little cloud would move across the blue.

By way of a shady walk past a pretty rustic house, we reached the out-door fernery, a most simple but interesting spot. Under the shade of large trees on one side, and a wall on the other, there extends a long bank consisting principally of good peat, supported and faced with blocks of stone. This is so far superior to the "hurrs" from the brick-kiln that Londoners are forced to be content with, that every stone has upon it a beautiful growth of moss or lichen; everything is softened down in outline and colour, and the charm of naturalness—the perfection of a fernery—is one of its principal characteristics. The ferns in this long bank are in a most luxurious condition of growth. Already, on the 20th of April, *Struthiopteris germanica*, the graceful "ostrich-feather" fern, had made fronds eighteen inches in length, and far more than *Osmunda regalis*, in its exquisite grace of form and delicacy of colour, fitted the idea that Do Quincy took from Wordsworth to light up his denunciation of the "insane substruction" that swept *Osmunda* from one of its ancient haunts at Windermere—

Plant lovelier in its own recess
Than Grecian naiad seen at earliest dawn,
Tending her fount, or lady of the lake,
Sole sitting by the shores of old romance.

That *Osmunda regalis* should be here is a matter of course, and here too we found its near relatives, *Osmunda interrupta*, *O. cinnamomea*, and *Onoclea sensibilis*; the last-named fern has long since become quite naturalised at Stoke Newington, and is as hardy as the common poly-

pody. Amongst the lady ferns here were several with rod stems; there were fine tufts of *Cystopteris fragilis*, *Asplenium fontanum*, the rather scarce *Ceterach officinarum*, the delicate *Woodsia ilvensis*, *Scolopendrium* beyond number and in great variety. The father of Miss Young was an enthusiastic collector and cultivator of British *Scolopendriums*; and one of his best seedlings bears the name of Youngii, in commemoration of its raiser. As for the rest of the ferns, I leave you to imagine them, when I say that there were examples of all that a fern-grower would look for as typical and essential to an out-door collection, not omitting the beautiful Cambriom variety of *Polypodium vulgare*, and the stone-loving *Asplenium trichomanes*, *A. virides*, and *A. ruta-muraris*.

Quitting the fernery, we were conducted to a rustic paradise, primarily consisting of dwarf walls and protective hods, where in years gone by there had been formed and kept a superb collection of hardy herbaceous plants; and here they remained still, with the growth and glory of age upon them—a growth and glory that in these plants is equivalent to perpetual youth, for, unlike the tree that may become unsound at the core, these have the power of sempiternal renewal. What do you think of dog's tooth violets and American cowslips thick as pile velvot on a gigantic scale, and forming fields rather than patches? at all events, we saw masses of *Erythronium dens canis* of some twenty yards square in extent, and clumps of *Gentiana acaulis*, dotted over with its gorgeous azure blue bells, of more than a square yard each in extent. *Orobus vernus* had grown into bush-like tufts, and smothered with rosy purple flowers. There too were masses of *Hacquetia epipactis*; the lovely *Dianthus cæsius* and *petræus*; *Corydalis bulbosa*, the simple *Asperula odorata*; myriads of double-flowering *Anemone nemorosa*, a gem of the first water, and with it two formidable rivals in the department of vegetable jewelry, in the shape of *Myosotis sylvatica* and *Myosotis alpestris*, the last named being the choicest perhaps of all the spring flowers native to these climes. A great bed of *Alströméria Van Houttei* filled me with speculations as to the possibilities of the bedding system without the aid of an inch of glass or a single plant of Mrs. Pollock. I cannot hope to give an idea of a thousandth part of the treasures I met with here—such things as *Dielytra spectabilis*, *Alyssum*, *Arabis*, *Iberis*, and *Bellis* I cannot even enumerate, but I must remember *Chrysosplenium oppositifolium*, *Cyclamen coum*, and *C. hederifolium*, *Dielytra eximia*, *Erinus alpinus*, *Hydrocotyle vulgaris*, *Omphalodes verna*, *Phlox alpinus* in variety, *Saponaria cæspitosa*, and *Saxifrage* and *Primulas* past enumeration. Miss Young has a pretty conservatory, which was rich with ferns and flowers; yet these things were all tame to me after the feast in the herbaceous garden, where the growth of years has given to a majority of the finest subjects the distinctive character and true splendour of colour that they have in their undisturbed homes on the moor and the mountain, so different to the little bits that we call plants in ordinary gardens.

S. H.

ELDORADO.

There have been rumours about the north side of London for a year or two past, touching the growth of a nursery where a few trade rules have been set at defiance, and the wants of amateurs are considered in a spirited and conscientious manner. I first heard of it when conversing with my much esteemed friend and neighbour Dr. Denny, on the subject of roses on their own roots, when he told me such roses were being produced in quantity at a place not many miles distant. Again, when making a call on my excellent friend Dr. Brickwell, of Tottenham, I heard of the same place, and saw some roses that had been obtained from thence, and I now began to be curious on the subject. By and bye Mr. Dunbar, who represents Mr. Lynch White in the hot-water business, suggested that I might meet with a few good things if I would visit this place; and so from time to time it has been on my mind, and at last, on a fine day in the early part of last month, I made my way thither, having for companion Dr. Denny, who first called my attention to the claims he thought this nursery had upon my time. So at last we found ourselves in the Hale Farm Nursery, Tottenham, within a furlong or so of the Tottenham Station, on the Great Eastern Railway, chatting on things in general, and plants in particular, with Mr. Ware, the proprietor. I was rather disappointed, nay, to speak the truth, considerably disappointed. I saw no glass, no trees, no display of either work or its results, and I began to regard the Hale Farm Nursery as "all a hum." Close beside the entrance were some narrow borders, which Mr. Ware described as a "winter garden." I thought it weak, almost puerile, though there were some interesting things in it. The borders were divided into diagonal plots with divisional lines of double daisy, polyanthus, double primrose, and in the spaces were clumps of *Iberis*, *alysum*, *saxifrage*, *arabis*, and other useful spring flowers. My idea of a winter garden demands quantities of coniferous trees, hollies, berry-bearing shrubs, and variegated ivies, and then the herbaceous things come in nicely to light it up, both during winter and early spring.

But we pursued our way, becoming interested by degrees, and presently got amongst the houses. Nothing particular for some time, but all neat and tidy, and plenty of stock of what may be collectively termed things of the day. At last we found ourselves amongst the roses, and began, as they say in the game of "hunt the slipper," to "get warm." First a few low-roofed houses, full of *Manetti* roses, all thrifty and promising. Presently we dropped into the midst of some thousands of "own roots." I knew them by their looks, without examining the collar for the scar. All the good sorts of *Perpetuals*, *Bourbons*, and *Chinas*, done in the same way, and with big heads, the pots mostly 54 and 48 size; but one side of a house was occupied with half specimens blooming superbly, and paying their rent very well for cut flowers. We began to talk and criticise in earnest; my friend the Doctor being a thorough rosarian, and Mr. Ware, the cicerone, as eloquent as Cicero on a subject which evidently has a place in his affections apart altogether from business. To give the names of the varieties met with would be only like making elegant extracts from a rose catalogue. But we noticed *Maréchal Niel*, plenty of it; a first-rate rose, apparently, to do on its own roots. Amongst a batch of *Chinas* we picked out some old and almost obsolete kinds, such as *Knights White China*, a very neat-habited *Lawrenceana* sort, which produces myriads of small snow-white flowers in clusters, a counterpart of *Aimée Vibert*, the flowers smaller, and the leaves not glossy; *Saucyer's White*, more robust than *Knights White*, and producing larger flowers in twos and threes.

We saw bedding plants in endless quantities in long pits, the hack wall of the pits being a bank of turf, within which is laid a bed of hot manure, and over that a bed of soil, and last of all the lights, admirably simple, but consuming an immense quantity of stable-dung, which happens to be plentiful on the spot, and costs next to nothing. We found all the new

Alloternantheras, the *Toliantantheras*, the *Amaranthus*, *Colons*, and the rest of the foliage novelties. A few specimen *Lobelias*, *Geraniums*, and *Calceolarias* looked rather promising for exhibition and decorative purposes; but we paid very little heed to such things, for we still wanted to see the herbaceous plants, and began to wonder if they were hidden in one of the furnace chimneys. But we followed our cicerone, and lived in hope. After a walk up a lane and through a gate, and along the side of a ploughed field, and across a piece of meadow, we at last saw before us an almost endless prospect of herbaceous plants grown farm fashion; the Hale Farm had, in fact, changed from a routine of wheat, cabbage, and roots, to one of Sweet Williams, *Polyanthuses*, *Saxifrages*, and *Alyssums*. We found that we had before us twenty acres of such things, and our guide wished us to explore the whole, though the sun was as hot as on a June day. All I could say at first was, "Eureka!" but the Doctor, seeing before him a furlong or so of wallflowers, spoke of *El Dorado*, and remembering that, I put the expression at the head of this notice as a title for it. Yes, Eureka, certainly; I wanted to see herbaceous plants in quantity, and here they were at last. We began with about two acres of Sweet Williams, which were being taken up and sent away in dozens and hundreds. Then we got upon *Alyssum saxatile*, a few thousand plants, with heads bigger and brighter than any of our heads; *Iberis sempervirens*, ditto; Double *Daisies* of fine quality; *Spirea Japonica* enough to make an edging all along the western coast from Land's End to Orkney, where it would do better, doubtless, than on the east coast of this country; yet at Tottenham, which is a cold place, it takes its chance in the open, and flowers as freely as if under glass. So we went on from piece to piece, measuring the acres by the number of rows right and left of this and that, noting especially that pinks and carnations covered extra large spaces. In due time we found our way to the pot plants, and the packing sheds, and the proving border, and we found more to amuse us here than in going over the farm. In order to supply plants at any season without risk, quantities are potted in small pots at the seasons when this may best be done with particular groups of plants, mostly of course in autumn. These potted pieces are set out in batches on beds of cocoa-nut fibre refuse, and they become established in the pots and fit to plant out at any time at the whim of the purchaser. In these beds, therefore, we saw gatherings from the entire collections, and I am bound to say that, though they have not everything (nor has anyone else), there is here one of the most complete and correct and extensive collections of herbaceous plants I have ever yet seen, not forgetting the splendid stock in the cradles at Wellington Road. Close beside this department are two long borders, on which are planted two plants each of every herbaceous plant in the place. As heights and colours are of comparatively small consequence, and facility of finding any particular plant of the utmost importance, this collection is arranged alphabetically, and thus, with the exception of a few difficulties arising out of synonymy of names, it explains itself: if we want to see the species and varieties of *Arabis*, we go to one end of the ground, and if we want *Orobus* we go to the other; and if *Zauchneria californica* is the subject of search, we find it opposite A, for the alphabet goes down one side and up the other.

I shall now make note of a few plants that we took particular notice of, and arrange my notes alphabetically, as we found the plants in the borders. *Alchemilla alpina*, with variegated leaves, an exceedingly pretty plant for a shady place. *Anemone nemorosa plena*, the double white wood anemone, a plant so beautiful that to see it once in a day's march is to be satisfied with life and the constitution of the planet, and forget all the ills that flesh is heir to. *Aristolochia clematis*, a rare and curious British plant, usually regarded as an introduction. *Arundinaria falcata*, the hardy bamboo, which merits attention as one of the best of poor men's plants for the sub-tropical system. *Astilbe rivularis*, such a thing as we may expect to see largely used some day at Battersea—it is very distinct and interesting. *Primula auricula nigra plena*, a black double-flowering auricula, a gem for the choice border. Of show auriculas we saw none; but as we were too early to see them in bloom, we may simply have missed them. *Baptisia Australis*, a scarce but good thing; it is quite tender at Stoke Newington, and we lose it in the winter; but at Tottenham, which is colder and more open, it is quite hardy. *Campannas* in profusion, especially *Barrelieri*, *carpatica*, *garganica*, *glomerata*, *persicifolia*, *pyramidalis*, and *rotundifolia*. *Convallaria majalis*, with striped leaves, one of the most elegant of all known variegated-leaved plants, but scarce, and more likely to become dear than cheap. *Corydalis bulbosa* in great sheets, a superb spring flower. *Delphiniums* and *Dianthus* of many kinds, in plenty of course. *Dielytra eximia*, a good stock; only choice people, who have choice rockeries, care about this very choice but not showy plant. *Dondia (Hacquetia) epipactis*; this is both peculiar and pretty: we have had a tuft of it for ten years past on a raised bank of peat at Stoke Newington, and we consider it one of the best of out-door subjects in the month of March, when its coin-like discs of yellow appear in advance of its leaves, and make little heaps of money on the ground. *Eryngium amethystinum*, so often recommended as a fine plant for the shrubbery border, but which few except botanists appreciate at present, and as a rule we give the botanists all the ugly things, as a punishment for their love of ugly names. *Ranunculus ficaria*, here called *Ficaria ranunculoides* (which is the proper name in books that separate this from *Ranunculus*), in several forms—the common yellow, pure white and double yellow, and double white: after all, I think the common single yellow the best of them, and it is a charming plant when the sun shines on it in March and April. *Gentiana acaulis*, true as steel, and reflecting to the clear firmament its intense deep blue. *Gypsophylla repens*, a most elegant plant for a rockery; every single flower appears to be designed for a fairy's button-hole—if fairies have button-holes; it is in profusion and great variety. *Juncus effusus spiralis*, a very curious and by no means ugly plant; it is, of course, a rush, but its peculiarity is that every one of its cylindrical leaves twists like a corkscrew, and a good plant of it is a study in curves for disciples of Euclid. *Litbospermum fruticosum*, the plant which Mr. Gibson uses so skillfully to bring out the red and gold of Mrs. Pollock geranium; its dark green leaves and dark blue flowers are unique. *Meum athamanticum*, a plant for bold effects, well adapted to afford variety in the parterre. *Muscari botryoides*, the grape hyacinth, rarely seen, yet fit for the grandest garden in the land; *Nepeta violacea*, the neat glaucous-leaved plant that throws up spikes of bluish labiate flowers all the summer, and which Mr. Gordon has used so skillfully to make belts in front of China roses at the Crystal Palace. *Orcis maculata*, a great pit full, all in pots with fat leaves, and promising to flower well. *Primula acaulis*, the common primrose, in great variety, double yellow, double white, double lilac, double crimson—all in plenty; the last a superb variety that will never stay long with any nurseryman.

pity it cannot be propagated from its leaves, for divisions are not fast enough. *Primula elatior*; the *Polyanthus* in great variety, but mostly border sorts, the laced flowers being such as we call "promising;" very few fit for a stage, but all worthy of admiration. *Saxifragas* we must deal with in the lump, save and except that they have a prettily variegated variety of *S. umbrosa*, the London pride. *Schizostylis coccinea*: this has been in the open border at Stoke Newington since first received from Backhouse in 1864 until the close of the year 1866; that is to say, it stood the winters of 1864 and 1865, but succumbed to the severe frost of January, 1867. Mr. Ware says it is quite hardy with him, another interesting exemplification of the difference in the behaviour of the same plant in places only two or three miles distant from each other. Strange to say, what little attention I have paid to it convinces me that its absolute hardiness is a matter of very little consequence, except, of course, that if quite hardy, a stock of it in nursery quarters can be very safely and simply preserved. But as to its use as a flowering plant, its ability to endure severe frost is not a matter for consideration, for it does not bloom (here at least) till the middle of November, and then it blooms freely; but one night of frost is sufficient to spoil all its flowers. The proper way to manage it is to plant it out in spring, and leave it to grow as it pleases, and in October to take it up and pot it, and place it in a cool house to flower during the winter. By this course of procedure it will be valuable at a time when flowers are scarce, and possibly may be one of the best subjects we can find to cut flowers from at Christmas. Sedums are numerous here, but I need only remark on one of them. There is something in the soil of this nursery favourable to those extravagant forms of fasciation to which the term "cocksoomb" is applied. It is a sound loam, fit for wheat, cauliflowers, or forest trees—one of the best of soils; probably unfavourable to the production of variegated sports, but certainly in the production of cocksoombs admirable. The reader will understand I am not now referring to proper cocksoombs, such as the flower-heads of *Celosia*, but to the abnormal consolidation of stems which results in the production of a great frill in place of a multitude of branches. We see many examples of fasciation in the growth of the fir, ash, and willow; some asters are much subject to it, and Lord Wellington hyacinth is as likely to present a compound spike, formed of two spikes united, as to present its spikes *pur et simple*. In looking over the Sedums at the Royal Botanic Gardens lately, I saw several respectable cocksoombs, but I have never anywhere seen such as are to be found in some of the beds of Sedums at the Hale Farm Nurseries. I brought away with me a cocksoomb specimen of *S. virescens* which measured across the head fourteen inches, and consists of five bold frill-like volutions, which are beautifully green, with linear leaves set upon their edges like the teeth of a comb. The stem is a flattened leathery fan-like growth, scarcely able to support the heavy cocksoomb, consequently the plant is always placed so that the head can lean against a clean brick or flower-pot. *Silene alpestris* and *pendula*, two of the choicest of herbaceous plants, in plenty; the fern-like *Thalictrum minus*, looking like *Adiantum cuneatum*, a beautiful weed, to which the O'Shane directed the attention of our readers a year ago; a double *Tormentilla repens*, which of course is good; a very good lot of hardy *Veronicas*, amongst them the pretty *incana*, so well adapted for a sunny rockery, and a variegated form of the common *spicata*; the scarce *Vicia sylvatica*, and all the *Violas*, from *cornuta* downwards (or upwards). The collection of Pinks is good, and so is the collection of *Geraniums*. Thus a bad beginning made a good ending. When the Doctor and self started for home, we were thoroughly tired out with our perambulations, but we had the satisfaction of having seen something, and were well repaid for our journey. We agreed that Ware's nursery was in some sense like one of Scott's or Cooper's novels—dreadfully dry and uninviting at first, but winning by degrees, and at last fascinating, surprising, and delightful.

S. H.

BEDDING GERANIUMS.—No. XXXIX.

Wherever I go amongst the geraniums, I find the old pernicious rule rigidly adhered to, that they must all be judged by their behaviour in beds, which is half equivalent to a condemnation of the broad-petalled race, the pink and prime of all, but the worst generally for out-door bedding. In very few instances yet have the stage varieties—I mean varieties fit for the stage, for many go there that are not fit—met with appreciation; and where a capable cultivator takes in hand a dozen to train for show, it is usually a dozen out of the bedding set; and so we find at exhibitions superb examples of Tom Thumb, Stella, Cybister, Hendersonii, and Punch—varieties quite unsuitable for competitive purposes, and unworthy of the care and time required to make them fit for exhibition. On the shield of Gresset was the motto, *L'aigle d'une maison est un sot dans une autre*—"The eagle of one house is a fool in another;" and a plant that is A 1 with a cultivator who never rises above bedding, will be an object of contempt to a man whose taste has been formed in the midst of auriculas, pansies, and picotees, and who has no more care about bedding than about the fee simple of the planet Jupiter. These are essentially eclectic papers, and we ignore no taste and no purpose that admits of a reasonable vindication. At all events, the bedder has no cause to complain; and if the stage flowers are occasionally thrust upon his attention, it is for his good solely, that he may some day be persuaded to look for nobility and beauty when in respect of colour he is completely satiated. Some sapient (or not sapient) advisers think it a fine thing to accompany their selections with a confession that they know nothing of the broad-petal kinds, or the nose-gays, or the intermediate varieties that bed well and are sometimes good enough for show; but this pen has been dipped in the sap of every member of the great family, and makes no boast of its fitness on the ground of being only half informed or utterly ignorant. Its duty to-day is to select for everybody and for every purpose; to select the best for every taste and every use; to select without prejudice, favour, or affection; and to select on the basis of

knowing—not as some do, by marking off so many from a catalogue, and assuming them to be good. You are now to reverse the purport of the good old French saw, *Le moyen le plus sûr de se consoler de tout ce qui peut arriver, c'est de s'attendre toujours au pire*. You expect no worse, but much better, and throughout the best; and you will prove thereby that in cultivating and collecting zonales, you prepare for contingencies by a process the very opposite to that recommended for the regulation of the feelings. Earl Grosvenor's motto—*Nobilitatis virtus, non stemma, character*—shall govern this day's deeds; no matter whence the thing comes, if it is good, we will have it; and if bad, its destination is limbo. But the "nobility" which is to be characterized by virtue is noblest in the race of noblest flowers; and of these we want just a comprehensive

120 SINGLE-FLOWERING VARIETIES FOR POT CULTURE.

Scarlet and Shaded Scarlet.—Chieftain, Clipper, Herald of Spring, Dr. Lindley, Monsieur Galland, Andrew Marvel, Julius Cæsar, François Chardine, Monsieur G. Nachet, Lord of the Isles, Marquis de Lambertye, Mexico, Monsieur Manganet, Ossian, Prime Minister, Sir Robert Peel, Sobieski, St. George, Valiant, Victor Emmanuel.

Rose and shades of Blue.—Tintoret, Countess of Sefton, Duchesse of Sutherland (nosegay), Duchess (nosegay), Le Peyrouse, Nora, Hector, Notable, President, Beauty of Meldoise, Cecilia, Fairy Queen, Forester, Gloire des Roses, Lucius, Poet Laureate, Provost, Shirley Hibberd, Rubens.

Pink and Peach.—Beauté de Suresnes, Boule d'Asperides (nosegay), Fascination, Hibberd's May Queen, Lady Martin, Rose Rendatler (nosegay), Pink Beauty, Pink Perfection, Reserve, Serena, Mrs. W. Paul.

Salmon and shades of Red.—St. Fiacre, Archevêque de Paris, Bel Demonio, Charles Rouillard, Christine de Dergine, Coquette de Rueil, Emile Licaun, Enamel, Excellent, Highgate Rival, John Veitch, Madame Chardine, Marie Drouart, Princess, Rosamond, Victoria de Puebla, Wood Nymph, H. W. Longfellow.

Painted.—Ary Zang, Berthe Porte, Havilah, La Prophète, Madame Calcot, Eugénie Mezard (syn. Madame Rudersdorf), Mons. Rendatler, Amelina Grisan, Bride, Christabel, Diadem, Madame Gueffier, Madame Werle, Monsieur Gueffier, Rosebud, The Clown.

White.—White Perfection, Virgo Marie, Comtesse de Cambourn, Lara, Madame Barillet, Marie Mezard, Snowball.

Variegated leaves, whitish or creamy predominating.—Rosetta, Bijou Improved, Alma, Flower of Spring, Italia Unità, Countess of Warwick, Kenilworth, Mrs. P. J. Perry, Scutellatum, Silver Chain, Stella variegata, The Bouquet, Venus, The Countess.

Variegated leaves, yellow or sulphur predominating.—Golden Chain, Reine d'Or, Luna, Goldfinch, Mrs. Pollock, Sceptre d'Or, Sunset, Yellow Belt, Sunrise, Bronze Shield.

Double.—Triomphe de Gergoviat, Ranunculæflora, Gloire de Nancy, Gloire de Corbeny.

If smaller selections are wanted, there can be none better than those at page 109 of the "Garden Oracle" for 1867, where will be found groups of fifty and twelve, and a selection of the best in all classes for 1867. But I will try once more, and make a list of

A very select Twenty-four.—Dr. Lindley, Clipper, Herald of Spring, Lustre, M. Galland, Beauté de Suresnes, Pink Perfection, Forester, Chieftain, Gloire de Corbeny, Triomphe de Gergoviat, Eugénie Mezard, Madame Werle, Virgo Marie, White Perfection, Amelina Grisan, Andrew Marvel, Poet Laureate, Flower of Spring, Italia Unità, Rosetta, Mrs. Pollock, Luna, Golden Cerise Unique.

The foregoing are practical lists, for all the varieties are obtainable; and there is not one named that need cost more than half-a-crown, while the majority may be obtained at an average of 9d. each. A five-pound-note will buy one plant each of the whole collection, and, if trading were in my way, I should like to sell them at that rate as fast as I could propagate them. If more expensive kinds are wanted—as they should be—the names and descriptions of the best novelties will be found in Nos. XXXVII, and XXXVIII. We shall have to deal with Tricolors shortly *in extenso*, and I am waiting till I can sit down in my garden snuggerly and leisurely review them in a proper light, and in their best condition; meanwhile, as this is a buying time, I shall say that *Lucy Grieve will grow* if people will have patience with it. It has not grown hitherto, for much the same reason that Baron Munchausen's horse could not get full of water after the affair of the portcullis. The horse left his latter half behind in the enemies' breeches (Shade of Hood, forgive me!), and as fast as the water was sucked up by the beast, it ran out at the other end, as see the history, Chapter XVII. If you keep cutting the tops off Lucy Grieve, it is impossible it should grow to a respectable shape and size; every cutting removed makes the plant so much less in size, and also checks its root-action. There is such a clamour for cuttings, and such a hunger to increase it, even where they have enough already, that the plant has no chance. But give

it a chance; do not cut it, do not force it; be patient, and I repeat **IT WILL GROW.** *Sophia Cusack* is, to my eye, the best of the series for a specimen, and when seen in an elevated position, so that the eye glances over the discs of its leaves, it gives a hint of the next step in the production of coloured leaves, for it is then seen to contain a considerable amount of *blue* in its colouring. The present generation will see *blue* in these leaves: it is there already in plenty; the task for the breeder is to separate it. *Beauty of Guestwick* I have seen lately, and have no doubt at all of its fitness for a specimen. Smith's *Sir Joseph Paxton* will be famous, and some others of Smith's. One of the best old florists living told me the other day, that he went to Dulwich last summer to see the house of geraniums there, and he finished by remarking, "I wouldn't have missed the sight for twenty pounds." *Sunset* makes a grand specimen. Witness, in proof of the assertion, in spite of its wiry habit, one in the tricolour house at Wellington Road; it is perfect, and proud enough is the cultivator, Moxon, of his triumph. In that way *Sophia Dumaresque* is a genuine advance, and quite worth the 31s. 6d. at which, with *Lucy Griev* and *Sophia Cusack*, it will be sent out this season. Saltmarsh's *Meteor* is glorious, and threatens to supersede Mrs. Pollock, and Henderson's *Lady Cullum* will no doubt make as good a bedder as it is already seen to make a fine pot-plant.

Now let us turn to the bedders, and lump the round and nosegay flowers together; but we will distinguish the latter with the letter N.

A SELECTION OF NINETY GERANIUMS FOR BEDDING.

Scarlet.—Attraction or Perfection, Editor, Baron Ricasoli (N), Boule de Feu (the true variety is quite different to Attraction, Perfection, &c.), Kate Anderson, Comte Zamoyksi, Cybister (N), Flambeau, Eleanor, M. Thiers, Mars, Minimum Nosegay (N), Multiflora Nosegay (N).

Crimson and Purple Shaded.—Banneret (N), Black Dwarf (N), Miss Parfitt (N), Stella (N), St. George, Imperial Crimson, Christine, Beauté de Suresne, Excellent, Lady Martin, Madame Barré, Model Nosegay (N), Pink Perfection, Wiltshire Lass, Minnie, Model Nosegay (N).

Rose and Rosy Purple.—Countess of Sefton, Duchess, Lady Middleton, Picturatum, Purple Nosegay (N), Purple Unique, Titian, Cliveden Rose (N), Fairy Queen, Hector, Lucius, Lord Palmerston.

Orange and Orange Scarlet.—Indian Yellow (N), Harkaway, Orange Nosegay (N), Harry Hieover (N), Rival Stella (N), Hieover's Pet.

Pink.—Christine, Madame Barré, Pink Beauty, Christine Nosegay (N).

Salmon.—H. W. Longfellow, St. Fiacre, Emile Licau, Enamel, Jean Valjean, Minstrel (N), Salmon Nosegay (N).

Painted.—Amelina Grisan, Eugénie Mezard, Souvenir de Nancy, The Clown.

White.—Purity, Galanthiflora, Snowball, Virgo Marie.

Blush.—Madame Vaucher, M. Gueffier, Rosebud, Madame Gueffier.

Variegated Leaves, White or Creamy.—Alma, Annie, Bijou, Flower of Spring, Flower of the Day, Jane, Lady Plymouth, Manglesii (first-rate for edgings), Mrs. Lennox, Queen of Queens, Shottesham Pet, Silver Chain, Harcourt's St. Clair, Variegated Nosegay (this looks as if the leaves of Bijou and the flowers of Christine had made a match and eloped, and their first child partook of the complexions of both parents), Italia Unità, Oriana.

Variegated Leaves, Yellow or Sulphur colour predominating.—Golden Fleece, Annie Williams, Golden Chain, Goldfinch, Luna, Sceptre d'Or, Yellow Belt, Mrs. Pollock.

Here again for a small collection I must refer to the "Garden Oracle," where a dozen of each class is given, and in each case a dozen that cannot be beaten. But we have not yet done with the subject of this day's labours. In seeking out sorts for this and that purpose, we inevitably meet with sorts that are not fit for any purpose, yet are too good or too peculiar to be ignored. Hence we want a class for nondescripts, which we may as well call

OUTSIDERS.

Glowworm.—A fine nosegay, the colours of the flowers crimson-shaded purple or magenta. When at its best beautiful, but too shy for a bed. It is superb for the plunging system, because it can be brought forward when full of colour, and removed when the colour wanes.

Lady Colum (Beaton).—This is a pretty well known nosegay, of dwarf habit. It is not fair to place it in a list of bedders intended for general purposes, because it is peculiar, and on some soils scarcely blooms at all, and to show its best qualities requires a warm season. But it is one of those peculiar and beautiful varieties that every practitioner of bedding should try his hand with, and there is no better way than to make an odd bed, and thereby judge of its future uses. The colour is put in the cata-

logues as "magenta;" it is rather lilac-pink, soft, delicate, fresh, original, and beautiful.

Premier (Beaton).—In the way of *Lady Colum*, but more inclining to rose colour, and with foliage more striking.

Magenta (Beaton).—This is a superbly coloured but shy nosegay. To bed it may be to spoil a scheme, to be without it is to be in the dark. Remember, in respect of bits of wealth like this, the Horatian rule, *Imperat aut servit collecta pecunia cuique*,—if we do not govern our goods, they will govern us. I saw a grand piece of planting humbugged by *Magenta Nosegay* last year; where there should have been a bold band of purplish lake to balance a band of crimson, there was a band of green with purple dots. The man who made that mistake is one of the ablest colourists in the country, and one of the most ingenious and experienced judges of the capabilities of plants adapted for bedding. In this case he exemplified the maxim of Rochefoucault, *Il est plus aisé d'être sage pour les autres, que pour soi-même.*

Eugénie Mezard.—This is also an insider, as seen above. It is so good in the painted series when grown as a pot plant, that many would fear to make a bed of it. But it is a first-rate bedder, and in the full sun loses its white margin, and becomes a clear salmon. In the event of cold wet weather it does not wear well.

Peach Nosegay is a lovely subject for delicate shading; make an odd bed of it, if you do not know it already.

Rose Rendaller makes a grand bed on its own merits, but is too robust and peculiar to be easily worked into a scheme. As a bedder, generally speaking, it can only be handled by a master.

Rosetta, in the silver-leaved section, is in its place above as a first-rate bedder. I place it here in order to say that it is one of the most elegant examples of colouring we have, and fit only for the most refined work in the parterre. The leaves are abundantly creamy; the flowers are soft lilac pink. It is one of those that should be planted, if possible, for both flowers and leaves; but if used for leaves only, will be found A 1. It requires a good climate, and is not fit for the London gardens.

Venus (Lennox) is a creamy-leaved variety, with peculiar and beautiful rosy pink flowers. With *Rosetta* it would associate superbly for chaste painting.

Beauty of Oulton is grand in a sunny position, and better without flowers than with them to show its rich brown zone.

Golden Harkaway is scarcely inferior to *Golden Chain*, though many degrees hardier.

Brilliantissima is comparatively unknown. It leaves the old *Brilliant* far behind. Let those who love lightning, volcanic fires, burning prairies, glaring furnaces, and the flashes that result from a blow on the ossa nasi, look after it. If any difficulty, inquire of Messrs. E. G. Henderson. When I know it to be cheap, I shall put it in the list of bedding scarlets; but while ignorant of its price, I make no risk, else how could I aver that 120 sorts could be obtained for the average amount paid for a vote at Yarmouth?

MINIATURES.

The following are of the smallest growth, and all are good:—Saltmarsh's *Little Treasure*; this puts *Baron Hugel* out of court; it is equal to *Attraction* in style, but the plant never grows larger than a penny loaf, even when bread is at 9d. Carter's *Christabel* is a miniature *Christine*, admirably suited for edgings; it might have been called "Pink Cushion," but we will keep that name for future use. *Multiflora* is a pigmy nosegay: the flowers scarlet, and plenty of them. *Minimum Nosegay* is of the smallest size; a good scarlet. *Harkaway* makes a good orange edging. *Harry Hieover* will do for a match to *Harkaway*. *Spread Eagle* is scarcely so small as to be called a miniature, yet it is so dwarf as to be well adapted for marginal lines, and it is a first-rate orange scarlet. *Dandy* does not always please, for it is a quiet gray, and never shows up bright and sharp; but for small work, where strong colouring is not wanted, it has its value still, though it is steadily going out of cultivation. *Manglesii* makes a lovely edging, but few people do it properly. At the Crystal Palace it is largely and skilfully employed. All the ivy-leaved race make good edgings if carefully trained down. The *Golden-edged Ivy-leaf* is a beauty for edging; and the scarlet-flowered, lilac-flowered, and white-flowered ivy-leaved make good beds and pleasing lines.

S. H.

CHEAP CONSERVATORIES.

When talking with our Editor a few days ago, he showed me some sketches of various kinds which have been made for the purpose of providing engravings for the Magazine, and amongst them I observed one taken in the nursery of Mr. Burley, of Bayswater, in which there are represented some tree-ferns, dracænas, and other such plants. I said I could see in that sketch the suggestion for some useful words to the lovers of beauty, who I find are most prodigal of their means for the gratification of taste, but not always so successful as I would wish them to be in their results. My friend told me at once to put down my thoughts in English as I best might,

and I am now doing so, my object being to promote the love of the noblest forms of the vegetable kingdom, and at the same time show that much money may be saved from the customary outlay on the houses that are built for enjoyment.

I, of course, can have no objection to the erection in gardens of costly plant-houses, with elaborate wooden stages within side, and the valuable plants all placed so that the best views we obtain in walking round are of the sides of the pots, the diagonals of the timber, and the under-sides of the leaves of the plants. But, in behalf of the thousands who dwell near the great towns, I wish to say that none of these things are necessary. There are thousands of tasteful persons who would enjoy the collection and cultivation of choice plants, but are terrified at what they hear the cost to be, and abandon the promptings of a pure taste through fear of being led into extravagancies beyond their means. To such I will remark that, in the first place, a very large proportion of the finest plants of the whole world can be preserved in health in all the temperate parts of Europe, as far north certainly as the 45th parallel of latitude, if kept safe from frost. I have heard of some tree-ferns that have been planted out several years in some part of Ireland; and about them I shall not only inquire but travel; but I call to mind the

they have instead a stuffy stove that few people can endure the heat of, and that costs a great sum of money, and gives little real pleasure to the members of the household. But Mr. Williams's house is of a far more expensive kind than such as I mean. Let us mark out our house, and adopt the ridge and furrow with light iron pillars (or iron gas-pipes) for supports, and use a light framework with glass to the ground. To do this well, consulting utility only, with a little ornament on the façade to prevent a mean appearance, and we may cover a given space of ground at one-half, or perhaps one-third, the amount usually paid for elaborate structures, that are not a whit more useful than the simple sort of thing that is in my mind. Why, if I were to set up a nursery, I should build houses that would do their work well at a fourth part of the cost usually incurred in private gardens. Instead of glass to the ground, we might have raised banks of earth to form rockeries outside, and sloping borders inside. Within these banks I would put square piers of rubble and cement, or in a stone district blocks of stone, or in a wood district butts of big trees; and on such supports the house should rest, and they would receive the thrust; and, in the case of a tenant building on another man's ground, give the tenant the right to move the house

TREE-FERNS AT MR. BURLEY'S NURSERY, BAYSWATER.

report, because I can believe it, and it exemplifies my meaning, that plants of the highest nobility are not all in need of costly hot-houses when imported into these cool climates. I am no advocate for planting out subjects that require to be protected with mats, or that are pretty sure to be destroyed by frost; for even if such things live in the midst of hardships, they have not their proper beauty. There has been much folly of this sort; it does harm not only by the waste of money, but it checks the taste for pure horticulture. But give the shelter of glass, and there is little more required for the preservation of plants of the most eminent renown. Then as to the kind of shelter. Why indulge in a grand lofty structure, when one of the most simple kind will do? My idea, for a man of taste who is not also a man of fortune, is to build a *large house*, tall enough for the plants, and to employ either wood or iron, and to arrange the mechanism so that it will hold together during a storm, and to have heat enough to keep out frost, and no more. Mr. B. S. Williams has built a noble house at Holloway, and it is furnished with just such plants as are most worthy of being seen in every private garden. That is a large house; it is heated most admirably by means of Jones's Terminal Boiler; it is at all times cool, never subjected to frost, and is in truth a garden under glass. Just such a house might be in many a garden where

at the expiration of his tenancy. To compensate for the absence of solid walls and heavy timbers and deep foundations, I would employ cross tie-bars, which cost nothing and afford almost indescribable strength; and the lightness of the structure would be in favour of its long lasting, for the only strain it would be subject to would be during gales of wind. As to the ventilation, I would have shutters at the ground line, and under the line of the ridge; with such I would cause the whole body of air to move, and to move constantly, and in summer they might all be open day and night.

In the inside the arrangements must depend upon the size of the house; the larger the house the better, as in a large house plants with bold handsome foliage grow best and look best, and, in the event of severe frost, the larger the house the less rapidly does the air within it cool down to the freezing-point. As to stages, I would have none. Observing, in the sketch of Mr. Burley's house, that the tree-ferns stand on the floor, gave rise to my remark that this is the kind of house for the man of taste; for while saving the enormous cost of interior woodwork, he gains the advantage of seeing his plants in such a way as to enjoy all their beauty; and too often it is a painful task to look at the plants at all; it makes one's eyes ache, and there is danger with putting the head back so much that it might fall off. Well, suppose I have room, I would make gravel

walks eight feet wide, and beds between, with sometimes a raised bank, to vary the surface and for the special display of flowers. Many such things as Camollias, Acacias, various Climbers, Sikkim Rhododendrons, and Japanese shrubs, might be planted out, but others that it would be thought best to keep in pots might be plunged to the rim, so that we should see them situated as in nature, and should literally walk about amongst trees and flowers in this our winter (and summer, and all-the-year-round) garden. To be sure, this is not shown in the sketch; for Mr. Burley sends his plants to exhibitions, and to embellish at festivals, and has them also for sale. But we see them on the ground, as I wish to see them in places where they are now up in the sky, and we ought to be as the angels in Jacob's dream, going up and down ladders to see the beauty of the world. A great space filled with plants such as we cannot see in the open garden is a grand spectacle, if well done; but very different is it when the plants are mounted on a tall platform, and the path is wide enough only for a walking-stick to pass along, and the eye can only distinctly perceive the pipes for heating, the edges and under-sides of the woodwork, and the exhibition of pots above, while outside there is a huge stokery and an ugly chimney. I have just said that I would have gravel walks; but I know that in early spring, if the gravel happened to get wet, it would be very cold, and I should like such a house to be always attractive to ladies. Let this be considered, then, that gravel is sometimes cold to the feet; but cheap tiles are warm and always dry, comparatively speaking; and the best way to put down tiles is to bed them in sand; they never move, and the sand quickly takes from them superfluous water.

As to the plants, there is no end to the possible variety; the noble Dicksonias give us forms of the grandest type, it is impossible to surpass them. To grow them needs no more skill than to manage any greenhouse fern; in fact, their only peculiarities are that they like shade and moisture. Then the Camellia, which is grown at so much cost and, I will say, anxiously wishing not to offend the English gardeners, with very much of fuss, what does it want more than a good loam to grow in, a rather dark position, at least, to be not in a strong glare of light, a humid atmosphere, and protection from frost. Those are all its requirements. Then the tender Rhododendrons, the wondrous Nuttallii, the chaste Edgeworthii, and others of equal beauty, that will scarcely live in the open garden, except in some peculiarly sheltered spots,—a cool house and a shaded position are the utmost of their requisites. Shall I say again that the brilliant Azalea, that succeeds the camellia in the spring, when a garden under glass is most precious; here is the place for it; keep out the frost, and as regards temperature you have done enough. That glorious tree the Araucaria excelsa, a tree which surpasses in beauty any average hundred trees that can be named, needs just such a house as I propose and nothing more. Ferns, Lilies, Dracænas, Dasyliirions, Aloes, Yuccas, Ericas, Palms, Vallotas—no; I dare not enumerate the families that would furnish beautiful and sublime forms of vegetation to such a house; and as for colour, I have mentioned a few showy subjects already, and I would add that any number commensurate with the space at command of bulbs could be flowered in the spring, and the zonale pelargoniums would take up the pleasing tale when bulbs, camellias, and azaleas had become unattractive; and thus we should reach the autumn safely, and then would look for chrysanthemums to continue the story that should never all be told. In such a house the shadows alone would be a treat; I think there is much joy to be found in shadows. I sit at the window on fine evenings now, and observe the shadows in my landlord's garden; they fall from the old picturesque fruit-trees athwart the smooth green grass like as if they had a life of their own, and they move round and round as if afraid of the sun, yet dreading his setting; for his sleep is their death. Ah, how it minds me of the theology of the Brahmans! who say that when Brahma wakes, the universe is peopled with orbs that swarm with life; but when Brahma sleeps, creation passes away; *it is not*. Better is the faith we follow; for it teaches the truth that Jehovah, who is our God, never slumbers nor sleeps, and the creation He has fashioned will never pass away: He maketh not to destroy, but to bless, and to bring forth praise to His most worthy name.

To draw up a list of plants adapted for such a house would be no difficult matter; the difficulty would be to keep it down to moderate dimensions, because the range for choice of selection is almost boundless. The best of all known climbers would be suitable, from Tacsonia Van Volkemii to the renowned Lapageria rosea. And when the amateur had exhausted the list (impossible) of cool plants, he could go the stove from June to September, and obtain some more. So if the cheap house had not perpetual beauty, it would not be the fault of the house, but of the master. For a last word, I shall say that in soft plants much money is expended that would buy hard ones. The difference between them, in respect of purchase, would be that the hard ones would improve from year to year, and be as it were everlasting, but the soft ones would want to be renewed annually; there is in fact no end to the expense of soft plants, if

good collections are kept. But I have no prejudices; I love everything that the earth produces, and I wish in my day and generation to assist, as far as my few talents permit, my brethren of the great human family to share that love with me, and enjoy it more even than I do myself, if that be possible. KARL PROSPER.

THE FLOWER GARDEN AND THE BEDDING ARRANGEMENTS.

The planting-out of the various bedding plants has now commenced in earnest, especially in the southern counties, the month of May having made her *début*, accompanied by such remarkably fine weather as to induce many of our horticultural friends to push on the work of bedding with more haste than is usually adopted at this early period of the season; and should the weather continue to favour the operations during the remaining part of the month, why those who have seized the earlier opportunities will have gained a considerable advance in growth ere the flowering season has begun; yet, in the ordinary course of things, we may expect some adverse weather. I can remember some very chilly nights, with some severe nipping frosts, to have occurred towards the latter end of this month; and experience has taught me to be very cautious about exposing my bedding plants too early. To those who have not completed their bedding, and are contemplating its various arrangements, such as the harmonizing of colours in the distribution of their different varieties of plants, perhaps a few ideas or so in relation thereto may be useful, especially to such as entertain doubts as to the effectual working of some of their plans. In considering the many modes now employed in contributing to the embellishment of the flower garden, we must, in our endeavours to add to its effect, be guided by the scenery and the growth of the various kinds of vegetation that surround us. Although our public gardens and parks afford us some bright examples of elegant planting, yet, before we attempt to copy or otherwise imitate them, we must not forget the scale on which they are executed, because breadth and length in planting considerably heighten the effect of even the commonest kinds of plants. If our grounds are somewhat limited, then is our difficulty increased as to the fulfilment of our tastes and desires; but, on the other hand, if we have sufficient scope, then to some extent, our gratification may be more easily secured, because we are thus enabled to carry out some of the designs and prominent features of successful planting we may have previously observed in our rambles abroad. This, then, brings me to my subject, the consideration of which is not so much intended for those who possess large establishments, but more especially for those whose means of display are somewhat contracted in regard to space. In referring to the harmonizing or contrasting of colours, so as to impart a refined tone to the garden, we must say that, although there are laws which teach us to blend them in harmony—and certainly such teachings are of great value—yet, independent of these, there must prevail a taste with the individual, for a man who has no taste of his own cannot apply principles. There must also be knowledge derived from practical acquaintance with the various shades of colours and habits of the numerous classes of plants that are used for bedding. I would offer, as a general advice, to avoid where the space is small the planting of many beds of one kind of plants, particularly if they are high-coloured self-flowers, as yellow calceolarias, &c., because they are calculated to detract from the interest which should be bestowed on the other kinds. An excess of strong colours is antagonistic to that mellow but refined softness which ought to be more or less perceptible in all floral arrangements. The aim of the planter or designer should be to find out the shades or colours which are most pleasing to the eye, when associated with the objects that overshadow or surround them, or come in contact with them; and this is one of the reasons why we should not be mere copyists, or, in other words, we should not merely borrow the ideas which are adopted in other gardens for our sole guidance.

There are many reasons to be assigned why the order of planting or bedding should be changed in small private gardens, as compared with public or large private grounds. Now some persons have a great objection to planting beds on what may be called the mixed system, that is, of having borders or bands of two or more kinds of plants of opposite colours planted in the same bed, believing that it only tends to confuse, instead of affording a pleasurable gratification to the mind of the beholder. There may be logic in this argument; but, with all that, circumstances entirely alter plans that are even stamped with the approval of the many. Some maintain that beds which are entirely planted with self-colours produce the best effect; and most certainly they do, if the extent and position of the grounds are favourable to such; for it is only where the grounds are large and the bedding extensive that we would advise its general adoption; but where space is limited, there would the mixed or banded system of bedding look best, for by it we are enabled to develop the character and beauties of a greater number of species and varieties

than we could otherwise do, and thus enhance the interest of the garden; but with it there is more after-care devolving on the cultivator, that he may preserve throughout the season the distinctness of the outlines, so as to clearly define their separate shades of colour. With this, as with everything else in general practice, that we may approach perfection, it is well for us always to be provided with a memorandum book, and note not only that which is satisfactory, but all that admits of improvement, with suggestions for the following year's planting.

Having said something respecting the planting of beds, we will now offer some observations on the ribbon style, which has been somewhat modified by the introduction within the last few years of what is termed "panel" gardening; that is, nothing more than plots at equal distances being planted so as to represent beds, without the customary walk and edgings, the ribbon planting being connected and continued at each end. Nothing, perhaps, for grandeur of effect can surpass a well-arranged border planted ribbon fashion, but what contributes most to realise this effect is Length, for the longer it is the more imposing it is. A straight but even surface of border is another essential. I have seen a good many borders planted in this style, but nothing, to my way of thinking, has exceeded the beauty of two borders I saw planted, about 120 feet in length, and from 7 to 8 feet in width, each side of a gravel walk. They presented a perfect level, save a slight curve towards the end. They were planted thus:—

LEFT-HAND BORDER.	RIGHT-HAND BORDER.
A back row of young laurels.	Back row, mixed dahlias.
Ageratum.	Ageratum.
Perilla Nankinensis.	Perilla Nankinensis.
Yellow calceolaria.	Yellow calceolaria.
Scarlet geranium.	Scarlet geranium.
Purple King verbena.	Purple King verbena.
Edging of variegated mint.	Edging of variegated mint.

JOHN F. M'ELROY.

THE ORNAMENTAL GOURDS.

Amongst the curiosities of horticulture that have sprung into favour during the last few years, not the least important are the Ornamental Gourds. Amongst the seekers of what is curious—professional as well as amateur cultivators—these have found many admirers. Nor is this at all surprising when we consider their claims to notice in the way of curious forms and colours, to say nothing of the beautiful markings of some of the varieties. It is now six years since I first began to cultivate them in any number, during which time I have learnt some of their peculiar requirements to grow them successfully, and I am tempted to give the readers of these pages the benefit of my experience in these few notes, hoping they may be useful to the few, if not to the many. In the first place, I have found that they rarely do well when raised in heat and nursed under glass, as when so treated it takes them a long while to recover the exposure to the elements, even when carefully hardened off; they do better when sown in the natural soil where they are to stand, as then they suffer no check by removal, and throughout the season plants so raised are more healthy, and make altogether a more vigorous growth than those raised in heat under glass. Not that they dislike bottom-heat, because, when the position will admit of it, I take out a couple of barrow-loads of soil and fill up the space with two barrow-loads of rather dry stable-dung, to which I add one barrow of short grass from the lawn. This is well mixed and trod firmly into the place from whence the soil was removed. Upon this I place six inches of soil, and then sow the seed. In a few days a mild bottom-heat is generated by the grass, and the young plants soon show themselves, and grow with a freshness and vigour that would surprise the advocates for planting out from pots; there are no yellow or sickly leaves, and no flagging after planting, which necessarily follows the planting-out system.

There are very few of the Continental varieties but will endure full exposure to a southern aspect better than they can endure a more shady one. This is especially the case with the more beautifully marked varieties, such as the Prince of Wales, as their colours are brought out much better, and consequently they make a richer effect. A strong rich soil is not so essential for the more ornamental varieties as a rather light open one, as their roots delight to ramble and ramify in an open porous position. Therefore, to confine them in a given space, say in a square hole two or three feet over, is not the best system that can be adopted to secure success, as if their roots have free scope to search out food some few feet round about, their fruitfulness and vigour will be greatly increased.

I must not be understood to mean that they will do well in any poor soil or position, because the whole structure and habit of the plants speak to the contrary, as being vigorous growing subjects, they of necessity require a good deal of nourishment; and although such may be given them in the form of liquid manure, I have found they never thrive so well with that as when their roots can

collect sufficient for their purpose, by rambling amongst any half decayed organic matter that may be collected into a heap in every well ordered garden. A few very weak doses of sewage water will do good when the roots are confined for space, but it should not be repeated at every watering. Ordinary rain-water or, what is better, soap-suds may be applied liberally during a continual drought.

C.

Calendar.

WORK FOR WEEK COMMENCING MAY 18.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—High culture should be aimed at now with all vegetable crops, frequent stirrings between the rows with the hoe to keep down weeds, and abundant supplies of water and liquid manure. It is hardly possible to give too much water, and in exposed situations, and on thin soils grass mowings should be used as a mulch to keep the ground moist, but should be examined occasionally to guard against its becoming a harbour for slugs. Put sticks to rows of peas as soon as they require it; well bank up those that are forward. Thin parsnips and carrots to eight inches apart, and go on transplanting from seed-beds as fast as the plants are large enough to handle, leaving the smallest to get stronger before moving them. Choose showery weather, if possible, for transplanting, or else give shade for a few days, and gentle watering. Flat-hoe potatoes, and draw but little earth to their stems: the old method of moulding them up has proved to be of no benefit at all, rather an injury, as the heat of the sun cannot have too ready an access to the roots. Thin out celery, and make up small beds for the plants on very rich hard ground. Trenches should now be made for celery, and six inches of rotten dung forked into the bottom of each. A dull or showery day should be chosen to put out the plants, and plenty of water given during dry weather. Look to seed-beds, and transplant; well hoe and clear the ground as may be necessary. The use of liquid manure and frequent stirring of the ground between growing crops will hasten and improve the growth of all things.

Sow beans and peas for succession, savoy for late crop; cabbage, broccoli, kale, beet-root, kidney-beans, both runners and dwarfs, lettuces, spinach, turnips, cucumbers, and marrows may now be sown in the open ground for a late supply.

CELERY.—In pricking out, choose a hard bottom for the bed, on which lay four inches of rotten dung, and two inches of light rich soil. Handle the plants tenderly, water lightly and regularly, and keep the lights over till they look brisk and growing. They will lift from such a bed with vigorous roots, and at the first planting out choose the forwardest plants, and let the others remain for the next set of trenches.

POTATOES.—Hoe between the rows as soon as the plants appear, and hoe frequently irrespective of weeds and moulding up. If planted deep enough in the first instance, we consider further moulding an injury to them.

RIDGE CUCUMBERS AND MARROWS.—Marrows, cucumbers, and melons may still be sown; the latter require the most heat, and cannot be well fruited unless they can enjoy a temperature of 70° to 80°, and five more degrees of bottom-heat. Pumpkins and gourds of all kinds, as well as Stockwood, Southgate, and short prickly cucumbers, may be grown to great perfection in the open air, by starting the seeds in a gentle heat, and when the plants have formed their rough leaves turning them out on a bed of dung or loam well enriched, and giving them the protection of hand-glasses for the first fortnight. Those who have no hand-glasses should protect them every night till June, by turning over each plant a flower-pot with the hole stopped. Ridge cucumbers bear well and give little trouble. Cucumbers and gourds should not be stopped, but allowed to ramble as they will, either on the ground or a rough trellis. They should have abundance of manure water in dry weather, and the fruit cut as fast as it is ready, as, if one is left to ripen, the vines cease to be prolific.

BEEF of the first sowing to be thinned to one foot apart as soon as large enough. Time enough now to sow for a crop of moderate-sized roots to store for winter.

BROCCOLI.—Sow both early and late sorts, not forgetting Snow's Winter White.

CAPSICUMS AND TOMATOES may be turned out on warm borders towards the end of the month, but there will be nothing gained by over-haste. Tomatoes planted against hot walls should be covered every night till the first week in June.

Flower Garden.

CHRYSANTHEMUMS lately struck to be potted off, and have a little bottom-heat for a week or ten days, and after that to be plunged in beds of coal ashes or cocoa-nut waste. Cuttings put in now will make nice shrubby plants by autumn, if well treated. When shifted to 60's, let them have a firm loamy soil, plenty of turf and well-rotted dung, abundance of water overhead, as well as at the root, and exposure to all weathers. Chrysanthemums make nice plants for ordinary purposes from May cuttings, and better without than with bottom-heat.

DAHLIAS should never go out till quite strong, unless to be protected every night with inverted flower-pots, each pot to be covered with a mat. Dahlias should be potted in rich stuff, to ensure strong plants before planting out, and be gradually hardened. Cuttings put in now will root in a few days, so that sorts of which the stock is small may soon be secured.

EDONOS newly formed to be watered in dry weather. Saxifraga Icelandica makes a beautiful bright green edging for a close line.

HYACINTHS to be kept green until they have completed their growth. If carelessly turned out from pots and glasses, the hot sun and dry winds will all but kill them. They really want kindness, and it is best to turn them out with great care in a bed of rich sandy soil in a frame, and keep them rather close until the foliage begins to turn yellow; then expose them to the full sun to encourage ripening, but do not touch the bulbs for at least a fortnight after the leaves have quite perished. By that time the bulbs will be ripe, and may be cleaned and stored away.

FLOWER GARDEN.—Successional sowings should be made of all hardy annuals that may be required to succeed those sown in March; and

tender kinds, such as asters, zinnias, &c., may now be sown in the open ground. This is a good time to sow hardy and half-hardy perennials of all kinds, to get strong plants for winter, either to remain out, or have the protection of a frame, or to take up and pot for early blooming in the greenhouse. Lovers of the Chinese primula should sow now for the next spring. Late planted roses should have plenty of water, and the surface mulched, and similar treatment given to hollyhocks and chrysanthemums put out last month. Carnations and picotees should be staked without delay, and their shoots thinned. Part and plant polyanthus and primroses that have done blooming, and give them a rich loam and a shady aspect. Where it is intended to have new gravel, it would be advisable to defer it till the beds are filled, and the whole garden acquiring its full summer gaiety; a coating of fresh gravel then will add much to its fresh and bright appearance. Roll and mow grass turf frequently, to promote a fine close growth. Any watering of plants in the open ground should be done in the morning now, as the nights are often very cold.

APHIS BRUSII.—The soft brushes sold for the removal of aphides are of great service where a few plants are affected, and it is worth while to fumigate; and it obviates that too common practice of crushing the vermin on the plants with the fingers. Pinks and auriculas are better cleansed by the brush than by any other method.

CIRCUMPOSITION is a method of propagating without removing the shoot to be rooted. An incision is first made in the bark, say of a rose-shoot. When that has healed, the shoot is drawn through a pot, which is fixed by some support according to the requirements of the case. The pot is then filled with light soil, and kept moist, and in about three weeks is full of roots. The shoot is then separated from the parent plant by cutting it through close under the pot. Of course when the pot is placed some of the leaves and buds must be removed where the shoot is to be covered with soil. This is the best time to propagate by this method, and it is of great value to get plants on their own roots which it is difficult to strike by other ordinary processes.

ANNUALS are held in light estimation because people do not really cultivate them. Thin out the patches and top the branching kinds, and they will bloom so vigorously as to be altogether unlike the crowded spindling things on which people vent their abuse. Quick-flowering annuals sown in shady places at the end of the month, or early in June, will come into flower for succession to those that are exhausted, and prove of great service.

BEDDING PLANTS to be kept growing till of sufficient size for hardening off, and fresh cuttings put in of those of which the stocks are short. Sorts that are in a fit state for turning out to be carefully hardened first, as any severe and sudden check will put them back tremendously. Place them in cold pits first, and shade from midday sun, and cover up at night. By degrees, let them have full exposure, and to be left uncovered night and day before turning out. Plants purchased from nurseries generally require careful hardening, owing to their having been pushed rather fast. In selecting at nurseries, prefer plants from open frames if you can get them. If dahlias are turned out early, they must be protected at night with inverted flower-pots with the holes stopped, and by bell-glasses during the day, should the weather be wet and cold. The 15th is quite early enough to begin to turn out dahlias. Put the stakes to them at once. Take cuttings of everything that is wanted to bloom late in the season, and for next year's stock. Verbenas and petunias struck now in a brisk heat will bloom well at the end of July.

AURICULAS.—Pick off the seed-vessels as fast as the plants go out of flower, but do not cut down the flower-stalk. When done blooming, place the pot on a pavement of tiles out of doors, and let them have air and showers. But very heavy showers must be kept off by means of a spare light or a few boards, to be removed as soon as the storm is over. Any infested with fly, smoke well before turning out.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Plums and pears, and indeed all bush and pyramid fruits, will want pinching in to the third or fourth leaf from the base. Where large crops of fruit are set, thin severely, but not all at once, as the more fruit the poorer will its quality be. Give strawberries plenty of water. If raspberries have not been mulched, give them at once a top-dressing of half-rotten dung. Do not dig it in.

Greenhouse and Conservatory.

GREENHOUSE.—Hard-wooded plants will want plenty of air, and specimen plants in flower must have shade. Allow nothing to form seed, unless seed be specially desired. Cut back all kinds of shrubs that are out of shape, and keep them rather close afterwards, to get good breaks, so as to bring them into decent shape, and get the wood well ripened for next year's bloom. Where plants are crowded, many may be removed to frames, so as to allow of a freer circulation of air. Shift, stop, and tie out all soft-wooded plants that are advancing in growth; but if required to bloom shortly, they must not be disturbed, merely kept in shape, and have plenty of water and free ventilation. Continue to strike bedding stock for late blooming. Fuchsias, geraniums, verbenas, and petunias make beautiful specimens for pot-blooming in the autumn, if struck now and kept regularly stopped till July. They should not have a high temperature, fuchsias especially, which like shade and moisture. Cinerarias done blooming should be cut down and planted in rich soil, in a cold frame, to furnish offsets for potting. Camellias and azaleas that have made their young shoots should have a little more ventilation to prepare them to go in the open air next month to ripen their wood. All growing plants, and especially hard-wooded ones, must be regularly stopped, and have plenty of air, to ensure a sturdy short-jointed growth, and tiffany, or the canvas called "strainer," put up inside the house, where moderate shading may be necessary. Pelargoniums out of bloom to be cut in, and allowed to break before repotting them, and the syringe and fumigator kept in use as may be necessary, to destroy red-spider and green-fly. Fire-heat should be dispensed with as much as possible, preparatory to clearing and cleaning out the house.

CONSERVATORY will soon want embellishing with plants in flower, as many of the climbers and other large subjects will be past their best, and tree-pæonies, forced roses, deutzias, &c., will be gone. Celosia pyramidalis, stocks, balsams, and globe amaranthus should be pushed forward; fuchsias and pelargoniums will of course be coming on well, and herbaceous calceolarias ought now to be making a grand show. It is necessary to have plenty of these things, because of the demand for cut flowers at the season when lawn parties are in vogue, and a good supply will allow of frequent

changes in the conservatory, where, if anywhere, variety and change are charming. Permanent occupants of the conservatory will now be growing with vigour, and must have plenty of water. Use shading sufficient to prevent scorching, but do not treat the sunshine as an enemy.

AZALEAS must now be growing freely, and the best place for them is a viney or pit. It is not good for them to be near the glass, even if it is shaded; much better to be far from the glass without shade. Weak manure-water will greatly benefit those that are well established in their pots, and are not to be shifted this year; but any lately shifted should not have a drop of anything but pure soft water. A damp atmosphere is eminently favourable to the new growth. Any just done blooming to have the trusses removed, ill-placed shoots cut back, and then be shut up.

CAMELLIAS that were put into heat to start them into growth must now be cooled down preparatory to hardening off. At the same time lessen considerably the supply of water. It would be better in many gardens no doubt if camellias were never put out of doors, for the cultivator who is hard pressed for work is apt to leave them to take care of themselves, and as one part of that abandonment consists in giving them no water, it follows that they are sometimes quite dried up, and the newly-formed flower-buds receive a shock which causes them to fall when they ought to flower. The fact is, the most important season in the management of the camellia is now before us, namely, the season when the growth is ripening and the flower-buds are forming.

EPACRIS.—All the early-flowering kinds will now require a shift, and it should be done before the new growth has proceeded far. They should first be pruned into shape. It is not necessary to break the ball, but the crocks and pieces of charcoal must be removed. Put them in pots two sizes larger than they are in now, using peat of a kind that can be broken up without soiling the fingers, and with it a good proportion of silver-sand. Put a few nodules of charcoal over the crocks, and pot firm. Place them in a pit or cool house when potted, and give a little shade, and keep them close. When growing freely, nip out the points of the shoots to promote a bushy habit. The best place for epacris all summer is in a pit on a bed of cocoa-nut fibre. They must never be exposed to the full blaze of the summer sun, but must not be constantly shaded.

ERICAS must be removed to cold pits, unless they are grouped with New Holland plants in a very light airy house built especially for such plants. Those that are growing freely require abundance of water. Our own native heaths grow to an immense stature in bogs, though they live and flower finely on dry gravelly slopes where not a drop of water can lodge. There is not a single species of Cape heath but will derive benefit from abundance of water in the growing season. In like manner, they enjoy air and light, and close houses or pits are death to them.

CUTTINGS of all the bedders should be taken as far as they can be spared, either by bushy plants, or to stop leaders of those that ought to be bushy. Always allow the plants cut from to break before disturbing them at the root, as one check is sufficient at a time. Hardy spring flowering plants may be propagated from cuttings as soon as they have flowered, and a stock of Alyssum, Arabis, double Walls, &c., got up very quickly and with less trouble than by sowing seeds.

FUCHSIAS for exhibition to have frequent and regular attention, the growth to be symmetrical, plants never to lack moisture; not much sun. Bedding fuchsias are best from cuttings of the season, the old stools to be thrown away. Make the beds deep and rich with plenty of old dung and good leaf-mould.

GERANIUMS struck now will make fine plants to bloom from July to November. Cuttings of geraniums should now be inserted singly in thumb-pots, so as to be ready for shifting to 60's without injury to the roots as soon as large enough.

BALSAMS AND COCKSCOMBES for exhibition to have a good shift in rich light soil, and a little extra heat to promote new roots. They must have abundance of water to prevent green-fly, which is sure to attack them if they are starved. As they fill their pots with roots, give manure-water, but not till the roots touch the sides of the pots. Balsams required very large must have the bloom-buds nipped out as fast as they show, and the points of the shoots stopped, to cause them to break and form dense bushes.

CINERARIAS to have a little sandy compost placed around the stool, into which the suckers will throw roots, so that when taken off they may be put into thumbs singly at once, which is a gain of time and strength to the plants. As they are cut down and moulded, place them in a cold frame, and shade from midday sun.

RESERVE PLANTS.—There will be a certain number of Geraniums, Verbenas, Calceolarias, &c., left after the beds are filled, and these may be grown into specimens for keeping the houses gay, and to make good any gaps that occur in the planting. A few cuttings of geraniums of all the sorts in stock should be taken now and potted singly in thumbs, which they will soon fill with roots in a warm house, and form stocky plants for autumn bloom. Odds-and-ends of plant stock for which there is no immediate use should be placed out fully exposed to the weather, and the best material to stand the pots on is the cocoa-nut refuse, in which no insects will harbour. It is always sweet and moist.

Stove and Orchid House.

ORCHID HOUSE.—In the Indian and Mexican houses abundant moisture and a liberal temperature may be allowed. By far the greater number of the most valued species derive their chief subsistence from the atmosphere, hence frequent sprinkling of the paths and stages should be practised. Where there are large plants needing abundance of atmospheric moisture, the walls and tables near them should be drenched frequently, and the tanks should be kept full. This treatment will be most needed by Saccolabiums, Vandas, Phalenopsis, Dendrobiums, and Aerides, which make little progress unless liberally treated. Manage, however, to get the houses rather dry once a day by means of ventilation, so as by shutting-up and watering to imitate the natural deposition of dew of the jungles, from which these plants come. When syringing, use a very fine rose to cause the water to fall in a shower. Plants on blocks must be dipped twice a day. Plants recently potted must be kept alive chiefly by means of atmospheric moisture, until established, when they may have dipping and syringing as required. In any case of accident to a plant, cut away at once any bruised leaves. Plants newly received from abroad place in damp moss in a warm place until they begin to grow, then pot or block them, and give very little water until they have taken to their stations. These should always have the warmest part of the house and plenty of atmospheric moisture. Plants in flower to be kept cool, and in a dry atmosphere. To prepare them for removal to the dwelling-room, where they are

always welcome, remove them first to the cool end of the stove, and let them go nearly dry, having only enough water to keep the roots moderately moist. Water should never be thrown upon the blooms of orchids, and as far as possible bees and other insects should not be allowed access to them, as in case of the blossoms being fertilized they soon wither. Temperature of Indian house 65° to 70° by night, 75° to 85° by day. During sunny days the temperature may be allowed to rise to 90°, if the air is saturated with moisture, without harm. We must repeat the advice given last month, to use shading, which may now be kept up for the season.

WINTER FLOWERS.—This is the best time to propagate a supply of Cannas, Begonias, Euphorbias, Justicias, Poinsettias, and other quick-growing soft-wooded plants, for display during winter. Specimen plants to be assisted with manure-water, and the shoots to be stopped of all shrubby and branching kinds. Justicias especially should be freely grown now, to get the wood well ripened for a good bloom at the turn of the year.

STOVE CLIMBERS now want plenty of room, and liberal culture; the syringe will do wonders to keep down vermin. Average temperature for pines 75° at night, 85° to 90° by day; for general collections, 65° to 70° at night, and 75° to 85° by day.

Forcing Pit.

PINES.—Suckers should be removed as soon as they make their appearance, except so far as they may be required for stock. Queens never produce good fruit unless the suckers are removed early. Young pines, for winter fruiting, should be in a rather light soil, to prevent excess of moisture from stagnating about them. Pines for fruiting in autumn to have a bottom-heat of 90° by day, and 75° by night, with abundance of moisture. Plants throwing up suckers to have abundant watering and every necessary attention. In too many instances they are neglected at this stage of their growth, and the consequence is that stock has to be raised from poor weak suckers instead of the strongest that the plants can make.

VINES that have their roots in inside borders should be liberally supplied with water, and the shoots should be tied in in good time. Vines in pots will require frequent supplies of liquid manure, and stopping of laterals must be attended to, to regulate the growth. Red-spider must be kept in check by the use of sulphur, and the best method of using it is to paint the pipes with a mixture of sulphur, lime, soot, and water. Go over the bunches occasionally, and thin them regularly, to promote their beauty and the size of the berries.

MELONS just planted must be kept close and warm till the roots get to work, and then a short-jointed growth should be encouraged by moderate ventilation and abundance of light.

CUCUMBERS IN FRAMES will require plenty of air and a brisk bottom-heat. Re-line the beds where necessary. Train and thin the shoots. After lining, give plenty of water round the insides of the frames. Sow or strike cuttings for succession. Ridge cucumbers to be planted out under hand-lights or trenches two feet and a half wide and one foot deep, filled with dung twice round to a foot above the level. The dung should not be soiled over for a few days after making the bed.

PEACHES ripening to have as much air night and day as can be given; if the lights are off, all the better. Keep the atmosphere pretty dry, but the border must be moist while the trees are still growing. As soon as the trees show that they have made sufficient growth, assist them to ripen the wood by letting the border get rather dry, and the more the sun roasts them the better. We have frequently advised the clothing of the lower part of leggy trees by inserting grafts. Where that was neglected at the proper time, the object may be accomplished by inserting buds, which will now take directly.

ON THE NUTRITIVE CONSTITUENTS OF WATER.

By PROFESSOR SCHULZ-SCHULTZENSTEIN.

(From the Journal of the Royal Horticultural Society.)

(Continued from p. 202.)

In my treatise "On the Discovery of the Real Mode of Nutrition in Plants," I have thoroughly explained the operation of gypsum, and illustrated it by experiments. It rests simply on the supply of sulphuric acid and the assimilation of sulphur, whereby the oxygen is carried off by respiration. The sulphate of lime in the gypsum is not immediately appropriated by plants; but the abundant oxalic acid in leguminous plants sets the sulphuric acid free, since the oxalic acid, in consequence of its greater affinity for lime, combines with it to form oxalate of lime. In the older parts of the plant, therefore, as a residuum of this process, large quantities of crystallized oxalate of lime are found, which often fill the whole tissue.

There was aware that pure attenuated sulphuric acid sprinkled on plants has the same effect as gypsum, which is easily explained by the fact that gypsum itself operates by means of the elimination of sulphuric acid by means of oxalic acid. Gypsum, therefore, has no effect on plants like grasses, which contain little or no oxalic acid. This old experience is explicable only in this manner. Exactly in the same way as gypsum, phosphate of lime is decomposed by oxalic acid, and the phosphoric acid assimilated, and exactly in the same way all other salts of lime, and amongst them the humate.

Were Liebig's theory true, that gypsum acts only by the fixation of ammonia, the effect on all plants must be the same, and similar to that of animal manure; in this case gypsum must be as profitable a manure to meadows, rye and wheat crops, as to clover and peas, which is, however, notoriously contrary to truth.

The Liebigian theory of patent manures, which rests on erroneous views of the nutrition of plants by means of carbonate of ammonia, and according to which a mixture of salts of potash and soda with lime and magnesia is prepared with carbonate of ammonia, has not been confirmed by its practical use, and the sanguine hopes which were entertained by many in its favour have been sadly deceived. Prince Dimitrii Dalgoroucki has in consequence lost a whole crop of *mangel-wurzel* in the south of Russia. Curiously enough the majority have not given up the theory of the nourishment of plants by carbonic acid and carbonate of ammonia, and especially that of their nutrition by means of the air, though Liebig's manure has proved a failure.

The theoretic grounds which have been brought forward since the time of Van Helmont, De Geer, and Bonnet against nutrition from the soil, and in favour of the sustenance of plants from the air, have been constantly repeated, to the prejudice of science and practical cultivation, without any thorough refutation. They deserve therefore to be recapitulated and illustrated. Van Helmont, in 1651, instituted an experiment of planting a willow,

of 5 lbs. weight, in a pot filled with 200 lbs. of dried earth, and watered this in a covered pot with river-water only. At the expiration of five years, the willow weighed 169 lbs. 3 ozs., and the soil after being dried 198 lbs.; so that the earth had lost 2 lbs., while the tree, without reckoning the fallen leaves, had gained 164 lbs. On this it was concluded that nutrition takes place by the decomposition of water and from the air, without a knowledge of the large quantity of *humus* contained in the river-water, which was more than enough to supply the whole of the increase. Similar experiments were made by Eller (1752) and Duhamel (1748), and admit of the same explanation, the error involved in them being inevitable so long as the quantity of *humus* in spring and river water was imperfectly known. Bonnet sowed in a wet sponge and moss oats and barley, and obtained a few miserable plants, a circumstance which admits of explanation if it is considered that all dead organic substances are changed into *humus* by contact with the roots of plants. De Geer endeavoured to raise plants on strips of paper, cotton-wool, and sawdust; he produced only a few shoots, but regarded these as the product of nutrition from the air, although it does not appear why, in this case, as gigantic plants should not be developed as in good soil. He left out of sight the partial decomposition of the organic matrix; the experiments moreover were imperfect, inasmuch as it was not observed that in new sawdust plants not only would not grow, but soon perished.

Very recently the theory of the aerial nourishment of plants has received some support from the communications of the English traveller Darwin, which, it may be assumed, were brought forward without a proper knowledge of the circumstances by Liebig, Schleiden, &c. Darwin had before him especially the cultivation of tropical countries—the culture of rice, sugarcane, bananas, coffee, yams, and mandioca, which is conducted by mere irrigation without any animal manure. Darwin has himself visited but few tropical countries where such a cultivation takes place without manure, and has observed even this very imperfectly. He instances the cultivation of maize in Peru and Chili, which is conducted in barren river-sand, without remembering that it is irrigated by rich humous water from the mountains, and in consequence receives the richest possible nutriment. Further, he concludes from the cultivation of the oil-palm in Guinea, in the moist sand of the coast, that nourishment takes place from the air. Schleiden, Liebig, &c. have spoken with amazement of the fact that 33,000,000 lbs. of palm-oil are exported every year from Guinea, which contains some 24,000,000 lbs. of carbon, without any animal-dung from which it might arise, and conclude therefore that dung and soil supply no carbon. Had they known that a single moderate-sized German river—the Elbe, for instance, at Magdeburg—yields daily 1798 cwt., or yearly 64,728,000 lbs. of humous extract, which contains above 40,000,000 lbs. of carbon, their amazement at an exportation of 24,000,000 lbs. from the whole of Guinea would be much diminished, especially since the waters of tropical lands are far richer in diffused *humus* than those of colder districts. Darwin and Tschichatschew ("Travels through the Pampas," 1844) estimate that a proportionate quantity of carbon is afforded, without any manure, by the luxuriant growth of the herbage in the Pampas of Buenos Ayres, from which countless herds of wild oxen and horses are supported—simply from the skins of these animals, which answer to a weight of 6,000,000 lbs., which therefore must arise from the carbonic acid of the air and the decomposition of water. When, however, we consider how rich the water of the soil is in *humus*, we shall see that the alleged amount of organic matter is nothing in comparison with the carbon which flows yearly into the sea with the *humus* of the Amazon and Orinoco, into which rivers pour whose waters are almost black, and which is constantly renewed from the soil. According to Darwin's theory, the culture of palms in our stoves could certainly not be accomplished.

To arrive at a correct judgment of the cultivation of plants without manure in warm climates, great distinctions must be made of different lands and localities. We may reckon as countries in which, with few exceptions, cultivation is carried on by mere irrigation without the use of manure,—in Asia, Arabia, Persia, Turkistan, Chiwa, Bochara, the East Indies, Siam, Cochinchina, China, Japan, Malacca, Birma, Ceylon, Java, New Holland, Tasmania, and the South-Sea Islands; in Africa, the Cape, Guinea, Madagascar, Senegal, Morocco, Egypt, Abyssinia, Madeira; in America, the Brazils, Mexico, Chili, Southern North America, and a part of Canada. In these different countries, however, in spite of the irrigation, the soil is not equally favourable to cultivation, but the nature of the ground is as important an element of fruitfulness as with us. It is a very great error, therefore, when Schleiden, Liebig, &c., decide from the very imperfect and one-sided observations of Darwin on the perfect indifference of tropical soils as regards the success of cultivation.

As regards the nature of the soil in Hindustan, especially Malabar and Coromandel, we have the excellent observations of Franc. Hamilton (Buchanan, "Journey," ii. pp. 504-857, as also of Christie (Jameson's "New Edinb. Journ." 1829, April-Oct.). Good and bad classes of soil are generally distinguished there, as in Germany, with reference to their constitution, colour, aridity and moisture. The richest black soil is the "cotton-ground," which covers the whole basin of the table-land of Darwar, in the Deccan, in beds which are often from 20-30 feet thick, and are frequently deeply cut by the tributaries of the Kistna. This soil becomes extraordinarily hot in dry weather, and affects the plants by its temperature. It has arisen from the decomposition of the trap rock, which extends far and wide through the Deccan, and derives its dark colour from root-fibres and animal and vegetable *débris*. This soil produces from year to year without manure, which is not surprising, from its great depth, inasmuch as its thinnest stratum is at least 3 feet.

Cotton, however, can be cultivated on this soil only every third year. It is sown at the end of the rainy season in August and September; it vegetates in a week, and grows in the dry season, with indigo, spring-wheat, and tobacco. The harvest is from January to March.

A second sowing takes place at the end of May, or the beginning of June, at the commencement of the rainy season, as soon as the ground is soft, of barley, cleusine, and sesamum, which are capable of enduring considerable moisture.

The third summer's sowing takes place at the end of June or the beginning of July, during the height of the monsoon rain, especially of leguminous plants, as beans, lentils, *Dolichos Lablab*, *D. Catiang*, *D. tranquebaricus*, and *Cytisus Cajan*, besides sorghum and rice. The mountain-rice, according to Christie, is manured.

Even the sandy bottoms on the coast, where the coco-palms are cultivated, may be divided into good and bad. In good moist soil the coco grows so fast that it bears fruit in eight years, and in twelve has attained its full diameter, lasting to eighty. The poorer the soil, the later the palm is in coming to perfection, and the shorter the duration. In good soil each tree produces monthly twenty, or yearly 100 nuts, while in bad soil it yields only from

two to six. It bears blossoms every month in good soil only, and yields palm-juice the whole year; in poorer bottoms the produce of wine is small and at the most continues for six months only.

All this is quite incompatible with the theory of air-nutrition. We have information with respect to the soil of the island of Java, from Raffles in his "History of Java," and from Junghuhn. According to the fertility, they distinguish: 1. Rich black mould in the course of rivers (Tana ladin), such as occurs between Batavia and Weltowreden, with a rich vegetation of banana, mango, tamarind, custard apple, and coffee. The richer in humus, the lighter and looser the soil, the more it is adapted for coffee-plantation. 2. Tana linchad is a pure white clay with sand, which in plains fitted for irrigation yields a single rice-harvest. 3. Tana pasir is the alluvial soil in the maritime district—the delta-land.

The nature of the soil in the North of China has been described by Fortuno ("Wanderings in the Northern Provinces of China," London, 1847). The cotton-ground is here a rich but never boggy loam, though it is manured with canal-mud. Tea succeeds only on very fruitful rich sandy loam. Since the agriculturo here does not depend on breeding cattle, the use of green manure is general. In the rice-fields a *Trifolium* and *Coronilla* are cultivated for manure, which is of use in the case of rice, which is poor in nitrogenous matter, but does not answer for wheat.

The sugar-cane attains a height of from 10-16 feet in Guiana, in the flooded levels of the Essequibo; while in the hungry limestone it is but from 6-10 feet high. We see, then, what enormous errors require rectification, as regards the accounts of the fertility even of the most barren soil within the tropics.

One of the most important observations is that even the richest soil, when it is tilled year after year without any manure, is at last completely exhausted, which would be quite impossible if nourishment were derived from the air. The richest sugar-plantations in Guiana, on the Essequibo, endure only forty years. The unmanured coffee-plantations of Java last about the same time. According to Junghuhn, those on the terraces of Tjisonari, planted in 1804, had grown quite wild in 1846,* and yielded very little fruit; whereas recent plantations, made since 1836, were so luxuriant that not a sunbeam could reach the earth. The richest soil of Texas is exhausted in twenty years; the poorer in from eight to ten. This exhaustion depends, not upon the exhaustion of ammonia, as asserted by Liebig and Boussingault, since, according to the observations of Baumhauer and Krocke, the contents of the soil in ammonia without any manure are far larger than could be the case were it exhausted by the growing plants; besides, ammonia, according to the observations of Kuhlmann, is naturally reproduced in the soil itself. The exhaustion of the soil depends rather on the exhaustion of the humus; and from this arises the possibility of restoring its fertility by means of mouldering humific dung. But where no manure is used, fertility is restored after many years by the growth and decomposition of hardy weeds which are supported by the moist innutritious soil. We find, according to Junghuhn, in Sumatra and Java abandoned plantations turning into Allang-fields (tracts overrun with species of *Saccharum*), while the inhabitants avail themselves of new plots of forest-ground. The effect of fallowing is nothing more than that of dressing ground with green weeds, which live on the water of the soil (which is poor in nutritious matter), and then form humus by their decomposition. The process which favours the nourishment of plants is the process of decomposition.

The assumption of Liebig, in favour of the carbonic-acid theory, that every acre of land, whether it be meadow or field, produces on an average 20 cwt. of dry vegetable matter, either as hay, wood, clover, corn, or tubers, rests upon entire ignorance of the experience of horticulture and agriculture, and is as wrong as the imperfect observations of Darwin, according to which tropical plants grow from pure sand by means of the air. Such notions can only lead to error in practice, and act injuriously on cultivation if it is conducted in accordance with such theories. All experiments on the fertility or sterility of soils, on the restoration of fertility by means of different kinds of manure, on the different produce of woods, meadows, fields, and gardens, are useless in the face of such assumptions; we may as well give up speaking of fruitful and barren land. The reckonings of pounds and hundred-weights of carbon, nitrogen, and hydrogen in plants, which proceed on such fundamentally erroneous prejudices, are altogether worthless, and lead only to perplexity in things of every-day experience. The carbonic-acid theory has long retarded and confused the physiology of plants, and separated science from practice, as its theories are practically useless. Such errors and such ignorance must be expressly and clearly exposed, in order first to get rid of them, and then to make progress possible to something better.

The fertility of the soil depends upon its capability of furnishing nutritive dissolvable substances, with which the surface-water may be impregnated. The humus must be capable of being dissolved. The insoluble condition of ulmin in peat does not allow water to extract from its nutritive matter; therefore peat-moss, though moist, is sterile without contact with the air through desiccation. The soluble humous constituents of the soil must be difficult of solution, in order to their entering into the water in a very weak proportion, since plants can receive nourishment in very weak solutions only. This is a very important point, that plants can endure no concentrated food. The richer the soil, the greater must be the quantity of moisture to attenuate properly the nutritive liquid. This is the reason why strong manure is so injurious in a dry soil. Inquiries into the injury of plants from concentrated manure, suggested the idea to Ingenbousz that dung does not enter principally into plants in the form of a solution, but must be converted into a gaseous form by decomposition, and that carbonic acid and nitrogen are the peculiar nutritive elements of plants,—a theory which cannot be made to agree with the practice of manuring.

A consequence of the reception of very attenuated nutriment is the great need of water, and the great quantity which plants consume. The strong evaporation of plants, on which we have the old statistical experiments of Hales, Duhamel, and Bonnet, as well as the more recent ones of Schübler, corresponds with this large quantity of water. A surface of water covered with *Pistia Stratiotes*, according to Isert, gives off six times as much as that which is free. The negroes in Guinea, as Forster relates, place this plant in pots of water at the doors of their houses to cool the air. Schübler found that a square foot of meadow-ground, covered with grass, gave off twice as much evaporation as 40-45 cubic inches of water. The evaporation of a moderately large potato-plant may be reckoned at from 1½-2lbs. daily; so that when full-grown it consumes mostly about 60lbs. of water. It appears that no physical drying takes place, from the fact that,

as the plant in autumn withers and decays, the evaporation diminishes in an extraordinary degree.

The very attenuated condition of the humous nutritive matter in surface-water makes an easy transmission of it possible. There exist in surface-water, besides the humous extract, perhumate of lime and ammonia, humates containing nitrogen, erenic acid and its modifications, geic acid, humic acid, ulmic acid. Instead of these acids there appear in the raw sap, after imbibition, gallic acid, acetic acid, tartaric acid, malic acid,—also, instead of humous extract, on the thickening of the raw sap, as for example in birch, a gum which assumes the colour of a humic brown. These new acids are slight modifications of the proportionate ingredients of humic acid; and it may be regarded as a proof that they arise from those, that the colourless sap containing these acids is very easily reduced through boiling to humus, of which it assumes the brown tint. Carbonic acid and carbonate of ammonia are never found in raw sap. The further alterations are these: the change of mucilage (dextrino) in the sap into grape and cane sugar, as also the separation, by respiration, of oxygen from the above-mentioned vegetable acids, which are the only sources of the oxygen eliminated from plants, whereby the plant assimilates not only carbon, as in the carbonic-acid theory, but at the same time the hydrogen and nitrogen of the base of the acids to form gum, sugar, wax, fatty matter, starch, and wood. The easy transformation of humus and of the bituminous constituents of the soil into gum and sugar, appears from the extraordinary tendency of both, especially in black soil, to form sugar in the cultivation of beet-sugar and wine. The dark bituminous lime in the Crimea produces a rich development of bunches and large berries; the black clay, early ripening and great sweetness. A large production of sugar, from which wine acquires its peculiar strength, is found only in dark clay and calcareous soil: the vineyards on the light-coloured Jura lime and white chalk yield a rich gathering, but a much weaker wine. The darker the ground is with humus, the greater is the quantity of sugar in the beet. Manuring with turf mouldering in the air has afforded the richest harvest of sugar-beet; the formation of sugar in beet is almost entirely prevented by ammonia and fresh animal manure.

The process of nutrition through the gradual transformation of the humic particles dissolved in the water, the humic extracts, and humates, may be traced through every step, which is quite impossible according to the carbonic-acid theory.

The leading fact is, that the materials of the sap are imbibed from the soil with the water, but that carbonic acid and carbonate of ammonia are not found in the water, and that these substances are not found in the raw sap. Nothing is more natural than that we must find in the imbibed raw sap those materials which, after the Ingenhousz-Saussure theory, are the chief nutriment of plants. Let them come whence they will, whether from the air or from the ground, they must be present in the raw sap, if they are really the nutritive matter of plants. But since they are not found there at all, they cannot belong to this category. It is, moreover, quite impossible to explain the origin of the matters which really exist in raw sap (as gum, sugar, tartaric acid, gallic acid, malic acid) from carbonic acid and carbonate of ammonia, which, however, must be the case if that theory is true. On the contrary, the origin of all the component parts of the sap from the constituents of the water which we have enumerated, is easily and fully explicable, since the altered constituents of humus really exist in the sap of plants.

The near relation of humous extract to grape-sugar was pointed out by Saussure, though possibly without knowing that this was a constituent of sap, and in ignorance of the presence of dextrine and its relation to humous extract. These relations, in the perplexity of the views which have arisen from the carbonic-acid theory, are never mentioned. Sprengel, who was the first, after Saussure, to examine humus completely and to exhibit its different salts, set out from the notion that humic acid alone, in the form of humate of lime, was the prime nutriment. Liebig contended against this view; and it is easy to prove that neutral humate of lime is not the only or the chief nutriment of plants, since, independently of their difficulty of solution, neutral salts cannot be directly assimilated, as I have proved.

Sprengel, as well as his opponents, had overlooked the importance of humous extract and perhumates. Liebig was exasperated against the notion of the reception of humous extract by plants, since this is brown, while the juice of plants is mostly colourless. It was overlooked, however, that very weak solutions of humous extract, as those in river-water or surface-water, are often quite colourless, though when concentrated by inspissation they become brown. The clearest waters of mountain-streams contain humous extract, since by evaporation they give a dark-brown residuum.

On the other side, Liebig was not aware that the colourless sap of such trees as birch and maple yields a brown humous residuum when evaporated, as I have proved by experiment. The brown tint, therefore, of humous extract is no argument against its imbibition from water.

The humous extract imbibed, together with humic acid and perhumates, forms the foundation for the formation of dextrine and sugar in raw sap, whence the gum is transformed into sugar. The dextrine is therefore, at first, of a humous brown, as also grape-sugar. The formation of all the constituents of sap out of the humous particles dissolved in surface-water and river-water, which may be regarded as belonging to the same category as the bituminous particles in the older alpine formations, and in consequence the process of nutrition, may therefore be regarded as incontestable. The further development of these constituents into vital sap has been followed out by us in our treatise "On the Discovery of the Mode of Nutrition in Plants," through observations on the respiration of plants, according to which the oxygen given out does not arise from the decomposition of carbonic acid, but simply from the decomposition of the hydrated vegetable acids, or the mineral acids containing sulphur and phosphorus. All this was inexplicable according to the earlier notions on the nutritive power of humus, while the facts which have been detailed were unknown. This was the cause of the value ascribed to the carbonic-acid theory, and of the practice of manuring in gardens and in the fields being so perplexed; so that it was a matter of absolute necessity in behalf of agriculture and horticulture to get rid of the errors of this theory; while it is a subject of regret that, in botanical teaching, theories the most contrary to nature and in contradiction to all practical experience, and leading only to botanical perplexity, should be preferred. It was necessary to show previously that it is not the air, but the water alone, which conveys nourishment—that the nutritive matter is dissolved in water, by means of which it preserves its nutritive powers—and how it works.

The observations of the long-sustained vegetation in many succulent plants, as *Sedum*, *Epidendrum*, *Tradescantia*, are very deceptive as regards the carbonic-acid theory and the nourishment of plants from air. Such plants when hanging in the air, while the pots are unwatered, flourish only after having first formed fleshy stems, shoots, leaves, or other organs, and then, like a ger-

* Literally had been converted into Allang-fields, a term explained below.

minating potato, live at the expense of the fleshy organism, which is at length completely exhausted—which frequently happens for many generations, as the older portions die off and the young shoots are developed. This happens especially when the plants are in rich ground up to the time of flowering, when the young shoots, as also the blossoms, live from the nutritive matter laid up in the older stems. These phenomena are easily explicable from the laws of anaphytosis, though not comprehensible from those of metamorphosis. It is never possible to raise a plant from germination into a perfect individual in pure sand, in distilled water, or in pure air, without any nutriment from soil. All attempts, since the days of Bonnet and De Geer, have failed. Plants raised from seeds germinating without soil die off as soon as the nutriment which was laid up in the albumen or cotyledons is exhausted. No one has ever been able to raise plants from germinating seed, irrigated with water containing carbonic acid, or in air charged with carbonic acid: carbonic acid acts as a poison on germinating plants, as it does on animals; and it has been a mere superstition of many savans, causing them to dream of the possibility of such aerial nutriment, while they do not see with open eyes the real course of nutriment, and it can only be a matter of surprise that so many cleave more to the old botanical superstition than to reality.

The knowledge of the fact that so-called pure water—pure spring-water, pump-water, river-water—contains an inexhaustible supply of nutriment—the knowledge that water is the real staple of nourishment to plants, as also of the gradual development of the constituents of raw and elaborated sap from the ingredients in water, is calculated to throw light on many puzzling phenomena in vegetable physiology and culture; and it is to be hoped that it may contribute to the understanding of many circumstances of vegetable nutrition which were formerly explained artificially and unnaturally, from ignorance of circumstances which might have suggested a better explanation. The art of making water nutritious will be the true aim of horticulture and agriculture.

MODERN PLANT NAMING.

A French botanical author ridicules, in a vein of irony which will scarcely survive a free translation, the frivolous distinctions upon which genera and species of plants are often established, and the slender claims to discovery which led to personal names being assigned to, or assumed by, the minute philosophers who make such distinctions:—"I have not ended (he says) the enumeration of the pleasures of the plant-gatherer; there is still another source of satisfaction, the liveliest of all perhaps—it is that which he finds in the indulgence of his vanity. It will be readily understood that I speak here only of a certain class of collectors, and not of earnest scientific botanists. He of whom I wish to speak is proud to be the sole possessor of a species—proud to be the only man who has gathered it—unspeakably proud to be alone in the knowledge of its habitat. What would he not give to be the discoverer of a new species—still more, to found a new genus, and distinguish it by his own name! The ambitious thought fills and fires him with a charming enthusiasm which takes the very sleep from him, and often prompts him to rise before the sun, and go forth hopefully upon the theatre of his explorations. There are certain rare plants the characters of which are imperfectly known, because the authors who have described them have been able to examine them only in the dry state. Who knows but they may have confounded them with allied species, or even united two distinct genera in one? Our herborizer searches after such plants with a curious interest: the most insignificant details of their structure become to him the objects of a minute analysis. If he meet with the slightest exceptional character, or even with a simple variation in size or colour, the difference acquires exaggerated proportions in his eyes. He readily persuades himself that he has made the discovery of a new type, and he knows no rest until his name—he it French or Teutonic, ending in *our*, or in *ard*, or in *ier*, or in *ach*, or in *mann*, or in *berg*, or in *ski*, or in *dorf*—can be lengthened by the Latin termination *ii*, and made to constitute a generic name. I figure to myself one of these ecstatic monomaniacs falling upon a rare species, which he has long been in quest of, and I think I hear his exulting soliloquy:—

'O happy day! O most auspicious hour!
And happiest botanist in Flora's bower!
To whom alone a species stands revealed,
Long sought in vain o'er many a weary field,
And here at last it bursts upon my sight,
And here at last I welcome with delight,
Which future memories shall oft revive,
A plant Linnaeus never saw alive.
Caducous petals! fleeting anthers, too!
Ye could not, though ye would, elude my view:
Your organs marvellous, which now I see,
Shall never more be mysteries to me.
Pistil! I hail thee with fond admiration!
Stamens! receive my loving salutation!
But what see I there?
An articulate hair
At each nectary's basis, I vow and declare!
Linnaeus's description fails
In one of the essential details.
That jointed hair, now first disclosed to view,
Behold! to science adds a species new,
And henceforth it shall flourish in the books
Under my name—the immortal name of Snooks!
And, consecrated there, as ages fly on,
Shall o'er the world be known as Snooks's Dandy—lion!"

Correspondence.

INFLORESCENCE OF *BOHMERIA ARGENTEA*.—Could you kindly give me some information respecting the enclosed specimen? I have shown it to several gardeners and nurserymen, and they all say they never saw anything like it, and don't know what it is. It was supposed by one to be a malformation of the leaf at first, but I don't think it is that. The plant from which it is taken (*Bohmeria argentea*) is between three and four feet high; it has been pinched all the winter in a smallish pot, and sometimes has been very dry. Directly after Christmas it began to throw out these things from the base of the leaf, one about half-way up, and two more near the top; it is throwing out another now at the top. My own opinion is that they are similar to the catkins of the hazel—in fact, the male blossom. The reason it was punished so is this—it was to be thrown away through being too tall for the place, but when I found it throwing out those curiosities, I kept it on to see what they would come to? Would it do any good cut down? PERPLEXED ONE.

[The specimen sent is a tuft of long thread-like stems, of a brown colour, to which are attached a few scattered brown scales. In the letter in which the specimen was enclosed is a little heap of brown dust. *Bohmeria* belongs to

the natural order *Urticaceae*, and produces its minute flowers, which have four angles on thread-like racemes, of which the specimen sent is an example. In passing through the post the flowers have been reduced to dust, and the stems alone remain intact. One of the stems measures 30 inches in length. It is a rare occurrence for this plant to flower, and in the present instance is no doubt due to the starving process to which it has been subjected. If any yet remain intact on the plant, a good lens will reveal their character. The flowers resemble in some degree four arms proceeding from a central axis. These arms are the calyx. Beyond them project four oval bodies; these are the stamens. The central axis is the pistil. The fruit is a star-like body, and consists of a number of nearly globular nuts, each furnished with a horn-like process.]

Replies to Queries.

Greenhouse Vermin.—W. B., Gresham Street.—From the few particulars you give of your plants, we conclude that they neither want smoke nor pastils, nor any other medicament. But they want more air and more water; they are too hot, too close; they are in an insect-breeding atmosphere, not a plant-growing atmosphere. It must be so if azaleas and camellias are smothered with fly immediately after the employment of tobacco, Keating's Powder, and other remedies. Turn the plants out in a shady spot, and syringe them over head every morning, and the vermin will soon disappear.

Geraniums Diseased.—W. S.—The plants that are affected like the sample sent have for months past been in a bad state at the roots. Probably the drainage has been choked by worms, and during the miserable weather of February, March, and April they were becoming more and more soddened and sour. Shake them out, prune back the roots a little, and repot them, using an extra bed of crocks and an extra quantity of sand, and put them on a hot sunny shelf, where they will no doubt recover in a few weeks.

Heating a Small Plant House.—J. T.—A stove burning coke or coal in a very small greenhouse will be likely to destroy all your plants, or at least spoil the best of them. We know of nothing so good as Hays's Constant Stove, both because of its efficiency and harmlessness and the comparative cheapness of the fuel used. Owners of small plant houses intending to use such a stove next winter should obtain both a stove and a store of fuel now, or at all events before autumn. Last winter the demand for stoves and fuel exceeded the means of supply, and many persons lost their plants because they could not obtain either. A still cheaper contrivance is the upright cylinder stoves made by Swan Nash, of Newgate Street, London, and called "Joyce's Patent." In this common charcoal can be burned, and that we suppose can be obtained in any part of the country.

Hardy Plants in the Parterre.—S. W. B.—There is no difficulty at all, except in your own imagination. You want a piece of open ground, rather sandy if possible, and this should be your nursery. On this ground plant out the various subjects, whether raised from seeds or cuttings, clear the beds of the geraniums, verbenas, &c., as soon as they begin to decline in autumn, say early in October, and then transfer, by simple transplanting, the herbaceous plants from the nursery piece to the parterre, and so arrange them that their colours in spring will make a tasteful display. When they have done blooming, say in the middle of May, take them up and plant them again in the reserve ground, and so on from year to year, taking care occasionally to get up fresh stocks from seeds and cuttings, that the old plants may be destroyed. As for subjects, the best are to be found in such genera as Iberis, Arabis, Alyssum, Cheiranthus, Saponaria, Phlox (alpinus section), Myosotis, and Primula.

Perishing Spruces.—C. W. C.—The description given of the spruces, which are getting leaner every year and losing their leaders, pretty well convinces us that when they were planted the ground contained many dead roots of former trees, and that these dead roots have given rise to a growth of mycelium of fungi. When this takes place trees are sure to die. We could point to many great places where the handsomest specimen coniferous trees are doomed, and have already the seeds of speedy decay in them, derived from roots of former plantations. There is no cure for it at all. The preventive is a thorough cleansing of the ground before planting. Wherever white silky fibres are seen running amongst dead wood the most potent of tree-killers is revealed.

CATALOGUES.

JAMES CARTER AND CO., 237, HIGH HOLBORN. *Vade Mecum, Part III. List of Stove, Greenhouse, and Bedding Plants for 1867*.—A huge book, crammed full of interesting papers on sub-tropical plants, foliage hedges, and bedding effects. It is truly a "Vade mecum," and well worth the shilling at which it is offered to a discerning public.

WILLIAM BULL, KING'S ROAD, CHELSEA. *List of New and Beautiful Plants for 1867*.—A valuable list, for the novelties announced are in many cases plants that have been much exhibited, and have thoroughly established their character. We see announced a whole batch of double-flowering Zonale Pelargoniums, two new Continental Roses, viz., *Comtesse de Jancourt* and *Madame Martin de Besse*. Cultivators and collectors of choice subjects should at once obtain this list.

CHARLES TURNER, SLOUGH. *General Spring Catalogue, 1867*.—The usual substantial list of Auriculas, Carnations, Picotees, Azaleas, Dahlias, Pelargoniums, &c., &c. The Slough collection is the richest in England in florists' flowers.

F. G. HENDERSON AND SON, ST. JOHN'S WOOD, LONDON, N.W. *Catalogue of Stove, Greenhouse, and Bedding Plants*.—Amongst the special announcements occur *Blandfordia Cunninghamii*, one of the grandest greenhouse plants known, and which is likely to add much to the beauty of the flower-garden in summer. There are batches of new Pelargoniums, Verbenas, &c., &c., with many of which our readers are already more or less acquainted. The catalogue is indispensable to connoisseurs in Tricolor Geraniums.

CHARLES GUY, MONKTON NURSERY, RYDE. *Spring Catalogue, 1867*.—Contains everything in demand at the present time for greenhouse and garden, and the lists show that Mr. Guy keeps pace with the times in placing the best subjects before his customers, and weeding out to make room for them such as they have superseded.

T. SAMPSON, YEovil, SOMERSET. *Catalogue of Bedding Plants, Roses, Conifers, &c.*—This is of more than average merit, many of the subjects being carefully classified according to their styles and colours. The arrangement of the geraniums is particularly good.

The Gardener's Magazine.

SATURDAY, MAY 25, 1867.

GRAB-ALL IS THE NAME OF A SECT. It consists of exhibitors who practise clutching, and are not particular about ways and means. A high-priest of this sect is one who can scarcely grow a plant fit to be seen on an exhibition table, but is good for gin-and-water and the sweepings of the van-yard. On the day of the show he hovers about. He enters as an exhibitor, and by this means is enabled to read over the several competitions as the plants are being staged. If he observes a deficiency somewhere, he generously proceeds to amend it, for his own good solely. He goes about, he smiles, coaxes, and perhaps swears (jocosely) a little; and the gross result of the gross proceeding is that he manages to borrow odd plants, and makes up a few exhibitions in his own name, and pockets a few prizes. Grab-All is his doctrine, and his heaven is Swag. Our readers must pardon the low language we use, for this is a low subject. But our object is not a low one, for we desire to see exhibitions purged entirely of the Grab-All class. The question is how to do it. Probably one step towards the consummation so devoutly to be wished would be for managers of exhibitions to leave off winking. They wink at the black marauders, knowing well of their movements; and the motive for winking is to have the tent as well filled as possible, and if half a dozen good groups are made up in this way the manager's conscience is satisfied—he has tolerated evil that good might come. But it is not good, after all; it is an evil that strikes at the very root of success in exhibitions. High-minded men who are beaten by such tricks are filled with loathing, and they give up exhibiting because of the superfluity of trickery that is practised. To the uninitiated it may appear strange that such things should occur; but given a capacity for lying, and the thing is easy enough. An exhibitor must make his entries prior to a certain date, and give a guarantee that the plants to be shown have been in his possession a certain length of time. This is easy enough for a man who does not possess a plant of any kind, and who perhaps could not produce one fit for exhibition in any length of time. A man without honour thinks nothing of a declaration, even if there be not a particle of truth in it. Genuine exhibitors, who really grow plants for exhibition, usually take with them a few more than they intend to put up, and the priests of the Grab-All sect go about begging the use of these surplus specimens, and by hook and by crook make a respectable appearance at last, pocketing prize-money dishonestly won, and rewarding their benefactors in liquor. It is no fiction; it is a dreadfully commonplace fact, and is so well known and understood that exhibitors will feel the force of these remarks, whether they approve of them or not, and their disapprobation will not trouble us.

There has been much discussion about the prospects of exhibitions, and how exhibitions may be improved. Now, we say it advisedly, the first step towards the improvement of exhibitions should be the establishment of an inviolate system of honest showing. Every man who objects to have his pocket picked or his name defamed should put himself in an attitude of antagonism to systematic borrowing for impromptu competitions. A man who can grow plants should be hatefully jealous of one who cannot grow them, when grower and non-grower are to be placed on equal terms before the judges. Honest men should stay their hands, and keep their generosity for better objects. When the borrower makes his customary appeal, he should be refused; for it is quite certain that, apart from the low motive by which he is actuated, he is otherwise worthless. He will be found ready to lick the feet of any man who has a little money, or who can do him a good turn. He will be found to be as full of treachery as he is of deceit—a humbug on a committee, a blackguard in a social gathering, a hypocrite at a public meeting, and a liar at any time. Why do not respectable men, who would never put their hands to a dishonest deed, put an end to this miserable business, and shut up the Grab-Alls for ever? They can do it; they lack only moral courage, and an appreciation of the fact that good-nature is pernicious when it promotes evil ways.

Mr. D. T. Fish has made a proposal which, if it meets with a favourable reception, will do something towards the moral purification of the exhibition tent. He proposes to give cups instead of money, and there are some spirited men who would prefer cups or

No. 108, NEW SERIES.—VOL. X:

any valuable article worth keeping to money of any amount. Still there are, on the other hand, worthy men—men whom it is a pleasure to meet and an honour to know—who despise “gcwgaws,” and prefer money, for the very good reason that they can put it to a better use than cups or medals, or any other elegancies. Nevertheless, the cup-system is worth a fair trial, and a system of medals is worth trying; but the society attempting either must have high prestige, and be everywhere known, or the honorary awards will be of no value. We shall never quite do away with money prizes; they add to the income of the professional cultivator, and have actually helped in no small degree to set up in business some of our best nurserymen. Nevertheless, when amateurs exhibit in their own name, as is frequently the case where florists' flowers are encouraged, money prizes are no attraction, a bit of ornamental gold or silver would be much preferred; indeed, we believe money to be objectionable, and when naught else is to be got we know that many gentlemen who would exhibit in their own names keep away; they could not touch the money, yet would gladly take some memento of having exhibited and made a good position. The gardeners always look for money, and we cannot blame them, for they do not earn over much in the shape of wages, and exhibitions afford them the means of improving their social position and putting something aside for a rainy day. The system of the Royal Botanic Society is admirable in this respect. All the prizes are nominally in medals, but winners can take the value of the medals in money if they prefer it, and for the most part they do prefer it, and there can be no complaint made either way. Every thriving society should do the same, especially in the country; for there are always exhibitors to be found who would prefer a medal for the simple reason that they covet honour and are not in need of cash. Small societies can scarcely attempt this, because the cost of getting up medals is considerable in the first instance. But even the smallest could act upon the medal principle, and offer elegant objects in certain classes instead of money, and they would gain the esteem of many who now hold aloof from them by the proceeding. We frequently observe that prizes of 5s., 10s., 15s., or even of the enormous sum of 20s. are offered to ladies (!) for dinner-table decorations, bouquets, window plants, and other cognate subjects. We cannot but think the ladies would prefer an offer of elegant books, or silver teapots, or trinkets, in fact, of anything acceptable except money.

But coming back to the Grab-Alls, we must beg to be allowed to characterize them as the Bohemians of the exhibition tent; a race to be put down or cut up, to be snubbed by managers, disqualified by judges, shunned or tormented by honest exhibitors. Like vermin, there is no infallible specific for their extinction, but they may be kept in check by the determination of men who really can grow plants to give the quietus to those who cannot. Let this be done; let there be an exhibition of public spirit as well as of plants and flowers by horticulturists this season, and we may see the beginning of the end of a nuisance. The Grab-Alls have already made exhibitions to be mere shops and gambling booths in many instances; surely we do not need to go any further downward; the case is quite bad enough to need mending, and those who love plant-growing apart altogether from what they gain by it, and who would scorn to profit by falsehood and trickery, are the men to purge the tent of its corruptions. We leave the case to men who are worthy of respect, begging them to call to mind what they used to write in their copy-books, and which is taken from the best of all books—“Evil communications corrupt good manners.”

THE DECLINE OF FLORICULTURE is the subject of occasional despondent utterances of a class who appear to consider it the highest attainment of patriotism and virtue to utter lugubrious bewailings on this subject. Having delivered themselves of some stale regrets, and flattered themselves that they have made a display of the sublimity of grief in the presence of wondering novices, they go to sleep and slowly gather strength to repeat the same vain regrets, and play the same farce of pretending to mourn over the departed glories of the exhibitions that were wont to be constituted entirely of genuine florists' flowers. We can call to mind a few public writers who for twenty years past have indulged in this nonsense, and we could point to a few of their lachrymose successors who, like undertaker's men or hysterical women, appear to have tears always at command, and who do little else than feign to weep

at every opportunity offered them to bewail the decline of floriculture. We have not seen these ministers of woe busy in attempting to discover the causes of the alleged decline; they could always bellow to Jupiter, but they could not put their shoulders to the wheel. With the permission of all whom it may concern, we will point to one of the causes of the decline of floriculture. The one cause to which we now direct attention is the practice with the florists of hiding their light under a bushel. They labour the whole year round to produce a show; the show takes place at last; but having failed to inform the world thereof, they have it all to themselves, and it is so dull, so wearisome, so absurd to make an exhibition and have no company, that a few of the active spirits drop out of the ranks every year, and as the general public know nothing about the movement, there are no recruits to keep up the force. It is quite a common occurrence for notices of shows to come into our hands a few hours before the time fixed for their opening, and quite a common thing for reporting of such affairs to be left unattempted because of previous engagements, and the impossibility of employing balloons and express trains on this sort of business. We could point direct to several societies that are perishing solely through the habitual negligence of secretaries in sending out notices of meetings; the notices are sent at the last moment; very few respond to them; and the absurd verdict is pronounced that "men who ought," &c., &c., care nothing at all about the movement, though the "men who ought" have been booked long before for other business on these occasions. It will be remembered that not long since we called attention to the snug manner in which the committee of the "National Auricula Society" reserved the announcement of their exhibition for an obscure monthly work that never had a position, and that perished very soon after that announcement was made. They had resolved to light a candle—true, it was but a dip—and proceeded slyly to hide it under a bushel; first, that nobody might see it, and secondly that they might have reason to complain bitterly that its beauty was not praised. National societies should have national aims, be animated by a broad and generous spirit, should not become the shibboleths of small cliques and parties, should know of no interest but the interest of the cause, whatever it be, to which the term "national" is applied, and should labour much more for the good of the nation than for the gratification or profit of their promoters and officers. When we find floral societies acting in a generous and impartial manner, we always take care to give publicity to the fact; but we dare not name all the instances of jobbery and cliquism that come under our notice, and can only deal with the case generally, and leave it to others to make the application.

But in many societies that are conducted in the most upright manner, and where there are no interests to secure, the practice of putting the light under a bushel is so steadily persevered in that it is evident the light must soon go out, and the dark empty bushel will remain as a token that the life was wasted, and opportunities were thrown away. We have just been compelled to witness an example of a movement in process of decline through this very cause. The Amateur Tulip Society, meeting annually at the Greyhound, Dulwich, must shortly cease to be unless reformed. In every respect except one it is admirably conducted. The members are men of the highest private worth, who cultivate and exhibit out of pure love for the flower. They have no secondary ends to gain, but so long as they hold a public exhibition, they must bear the public responsibility of praise or blame, according to the prudence or otherwise of their endeavours. In years gone by a trip to the Greyhound to see the tulips was one of the pleasantest pastimes for London florists in the month of May. Since that time the railway has diverted attention from the romantic village and the very respectable Greyhound. More than this, it has diverted coaches and omnibuses, and to reach the Greyhound, except for such as live next door to it, is pretty well a day's work. Good society, good flowers, good house, good landlord, nice dinner, lovely spot,—what a feast! and in the midst of the feast a skeleton. Our report says, in respect of the attendance of the public at the exhibition on Monday last, that one lady entered the room after the flowers had been removed. Was that the only visitor? So we infer, and are in no way surprised at it. To get up a show needs a knowledge of floriculture; to make it a success requires some knowledge of public business, and, at all events, some earnest endeavour to ensure publicity.

AMATEUR TULIP SOCIETY.

The exhibition by this society took place as usual at the Greyhound, Dulwich, on Monday last. Considering the season, and the few encouragements such flowers as the tulip meet with in these days of sensational gardening and bedding to excess, there was an admirable display. In the section for COUNTRY GROWERS, the 1st prize was awarded to Mr. N. Norman for *Rosa*, *Cerise Primo*, *Anastasia*, *Triomphe Royale*; *Byblomens*, *Salvator Rosa*, Mrs. Pickercoll, Mrs. Norman; *Bizarres*, William King, Sunbeam, Mrs. Ingleton. 2nd, Mr. J. Brown, with *Ro.*, *Heroine*, *Rose Celestial*, *Anastasia*; *Byb.*, *Violette Aimable*, Walker's Duchess of Sutherland, Princess Royal; *Biz.*, Caliph, Sir Joseph Paxton, Ulysses. Equal 3rd,

Mr. Mercer and Mr. Phillips. In the section for TOWN GROWERS, 1st, C. Williams, Esq., of Harsey, with *Ro.*, *Triomphe Royale*, *Seedling*, *Cerise Blanche*; *Byb.*, Walker's Duchess of Sutherland, Lady Denman, General Bournanville; *Biz.*, Everard, Delaforce's King, Mr. F. Perkins. 2nd, B. Williams, Esq., of Stamford Hill, with *Ro.*, *Aglaia*, Groom's Duchess of Sutherland, *Claudiana*; *Byb.*, General Barnevelde, Walker's Duchess of Sutherland, Siam; *Biz.*, Truth, Dr. Horner, Mr. F. Perkins; 3rd, Mr. Reeves; 4th, Mr. D. Aust. There were a few spare flowers shown, amongst them were some of very high merit, particularly Elizabeth Norman, General Barnevelde, and Sarah Headly. There were only some ten or twelve exhibitors in all, and no company. We beg pardon, we saw one lady enter the exhibition room after the flowers had been removed. The evidences of dullness and decline were somewhat relieved by the high quality of the flowers shown, and the unexceptionable good character of the winning stands; but still more perhaps by the fact that we saw the same names that we have seen again and again for years past, and in much the same positions as on previous occasions. We see in this an agreeable exemplification of the force of habit and the value of persistency and perseverance. Tulips have had a trying time this year, and it is creditable to this old established society to be able to make a show at all.

SOUTH HACKNEY AND HOMERTON TULIP SOCIETY.

The exhibition of this society took place as usual at the Lamb and Flag Tavern, Homerton. It was a good show, and comprised collections of twelve only throughout. 1st, Mr. Summers with *Terriff* (?), *Isabella*, *Cerise Royale*, *Aglaia*, *Leonidas*, *Joseph Hume*, *Barnevelde*, *Lady Jane Grey*, *Thomas Williams*, *Caliph*, *General Gough* (fine), *Heroine*. 2nd, Mr. Gaunt with *Albion*, *Triomphe Royale*, *Queen of Beauties*, *Rose Aglaia* (fine), *Plantagenet*, *Trebizond*, *Grotius*, *Mahomet*, *Father Gavazzi*, *Emperor of Austria*, *Mountain Sylph*, *Princess Royal*. 3rd, Mr. Bishop with *Mountain Sylph*, *Glory Alborum*, *Marshal Sout*, *General Barnevelde*, *Polyphemus*, *Livin's Charles Dickens*, *Terriff* (?), *Triomphe Royale*, *General Gough*, *Plantagenet*, *Platoff*, *Miss Catherine*. 4th, Mr. Disley with *Julien*, *Belleforme*, *Juliet*, *Charles Jeffries*, *Abd el Kader*, *Commissioner*, *Ponceau de Blanc*, *Trebizond*, *Mahomet*, *General Gough*, and *Father Gavazzi*. 5th, Mr. Stimson with *Star of Venice*, *Anastasia*, *Maid of Orleans*, *General Gough*, *Costum* (?), *Rose Emily*, *Triomphe Royale*, *Joseph Hume*, *King John*, *Polyphemus*, *Mason's Matilda*, and *Revenge*. 6th, Mr. Stillwell with *Polyphemus*, *Rose Aglaia*, *Grotius*, *Vicar of Radford*, *General Gough*, *Catalina*, *Franklin's Harriett*, *Eldorado*, *Lord Byron*, *Charles Jeffries*, *Heroine*, *Violet*. 7th, Mr. Tilber with *Sphinx*, *General Gough*, *Lallah Rookh*, *Rose Aglaia*, *Charles Jeffries*, *Empress Eugénie*, *Disley's King*, *Triomphe Royale*, *Don Capett* (?), *Ophir*, *Goldham's Maria*, and another. 8th, Mr. Bratt with *Optima*, *Rubens*, *Ponceau de Blanc*, *Rose Aglaia*, *Costum* (?), *Harriett*, *Bacchus*, *Rose unknown*, *Charles Jeffries*, *Emperor of Austria*, *Wade's King*, *Magnificent*. 9th, Mr. Addicot with *Catafalque*, *Ponceau Rose*, *Sir Sidney Smith*, *Ponceau Sanspareil*, *Emperor of Russia*, *Orion*, *La Reine*, *Surpass Catafalque*, *Camuse de Craix*, *Charbonnier Noir*, *Leomedam* (?), and another. In addition to the foregoing, Mr. Disley put up twelve nice flowers, including two unnamed seedlings, not for competition. The ten named varieties were *Lord Denman*, *Triomphe Royale*, *Disley's Exile*, *Father Gavazzi*, *Disley's Camlypus* (?), *Vicar of Radford*, *Mrs. Ashton*, *Mrs. Disley*, *Eldorado*, and *Towley's Queen*. The reporter took in every case the names appended, but a few of them appear to be apocryphal; to these, in correcting the lists, we have appended notes of interogation.

PARIS UNIVERSAL EXHIBITION, 1867.

(From our own Correspondent.)

No. II.

Your contemporaries have had so much to say about the Exhibition, that I am afraid you will think I have been consigned to the Morgue, or have built a nest in a tree in the Champs Elysées, and gone to sleep in it. Well, the reason of my long silence can be explained in a word. I have seen very little worth reporting on, and I was instructed by you not to report for the sake of filling columns, but solely for the purpose of conveying useful information. Well, things are looking up in our department. We have had an outburst of intensely hot weather, followed by weather intensely cold. Paris has been an oven and a refrigerator, and horticultural matters, you may be sure, have been greatly influenced by the extraordinary weather. And talking of the weather reminds me that the other day I was discussing with M. Chauviere about it, and he explained to me that the cold was the consequence of the heat, just as extreme prostration must be the consequence of a season of unwonted activity. He says the extravagant heat resulted from a blast of hot wind that came direct from the tropics, and the blast of cold was simply the "return current" direct from the north pole. I can understand that if a breeze goes up one way it must come down another. Of course, it is a very great comfort to have these learned explanations, though they do not exactly cure one of the catarrh caught through untimely reduction of one's clothing, or restore to life tender plants that were put out in the belief that summer had set in *en permanence*.

English gardeners will, I think, be generally pleased with the sample of English style displayed in the "Paro," though they may find therein a few things to laugh at. This part of the park is now being dressed up for summer, and will, I am quite satisfied, prove a success; and it will probably furnish to my unhappy country, which I hear is being ruined by the Compound Householder, some new ideas in out-door embellishments. In the Champ de Mars there is now a nice sheet of grass-turf as could be desired, raised, I am told, from seed supplied by Messrs. James Carter and Co., of High Holborn. Now, I must tell you that the grass used in Paris for such purposes is invariably the true Italian rye-grass, which endures the heat better than any other kind, quickly makes a close sward, and keeps growing and growing till very late in the season. All kinds of fine lawn mixtures have been tried and failed, but the rye-grass never fails, and may be sown at almost any season, though of course the best season is early in the spring, when vegetation of every kind is waking up. The plant houses here are richly furnished, and on every hand surprises occur in the shape of fine groups of plants, fine specimens, and bits of curious colouring. The sub-tropical movement is to be vindicated here and everywhere, and more especially in the inner garden, which, though not yet planted, has been described most elaborately in the English newspapers. Within a few days of this, however, wonders will be done, and the last stroke will be as if a curtain had been withdrawn from a work of art that has been in pro-

gress for years, and is at last wrought up to a condition of unsurpassable splendour. If the park and central garden are not wonderful places in respect of richness of display, and perfection of taste in grouping and contrasting, very early in the month of June, I shall never again believe in good intentions.

To report the exhibitions that have been held already would be absurd. You would have to print an extra sheet weekly, and charge a shilling for it; for very few, even amongst the most enthusiastic English horticulturists, would care to see more than one such report. But let me speak of some things that are really interesting, and remembrances of which will be lasting and pleasant.

The collection of coniferous trees in the garden in the south-eastern part of the Champ de Mars is the best exhibition collection ever seen. The first prize for the best miscellaneous collection was awarded to M. Desoigne, of Bougival, for a group comprising 350 plants. Messrs. James Veitch and Sons took the first prize for new kinds and the best 50 species; and M. Seneclausse took first place for trees used in the arts. Amongst the kinds especially noticeable in these groups, I must name *Larix Kempferi*, a beautiful specimen 10 feet high, and which perfectly justified the complaint made in the GARDENER'S MAGAZINE against M. A. Verschaffelt's picture; the tree is, in fact, far more beautiful than any picture has hitherto represented it. In Messrs. Veitch's group I noted *Retinospora plumosa* as one of the most elegant of the smaller kinds of conifera hitherto introduced to Europe. The habit is light and graceful, the branches and branchlets all showing distinctly, like sprays of lycopodium; the colour being a fine glaucous hue, almost metallic. From the same exhibitors came the pretty *Retinospora filifera*, which grows in a pyramidal outline, and produces numerous drooping shoots, which become crested at the tips; the colour is brilliantly glaucous. *Thuja dolabrata*, with all the new growth showing a brilliant golden hue, is equal in splendour of form and colour to the most superb fine-foliage plant ever staged in an exhibition. I was rather surprised to see that the premier place in the whole collection was assigned to *Thuja gigantea*, which undoubtedly is a glorious tree, and the specimen shown could perhaps not be equalled anywhere in Europe; but there was a *Wellingtonia gigantea* of faultless proportions, and an *Abies Khotrow*, that might have been likened to a mountain made of bright green ostrich feathers, and a *Cedrus deodara*, with new and old growth mixed together in such a charming manner that was as good an emblem of day and night, and even of life and death, as the wreath of poplar leaves that Hercules bound round his brow when he went down to hell (in Greek fable), and got the outsides of the leaves darkened in colour, as we now see them on the tree, while the undersides remain white. Let me not forget *Retinospora ericoides*, which is so well adapted for introduction to the parterre, to break up the formality of the colouring; and *Retinospora obtusa*, *R. pisifera*, and *R. leptophylla*, as also worthy of the attention of your readers who love beautiful trees. The collections of Yews are very interesting, and full of suggestions for variations in out-door display, their solemn outlines and colours being in many cases calculated to enhance very much the brightness of green grass and the glow of beds of flowers. Touching other garden conifers, I have been deeply impressed with the beauty of *Cupressus macrocarpa*, which is undoubtedly the same as *C. Lambertiana*, let the makers of varieties and dividers of species say what they please. I have always cherished the notion that *C. Lawsoniana* was the best tree of this genus, but now I incline to the opinion that *C. macrocarpa* should have the first place; it is so neat in growth, so vigorous and accommodating (you remember there are good examples of it in the Royal Horticultural Society's Garden at Kensington), and so peculiarly fresh and distinct in colour. But let me not by implication lessen the esteem in which *C. Lawsoniana* is held; its beauty is of another kind—it is dark, massive, majestic, and has its place in the list of indispensables.

I have spent a good deal of time in admiring the specimens of trained fruit-trees, of which there are many. But I must confess that amongst these trees there are examples of extravagance as well as of utility; many of the cultivators have evidently just made up their minds to show what they could do, to illustrate possibilities in fact. Take a nicely-shaped juvenile pear or plum, and bend all its branches back, so that they can be tied to their parent stem; now graft the points of those branches to the stem, and what a queer thing you have produced, and how utterly useless! Now take another tree, and train the outside parts of the main branches round and round on an imaginary wheel placed at the circumference of the tree, and graft them together, so that the tree forms a hoop of its own, within which all its leaves and fruit are enclosed—very curious, very clever, but, like an elephant I saw in London just before I left, and which blows a farthing trumpet, and tosses a penny like an experienced street-gambler, of no earthly use, and really indicating that the producer thereof loved to waste his precious time. But never mind, there are two trained peach-trees on a white wall that I particularly wish English gardeners who are coming here to enter in their note-books at once as things they must see. I shall not attempt to describe them, save to say that they are covered all over with varieties; they are multiple trees with a vengeance, and their training and condition are extraordinary. As they happen to be in the immediate neighbourhood of M. Rousseau's plantation of oaks, or rather I should say his truffle nursery, two birds may be killed with one stone. Touching this truffle business, we are no nearer than ever in respect of the rapid production of truffles, which some enthusiasts believe to be possible; but we may be said to have had a trifling contribution to their history from M. Rousseau. It is this: truffles grow plentifully in some plantations of oaks, where the soil is loamy or chalky. So it is inferred that by planting oaks on such soils, and in a southern exposure, truffles may be produced *ad lib.* Well; M. Rousseau speculated in truffle growing; he planted oaks, waited seven years, and then obtained a crop at the rate of 50 lbs. per acre. So he comes here, makes a plantation of oaks, and sticks in the centre of them a case filled with truffles, and visitors admire or despise the whole affair as they please. I do the last-named shabby thing, but possibly my judgment may be warped by the fact that I detest truffles, and have the courage to confess it. And talking of truffles reminds me that in group V., in the French department, the Administration des Forêts exhibit along with forest timber some interesting examples of wild fungi, truffles of course amongst the rest. But, strange to say, there are few collections of fungi of any kind in the whole of the exhibition. I noted in the Spanish department, in group V., the other day, many examples of mushrooms, that I shall pay attention to some wet day; but I want to see samples or models of the species of fungi that we consider poisonous, but which the French, Italians, and Spaniards, but the Italians especially, cook with elaborate

care, and eat (it is said) with indescribable relish. I can find them, I know, in Dr. Badham's hook, and in Berkeley's "Elements of Fungology," and elsewhere *in print*; but that is not enough, I want to see the things themselves, even if dried, or coloured models of them, for I am certain that we might eat more of these things than we have the courage to do at present. In the Italian department of this group there are numerous exhibits of mushrooms and truffles, but none of the questionable fungi, that are said to beat oyster patties, cream-cheese, and custard. That vile delusion *gigantio asparagus* has been shown in plenty. Why do they not disqualify every particle of such trash and imprison the exhibitors? Gigantic! why I saw some that measured five inches round the stem, and it was just fit to lay on the top of a heap of burning weeds to increase the total bulk of the ashes, which are at least useful to scatter over seed-beds. I declare that this asparagus was fit for no other purpose, and I am surprised that there should still be found either Frenchmen or Englishmen capable of such folly as to waste money, time, and land in producing it. I had a few days ago, when dining with M. Barillet, some small purple asparagus, as thick, say, as my thumb, which is not a monster, and every particle was eatable and most delicious; this I was told had been grown in the simplest possible manner, with very moderate allowances of manure, without salt, and in beds of the same level as the rest of the ground. It is cut so as to leave a small stump visible in the ground, and thus many latent buds are spared.

I have been much charmed with the collection of cactuses from various exhibitors. These plants are now everywhere much neglected, and it is really wonderful that so many beautiful examples should have been brought together. Mr. Pfersdorf, of Kentish Town, makes a great figure, but he has plenty of competitors. Apart from the intrinsic beauty of many of the plants, and the great interest that attaches to the collection as a whole, the most amusing part of it is to be found in the extravagancies of the grafting. There are great round-headed spiky masses grafted on slender stick-like forms, a huge head upon three or four thin legs; others imitate the cromlech—there is a great flat growth supported by two upright slabs; some of the Epiphyllums grafted on clear stems are superb in form and elegance, though as curious, too, as most others. Just now I am enjoying the silken gold-coloured flowers of a plant of *Echinocactus concinnus*, the rosy flowers of *E. Anconianus*, the red and pink flowers of *Mammillaria conica*, *depressa*, *echinaria*, *speciosa*, and *pusilla*, all entered in English books as stove plants, but no more needing the stove than a houseleek does; at all events, a greenhouse is enough for them in respect of heat. In the course of making up my notes for permanent use I shall, I hope, be enabled to make a good selection of succulents adapted for private cultivators, for here are opportunities for so doing that are not to be made light of. But, as to that, one might spend weeks in making lists of good things. *Au revoir*. I shall at once devote a few hours to such work.

Garden tools, implements, and ornaments, and agricultural machinery and implements, are shown in abundance, yet I miss many of the notable things that we have got used to at the Agricultural Hall, London, and at Bingley Hall, Birmingham, and at the annual meetings of the Royal Agricultural Society. M. Barriere has taken great pains to prove to me that our machines are not, generally speaking, adapted for French soil. Most of the lands are small, and small properties are prohibitory of steam-ploughs. Then in gardens the grass is thin and wiry; there is not a thick sward, such as we have (that is to say, such as you have, for I ought to speak as a Frenchman now), and there is literally nothing for a mowing-machine to cut. To work a mowing-machine to advantage you want a resisting mass of herbage; if it yields to the edge of the cutter, it is not cut, but passed over. Now, in France the lawn-mower simply lays the grass down, it does not cut it; hence the scythe is the favourite instrument for mowing. As for garden tools, there are many admirable things that would be useful to English gardeners; and I could heartily wish that a selection were made from the best things to be seen here, and transferred to some place in London to remain *en permanence*. This is just such a task as the Royal Horticultural Society might charge itself with, and, indeed, I think the Society might very well make a purchase of such things here as the foundation of a horticultural museum. This would remove the affair out of the region of "shop"; for when manufacturers exhibit on their own account, we are not sure to see all the best things, but we are sure to find it begin and end in "shop." You will be glad to hear that Mr. Wells has brought his "portable ground vineries" here, and has them embellished with artificial grapes. If he does not sell many to Frenchmen, he will, I daresay, to the Yankees and the Danes, Dutchmen and Germans, with whom, and especially the first, Paris is now well peopled.

MANCHESTER NATIONAL EXHIBITION.

One evening last week I took one of my occasional walks through the Manchester Botanical Gardens, and was particularly struck with the extensive preparations that are being made for holding the great national flower show in the month of June next. It occurred to me that a brief account of the arrangements that have been made, and are now being carried out for the occasion, would be interesting to your numerous readers who reside in other parts of the country. It is, I suppose, generally known that there is in the garden a large glass building called the Exhibition House. This structure is 200 feet in length, and 60 feet in width, and in this all the ordinary flower shows are held. All along one side of this structure, and connected therewith, there will be erected a large tent of the same dimensions as the house, and the large sliding doors in the side of the building will be drawn back, so that persons can easily pass from one to the other, and the two structures will be, for all practical purposes, the same as one building. By this means the amount of space available for exhibition purposes will be doubled. There will be a broad walk down the middle of this tent, and a stage on each side for the various collections which it will contain. Then, in addition to this, there is in the course of erection another structure, at right angles with the other two, running past their ends, and extending far beyond them. This consists of a wooden frame-work, covered with canvas, and is of the same width as each of the other two, viz., 60 feet, and is 300 feet in length. The internal arrangements of this wing are somewhat similar in style to that adopted for the great international show in London last year, and consists of a series of grass banks and gravel walks. The 300 feet are divided into six equal portions, and in the centre of each of these a circular mound is thrown up, some six or seven feet high, with three tiers or stages, all covered with green turf. These are surrounded by a gravel

walk 12 feet in width, and on the other side of this walk more grass-banks of two tiers or stages, extending the whole length of the building.

It will be understood from the above description that the general form of the show will be something like the letter L, and it will be evident to the reader that a person standing in the angle thus formed would be able to see the whole length of both wings without changing his position. This circumstance has been taken advantage of, and an artificial mound has been made some 12 feet high, over the top of which the broad walk, which runs through the tent first described, is made to wind in its way to the grass banks in the other wing. From the top of this mound the whole of the exhibition will be seen at a glance, and will no doubt present a very imposing appearance. Orchids, and the more tender stove plants, will be placed in the exhibition house. Fruit, vegetables, and cut flowers will be arranged in the tent at the side of the building; and the larger specimens of flowering plants, ferns, and ornamental foliage, will be staged on the grassy shelves which surround the mounds in the long wing. The place of exit from the exhibition is so placed that the visitors on emerging from the building will find themselves on a broad gravel walk, which surrounds the flower garden, situated on their left hand, and a lake of water with its islands and ornamental bridges on the right. The various ranges of hothouses, greenhouses, &c., together with the lodges and entrance gates, are all being repainted for the occasion, which, so far as I could gather, is likely to prove a great success.

THOMAS JONES.

THE MOST BEAUTIFUL WILD FLOWERS: WHERE TO GATHER AND HOW TO CULTIVATE THEM.

Few people have any idea of the number of really beautiful plants that are natives of the British Isles, and even those who study the subject to some extent rarely regard them as garden plants, or, remembering that our pinks, carnations, &c., have come from native plants, ever look among the large number of species inhabiting the British Isles for an addition to the charms of our gardens. Botanists know a good deal about wild flowers, to be sure, but as botanists rarely or never cultivate them, they can add but little to our knowledge in this way. One difficulty in the way of acquiring knowledge of them [is the fact that few have an opportunity of seeing a great variety of our wild plants; the Londoner has within his reach, or within twenty miles, as fine a collection of lowland plants as any in Britain; but then he rarely has an opportunity of seeing those of high mountains, or those of the west of Ireland, and *vice versa*. It is only by a careful selection of all the plants in the British flora that you can get good material wherewith to make a pretty and interesting "English garden;" and that such would prove a charming addition to all but the very smallest places, I venture to submit. We all know how slowly the study of botany progresses amongst us. May it not be attributable to the fact that we never approach the subject in any way but the cut-and-dried, so to speak? We collect a certain number of species, flatten and dry them, and in due course leave them by and forget them, never deriving anything that might be called pleasure from the study of our British wild flowers. Why should not a tasteful amateur or gardener take pleasure in preserving in good health the rare and beautiful *Gentiana verna* of Teesdale and the western shores of Galway,—one of the prettiest things ever seen,—as well as a native of the Cape or Australia? Need we grow weeds to have a fair representation of beautiful British wild flowers? No such thing! It will be my pleasant task to look over the whole British flora with the reader, to tell him where to find and how to grow the rarer kinds, and to enumerate every one that is really good; and in doing so I shall have to name a great variety of plants, but not one weedy subject I hope. This is the season of wild flowers, when most of us stray into the fields, or on to the hills, to find many a gem which I advise should be grown in the garden instead of being put in what we may call pickle. You may have heard of a little plant named after Linnæus. I have a lot of this now growing under a painted hand-light in peat, as well as in pots stood in saucers, and kept in a shady place; and it is this very plant that has induced me to begin what I often thought about ere this. It has been my fortune to grow most of the really good plants in Britain, and I am not without hope of being able to convey some original information about them.

The first plant to which I shall introduce the reader is this *Linnæa borealis*, a native of fir-woods in some of the eastern counties of Scotland, and therefore difficult for most people to obtain in a wild state; but being a great favourite with lovers of curious plants, it may be had in some nurseries, and not a few private collections. It has been named after the great master of natural science, with whom it was a special favourite, on account of its native beauty. It is of the easiest culture. Grow in pots of peat in a cold frame, or plant out in peat and cover with a hand-light which is darkened, or rather daubed over with paint, if you happen to live in a very hot and dry locality as to soil or climate. Growing in woods in northern regions, it is fond of shade in cultivation. I have seen fine specimens grown in pots, and large pans of peat, kept behind a hedge or high wall in summer, and placed in a cold frame or pit in winter; and I have also seen it grow freely planted in a little artificial peat-bog in the garden of the late Mr. W. Borrer, in Sussex.

Most worthy of notice, in the Stellate or Galium tribe, is the

little white-flowering Woodruff (*Asperula odorata*), which bears its white flowers profusely in many British woods in spring, and I have seen it flowering very abundantly among the trees and shrubs round some of the colleges at Oxford. It should be known to every garden, in consequence of the sweet smell it yields when dried, and when kept for a long time, preserved in drawers, or aught else. There is no plant more worthy of culture for this purpose alone, the dried stem being as fragrant as the sweetest new hay, and continuing to give forth its odour for a long period—an indefinite one, so far as I know. It is fond of slight shade, and worth planting where not found in a wild state. When green, the "haulm" of this plant betrays no noticeable fragrance, but begins to emit it very soon after, and merely requires to be placed on some dry shelf or half-open drawer, where it may become quite dry and ready for use.

The common Red Valerian, as it is called, or *Centranthus ruber* botanically, is a really ornamental garden plant, and makes a conspicuous ornament for banks, borders, or large rockwork. As it may be readily raised from seed, there can be no difficulty in procuring it, and it should be noted that there is a fine deep red as well as the ordinary variety, and also a pure white, and all the three are really ornamental plants. Their best use is to stud here and there among diversified or sloping banks, in the English, or gardenesque, or natural, or whatever-you-like-to-call-it style of laying out grounds. Like the wallflower, it does well on old walls, &c., and thus has become "naturalized" in many parts of the country. It is the first plant that occurs wild in newly-opened chalk pits.

The composite or Dandelion family is generally so ragged in appearance, that I scarcely like to introduce it here. Some members of the family are so commonly seen wherever we walk abroad, that the greatest care must be made in selecting garden subjects from this order. The Hieraciaceae are in some cases showy and fine plants. Here I will merely mention *H. aurantiaca*, a neat border plant, and distinct in colour, and pass on to *Carduus marianus*, the milk thistle; *Carduus eriophorus*, a noble thistle, found chiefly in the limestone districts of the south of England—to the great woody, silvery cotton-thistle, or Scotch thistle, as it is often called. Though these come near the thistles, and are anything but a gardenesque family, no reader need be afraid of introducing them to his garden, to which they are sure to add distinction, especially now, when people are beginning to notice more plants of noble or distinct form and habit. Though frequently selected as the thistle of Scotland, it is not a native of that country; so the Scotch thistle is a more dubious vegetable than the Irish shamrock. But, Scotch or Scotch not, if you search the whole vegetable kingdom, you will not find among plants that are at home in our climate anything more distinct than this cotton-thistle, or *Onopordon acanthium*. A single specimen, standing in the midst or in front of green shrubs, produces a noble effect, and the plant should be in every garden. Easily raised from seed, and once established in a garden, it sows itself. Then the precaution should be taken of thinning down the young seedlings, or you may have far too many of them. One isolated plant or a group or two is quite sufficient for ordinary gardens; but where there is sufficient space, it, with many other fine wild plants, might be naturalized with great advantage by simply sowing a few of the seeds in any waste or half-wild spot, or in the shrubbery. The milk thistle, with its shining green leaves and white markings, is also very desirable among the British plants, though scarcely so much so as the great cotton or Scotch thistle.

Everywhere the common corn-flower, *Centaurea cyanus*, makes a beautiful garden plant, if sown in autumn and allowed to flower with all its accumulated vigour in spring. Sown in spring, it is far inferior. I know of nothing more beautiful than a large group or small bed of the various coloured forms of corn-flower in full bloom in spring and early summer; the bloom is so prolonged and vigorous, the flowers so pretty and so useful for cutting for the usual purposes of cut flowers. It is common, and easily had from any seedsman. One of the prettiest of all dwarf trailing silvery plants is the Tomentose *Diotis maritima*, which is found on the southern shores of England, coming up as far as Anglesea on the west and Suffolk on the east, but generally a rare plant in this country; it may, however, be had in nurseries, and is worthy of a place in every garden, and especially in every collection of variegated or silvery leaved plants. The common Tansy is too coarse a weed for any but the herb ground, but there is a variety with leaves cut into numerous segments, and crisped up as elegantly as the New-Zealand *Todca superba*, and this should be provided with a nook, its flowering stems requiring to be pinched off when they show. The name of this tansy is *Tanacetum vulgare crispum*. The double variety of *Pyrethrum*, now so frequent in our flower gardens, is a native plant—or, at least, the single or normal form of the species is. The sea wormwood (*Artemisia maritima*)—is a neat silvery bush, freely distributed on our shores, and worthy a place in our gardens. There is a deep rose-coloured variety of the common Yarrow

(*Achillea millefolium roseum*)—pity one cannot avoid those hard names—which should be in every garden, and there is a very pretty double white variety of the “Sneezerwort” (*Achillea ptarmica*), which will be found highly ornamental. At Paul’s Cheshunt nurseries I noticed them cutting it extensively for wedding bouquets, during the past summer—the flowers are so purely white and neat. Perhaps some of our readers may regret that I do not give the English names of all plants, and that I do not explain by the fact that they have no English names in a great many instances; and would it not be a foolish barbarism to invent them, or to give awkward translations of the Latin names? Many people have an idea that every plant has, or should have, a “common name,” whereas such only belongs to plants that have been much noticed by the people either for their beauty or “vertues.” Now, as hundreds of plants are so inconspicuous, or so rare that they were never noticed till the sharp-sighted botanist took them up, and gave them a Latin name, which is on the whole the best, because the language is fixed, and common to the learned of all countries, it will be readily seen why we have not English names for all our plants. However, the next member of this natural order *compositæ*, or the daisy order, which I shall notice, is endowed with several common names, respectively, “Mountain Cudweed,” “Cat’s Ear,” and “Mountain Everlasting”—the botanical one being *Gnaphalium dioicum*. It is a beautiful dwarf plant, admirable for rockwork or the front of a border, or in any way amongst alpine plants. Abundant on mountains in Scotland, Wales, and many parts of England. There is a variety called *rosea*, to be had in some nurseries, that has its dwarf flowers delicately tinted with rose; a most desirable thing. I have noticed a neat edging made of this plant in Dickson’s nursery at Edinburgh; so that Scotch readers will have no difficulty in procuring the plant, even if they cannot find it wild; but it is a popular plant wherever alpenes are grown, and therefore not difficult to obtain anywhere. The “pearl condensed,” or *Gnaphalium margaritaceum*, is a popular old plant in gardens, its flowers having been often dried for everlasting, and altogether it makes a respectable, though not first-rate, border plant, and should be in the “garden of British wild flowers.” So much for this great natural order *compositæ*. I might have selected a few more, did I not wish to avoid weeds as much as possible.

We will now turn to the extensive Harebell order, where we shall find much beauty with little or no raggedness—from the harebell, which swings its bonny blue flower above the blast-beaten turf on many an upland pasture, to the little prostrate ivy Campanula (*C. hederacea*), which is rather plentiful in most spots in Ireland and Western England. The giant Campanula (*C. latifolia*) is one of the handsomest, and is pretty frequent. The spreading Campanula (*C. pabula*), of the central and southern counties of England, is also very ornamental. *C. Trachelium* is also good, and indeed nearly all the members of the family are of a character superior to that of most of our wild plants; but none of them surpass in beauty the common harebell, which, although it may look struggling for existence, and comparatively poor as regards the plant, on exposed pastures and elevated spots, yet when transferred to a garden it makes a vigorous plant, and flowers profusely—a mass of pleasing colour. It is capital for the border or large rockwork. The little Ivy Campanula had better be grown in a pot of peat soil, or in some moist and slightly shaded spot where it may not be overrun by tall plants. If you grow it in a pot, stand that in a saucer of water, and then the tiny ivy-like shoots will fall down over the edge of the pot, and when dotted over with its pale blue flowers will look very interesting, especially to those acquainted with our native plants. Both this plant and the even more interesting *Linnaea borealis* may be grown well on the outside of the window, with a north or shady aspect during the seven warmest months of the year, by planting them in pots of peat earth, and standing in pans of water. In winter they would be better placed in a cold frame or pit. To be able to cultivate things so interesting to the botanist, and to all who know plants, as these are, would surely be more gratifying than any amount of such subjects as we see displayed in every window.

In my next paper the beautiful Heath family will be discussed; so now I will say good day for a week or so, and sign myself—and I am sure many readers will be glad to find there is as yet an individual of the species living in a wild state in England—

CYPRIPEDIUM CALCEOLUS.

PLANTS THAT SHOULD BE PROPAGATED FOR WINTER FLOWERING IN THE STOVE.

The gardener’s mind, in connexion with his occupation, may be said never to be at rest, as he must be constantly exercising his faculties in endeavouring to provide for the future. Long ere the flowers of summer have suffered eclipse of their lustre, the propagation of plants for winter decoration must have his immediate attention—that is, if he is anxious to have all prizes and no blanks, by seeking to maintain a succession of flowers throughout the

year. Perhaps there is not so much difficulty attending the labour as many imagine; perseverance must be the motto, and a host of hitherto conceived difficulties are swept away before you.

We will begin our list with the most useful and showy of all the species that adorn the stove during the late and early dreary months of the year, namely, *Poinsettia pulcherrima*. This plant will submit to very liberal treatment during its growing season; it is a mistake to continue to force its growth by the aid of artificial heat from the time it commences to grow till it flowers. The finest plants, and showing the finest bracts I ever witnessed, were in a house containing some fine specimens of other kinds, cultivated by my esteemed friend, Mr. W. Monk, then gardener to the late — Drewett, Esq., of The Cedars, Tottenham Green; and I wish he would kindly favour us with a paper on their treatment, as such would be a boon to the readers of the GARDENER’S MAGAZINE, who have an interest in their cultivation. His mode of culture was to pot them into very large sized pots as the season advanced, and train them into large specimens. When they became pot-bound, or, in other words, when the pot became filled with roots, he gave them a top dressing of sheep’s manure. This not only imparts strength to the shoots, but gives to the leaves a very dark healthy green hue. They were kept growing without the aid of fire-heat during the warm months of the year; of course, as soon as damp cold nights occur, they must be assisted with fire-heat, or the chances are a great number of the leaves will turn yellow; besides, a cold moist atmosphere would tend to injure the future flowers. This is about the most favourable time to propagate them. This can be done by cutting off the ripe shoots of any plants that have continued dormant from the time they have flowered up to the present, into lengths of two joints, and inserting them singly into thumb-pots. If you have abundance of cuttings, why, you may put three cuttings into large 60-size pots. Plunge them in bottom heat, and keep the soil from getting parched, but otherwise do not give them any water till they have begun to root in the soil. As they require more room, continue to shift; and should they be inclined to become lanky, stop them, and that will induce a bushy growth; but do not defer this operation late in the season, or your blooms may become small, as the future shoots will not have sufficient time before them to gain strength. Any of the points that you may pinch off can be treated as previously recommended, and they will become nice single-stem plants for decorating the hall or dinner-table. If you have room for them, you cannot cultivate too many of this beautiful flower, as they last a considerable time, especially if they do not suffer from damp. After they have done flowering, they can be stored away in any dry corner of the stove, or any other house where the minimum temperature is not below 50 degrees.

Euphorbia Jacquinæflora.—This plant is deserving of all the pains that can be bestowed on its culture. Its countless scarlet spangled-like flowers, clothing a tall but slender stem, produce a brilliant effect. It will submit with advantage to be trained to a trellis, and will not bear to be treated so roughly as the *Poinsettia*. The soil requires to be more porous, and to be afforded plenty of drainage, as it quickly suffers from an excess of water to its roots. It will strike freely under a bell-glass, having a joint of the old wood attached to the young shoots, the cuttings being inserted in a prepared pot of soil, with a surface of about an inch or more of silver-sand.

Eranthemum pulchellum.—The colour of the flowers of this plant, being a lively blue, makes it very acceptable as a change among other winter-flowering plants. It is best to provide a succession of young plants every year of this variety, it being a free grower. Plants may be struck now, and after they have rooted should be pushed on rapidly and stopped when required; thus treated they will form some pretty bushes by the period the flowering season commences. Old plants are very subject to be attacked with scale and other kinds of insects, and it is with difficulty they are cleansed of them, if ever thoroughly.

Justicia speciosa.—A very free-growing plant, the colour of the flowers being of a purplish blue. It is not so showy or so desirable a plant as others in this list. Plants now propagated will grow very fast.

Begonia Digswelliana.—This plant, for winter flowering, will become a universal favourite as soon as our gardening friends become acquainted with its merits. It produces clusters of beautiful light-pink flowers, excellent for cut flowers.

Begonia nitida.—A good old useful variety, though not equal to the last-named, its habit of growth being rather straggling.

In addition to the above short list, propagate some of each of the following for forcing and conservatory decoration, viz.:—*Salvia splendens*, *Salvia gesnerifolia*, and Pelargoniums *Alba multiflora*, *Snowflake*, *Gauntlet*, and *Brilliant*. I could extend this list, but my desire is to name only the most useful subjects, leaving lovers of mere curiosities to find out what may be added to the foregoing selection of subjects, that are everywhere indispensable.

JOHN F. M’ELROY.

HEATING A SMALL GREENHOUSE.

Allow me to make a few remarks upon heating small greenhouses, a subject occupying much attention just now. I have a small house, say 17ft. by 11ft., which contains nearly 400ft. of glass; I name this because I believe the quantity of glass ought to be taken into consideration with regard to the power of your heating apparatus. Until lately my house has been heated with hot water; but during the severe frost I found it quite inadequate to my wants—not that I could not get heat enough, but because of the great amount of attention required in stoking to get it. The boiler I used is a saddle boiler, with a small flue only, requiring one shovel full of slack for each feed, and requiring attention every hour or hour and a half; and during the late frost, being my own stoker, I sat up most nights until 12 o'clock, and then hap'd up the fire the best way I could; but the draught being strong and a small body of fire, I rarely succeeded in keeping it in many hours; and one of my bad practices, which I had better own to, is being a late riser, which gave the frost an opportunity of taking possession of the house for some hours in the morning, killing several of my plants and injuring many more. Finding my heating apparatus unsatisfactory, I resolved to make an experiment by uniting a gas-stove with hot water. The apparatus I got made of tin, costing me only a few shillings. This has quite answered my expectations, the stove being hot in a few seconds after lighting the gas, the water-pipes in about one hour after. My apparatus being made of tin, will not stand forcing. The stove is perfectly simple though effectual; a sketch of which I subjoin. Should any of your readers who are similarly situated to myself wish to try it, they would, I am sure, find it act satisfactorily; and there are hundreds of small houses near towns and villages now supplied with gas, which might avail themselves of it, and thoroughly abolish stoking. The stove I have now in use at so small a cost is not quite

Fig. 2.—Section of stove and air chamber:—1, Gas-burner with wire-gauze. 2, Air-supply pipe. 3, Flue through the boiler for hot or burnt air. 4, Conductor of hot air to top of stove previous to its exit. 5, Hot-air chamber. 6, Escape-pipe for burnt air.

perfect; yet it does its work well with about 6 feet of gas per hour, and kept the house at between 40° and 50° when there has been several degrees of frost outside. This, I suppose, may be considered a good test. The average price of gas with us is 4s. 2d. per thousand, or say 5d per 100, so that twelve hours burning would consume 72 feet of gas, at a cost of 3½d. Good slack with us costs about 4d per cwt., and I find twelve hours stoking will nearly take one cwt., so the price of gas in small houses would not exceed that of coal. There is no unpleasant smell with the stove, as it supplies itself with air, and every crevice might be closed against the issue of burnt air into the houses, and the stove still perform its work effectually. I believe gas will come into general use for small houses, where parties are acquainted with the best way of using it; but I do not go so far as Mr. Clark, to think gas will be universally used in large establishments. First, because they do not suffer the inconvenience of a person with one small house, as where a number of men are kept one might safely leave the flues holding a great body of fire at 12 p.m. until another arrived at 6 a.m. Secondly, it must be borne in mind there is a great waste of heat in manufacturing gas, taking one ton of coal in the furnace to cook another ton for abstracting the gas, and which heat might be beneficially applied in large houses. To this add labour of making gas, management and interest upon capital, which must act against using gas in large quantities where the raw material can be beneficially applied. But to a person growing a few plants for amusement to be bored with the same or more trouble in stoking than if he had a couple of large houses heated with one flue, and particularly if occasionally called away from home on a frosty night, leaving the house to the mercy of the weather, acts as a drawback to many who would have great pleasure in growing plants. I think to such the combined stove would offer a fair inducement to cultivate plants.

I had almost forgotten to add that there is one thing necessary in lighting the stove, which is common to all gas-stoves, that is to light the gas as soon as turned on, or it will fill the stove and cause a small explosion.

I beg to say I have no interest in writing this, further than to offer to others what has been a great benefit to myself.

B. WILSON.

Ilkeston, near Nottingham.

Since the foregoing was in type, we have received from Mr. Wilson the following, dated May 16, 1867:—

I would also beg to observe, I have continued to test the stove until last week, when I removed it from the house, and it has more than warranted what I have previously stated. Being an experiment only, there was no aim at embellishment. The latter part of the time it was in use I removed the air-pipe, No. 2, and found the stove to act quite as well without it. In fact, in the first case I had some misgivings as to using

Fig. 3.—Bird's-eye section.

gas amongst plants, and felt inclined to seal up every crevice where burnt air might issue into the house. I now find by doing away with the pipe the stove draws a slight current of air from the house, which is easily perceived by holding anything very light near the opening; which current, I think, improves the air and keeps it from being stagnant, as my plants have been extremely healthy since I used the stove. There is not the slightest smell of gas or burnt air perceptible in the house; so I conclude the air-supply pipe is not necessary. Several other improvements might be made: I am not speaking of the appearance, but the principle. First, a very small portion of gas in a few seconds greatly heats the air chamber, which might be extended to double the size. This would give a greater heating area, by simply adding a flange to the top of the boiler, leaving the boiler the same size as at present, and cased with ornamental grating to range with the air chamber. The stove as at present is entirely made of tin, and requires attention to turn the gas on sparingly, or the tin melts.

Sketch of burner used. It is covered with gauze, the cross being of copper wire turned up at the ends and stuck through the gauze to hold it on, and which appears to want replacing about once a month, at the cost of 1d. and two minutes' trouble.

This does not alter the principle, but delays getting up the heat as quickly as might be. The hot-air chamber instantly throws off heat as soon as the gas is lit, but it takes one hour before the water-pipes get hot with my present stove, and from two to three hours for the pipes to reach 150 degrees. In reaching this heat it is inclined to throw the water out of the feed-pipe, No. 10, it being too small and of wrong construction for a permanent stove; but with a copper bottom to the boiler and iron air chamber, and the feed-supply enlarged, there is no fear for the result. A few gentlemen who have seen it in use can hardly believe the heat to arise from so small a plaything. Having a test-meter at command, which I have attached, I find I can burn six feet of gas per hour—one foot more interferes with the tin. Should the stove ever be manufactured in a permanent and ornamental manner, I shall certainly purchase one as a fixture, in preference to hot water, which I have previously heated with.

B. W.

Fig. 1.—The stove, as at work, made in compartments, can be turned to suit convenience:—1, Stand. 2, Door to light the gas. 3, Boiler. 4, Heated-air chamber. 5, Heated-air escape pipe. 6, Gas-supply pipe.

7, Air-pipe. 8, Hot-water pipe. 9, Hot-water return-pipe. 10, Feed to supply water. 11, Air-pipe.

NOTES OF A TOUR THROUGH KENT.

A VISIT TO KNOWLE PARK, THE SEAT OF THE EARL DELEWARE.

I commenced my annual rambles for my customary visits to good gardens on Thursday, May 8th; and certainly I never remember starting with more favourable weather, or with a better prospect that I should be delighted with what I saw. The morning was serene and beautiful, and all nature was alive; and those members of the vegetable kingdom that had gone through the winter season, bereft of their usual leafage, were gay with charming tints of lively green, that added much to delight the eye and to make the mind feel grateful for the return of spring. As I left the populous suburbs of the great and busy city, the charming fields on the right hand and on the left were clothed with their first flecks of summer colouring; and as the powerful locomotive with its angry groans hurried us onwards, through open fields and extending breadths of a fertile country, we felt lifted, if I may so express myself, in an infinitely short space of time from the depths of a long and cruel winter to a state of exuberant delight, such as doubtless every lover of nature must feel when he finds himself surrounded with all that is beautiful and good—good, because exemplifying in the most instructive manner the presence in the midst of nature, to control, fashion, and bless, of an All-wise Creator. The mind that neither appreciates nor studies the various phases of the different seasons can never correctly value those beautiful works of nature that surround us on every side in the spring of the year, and indeed in all seasons. However, such were the agreeable conditions under which I arrived at the delightfully situated town of Sevenoaks, in the close vicinity of which is Knowle Park. Indeed, the principal entrance to Knowle is out of the main thoroughfare or street at the top of the town. But having

find the respected head-gardener, Mr. James Dodds, whom I had no sooner shaken by the hand than he evinced great pleasure in showing me the many beautiful sights of Knowle.

Crossing that portion of the park that divides the kitchen gardens from the pleasure grounds, our friend pointed out several noble oak trees, from which, in his opinion, the town of Sevenoaks originally derived its name. In this, of course, there is some amount of conjecture, as there appears to be no authentic information on record of the existence of any other at the time that the name of Sevenoaks was applied to the town. But the immense age of these trees, which are, strange to say, seven in number, and apparently about the same age, and at no great distance from each other, is quite sufficient to justify the opinion of our friend, more particularly when it is known that the existing seven trees in another part of the town bear so young an appearance. That the alleged etymology of its appellation is very questionable when applied to these younger trees there can be no doubt. We now enter the pleasure grounds, 35 acres in extent, the whole enclosed by a wall and that portion of the mansion that forms the boundary line of these 35 acres. The house covers five of them, and the park which surrounds it is 1000 acres in extent, well stocked with deer; but the absence of water in sufficient breadth is the only defect that can be noticed in the many otherwise magnificent features of Knowle. It is impossible for me, in the compass of these notes, to do full justice to one of the finest baronial residences of England; but it will, I hope, suffice if what I say stimulates the admirers of the venerable and the grand to go and judge for themselves of the gratification to be derived from a visit to one of the gems of the county of Kent. Having entered the pleasure grounds by what was formerly called the Tunbridge Wells entrance, the scene is at once unique and grand. On the right hand and the left are huge

ROSE GARDEN AT KNOWLE PARK.

HALF-STANDARD ROSES.

WALK.

WALK.

HALF-STANDARD ROSES.

arrived opposite the church, I was unable to decide which of the two entrances that were before me was the one I wanted, as, having no guide or proper directions, the one that had the most pretensions certainly seemed to be the proper one. But in this I was mistaken; for Knowle Park is entered only by a very commonplace carriage drive and gates, without a lodge, or indeed anything that would lead a stranger to suppose it was the entrance to so noble a place. But having entered, the traveller soon forgets what he has left behind, for he at once plunges as it were into a beautiful forest of trees, which not only affords shelter and shade, but gives a character and a sort of foretaste of what is to come. Such, however, was the impression it made on my mind; for, when coming out of this noble bower, there lay to the right and left such a charming valley, with noble belts of trees gracefully dipping their branches down to a verdure of unusual richness, that instinctively I felt arrested in my progress, and stopped to gaze at the majestic scenery before me. The characters here are so bold, so full of harmony, and above all so judiciously placed, where the art of man has been brought into exercise, that I say without any fear of contradiction they are not to be excelled, if equalled, in any part of England. Those who may feel disposed to question the propriety of this remark, must remember that the beauties of Knowle belong to itself alone; for it is not dependent in all these immediate effects upon the surroundings of other properties. I now start to ascend the hill on the opposite side, full of delight and gratitude that I am allowed by the noble proprietor to share with him for the time being the enjoyment of such classic grounds. Taking one of the three paths that present themselves at the foot of the hill, I make the ascent, and here again enjoy the shade of another avenue of trees, upon reaching the skirts of which the noble mansion stands out in all its grandeur before me. Thus far I had enjoyed the walk towards the gardens alone, because it was on my way to

banks of rhododendrons, some eight to nine feet high, well set with bloom-buds, and evidently in a most luxuriant condition in the natural soil of the place. These banks run on either side of a straight moss-covered walk the whole width of the grounds, extending, I should judge, fully a quarter of a mile in length, and when in flower, which, from their shady position is somewhat late, must make a striking effect. But there is still a grander feature presents itself at this spot. Immediately on entering, the eye is carried down a charming green drive of ample width, and towering up on each side are well selected varieties of stately trees, and beneath them a cheerful undergrowth, that gives to the whole place a character of repose united with grandeur; for below in the distance, as the eye is carried through this mighty bower of stately trees clothed with the fresh hues of summer, one of the private entrances of the mansion is seen in its quaint and unpretending character. The effect of this view is such that one feels the imposing characters of the place are in strict keeping with all that surrounds it. My conductor now took me for a charming ramble beneath towering trees and through groves of unusual richness, until, by the abrupt turning of a walk, we came unexpectedly upon a large body of rockwork. This, although not showing any of the bold characters that would be considered in the present day essential in such a conspicuous feature, was nevertheless quite in keeping with the surroundings of the spot, and as it is not the work of yesterday or to day, we may conclude that it is a fair representation of the prevailing taste in such matters at a period long since past. But although formal in outline, and deficient of those rugged and irregular characters that are looked for in rockwork, the hand of Nature had done her work in an admirable manner, as every crevice and projecting nook was beautifully clothed with a rich and varied surface of living specimens of such members of the vegetable world as delight to ramble on such spots, besides those that

had spontaneously made it their stronghold. The hand of the gardener had not been idle, as a hountiful show of ferns and other rock plants had been added. Going more in the direction of the mansion, we came upon some extensive plantations of the more choice varieties of rhododendrons. Some of these were brilliant in colour, and very effective—in fact, the beds are so well distributed amongst other masses of luxuriant foliage, that their massive flower-heads contrast conspicuously against the refreshing green of the adjoining trees. A short distance from this spot, but still near the mansion, is the herbageous garden, in which there are many rare and good old favourites. The contrast between this spot and that of another, which has just been laid out in a very ornamental style for the reception of the more choice kinds of bedding plants, would surely be sufficient to convince every advocate of the bedding system that, when so vigorously standing up for their own favourite hobby, they are ignoring the existence of many truly valuable plants, which, in their anxiety to be fashionable, they lose sight of and despise because they are less gaudy than a Mrs. Pollock geranium or Foxhunter verbena. Near the above spot we saw many fine examples of Conifera in different varieties, and the unusual luxuriance of many trees and shrubs of like character speaks much for the fertility of the land. Indeed, in whatever quarter we look, the same luxuriant growth meets the eye. While enjoying the quiet of this spot, and desiring to linger and enjoy it, my worthy pioneer, pointing southward, arrests my attention, and with all speed I follow him, wondering when these delightful surprises are going to end; for, indeed, there seems to be no end of them in this beautiful place. But this time my friend did not reckon upon the character of his visitor, for he did not seem to think I should care to inspect a clump of trees of ancient date; so he was hurrying me onward to the south-west corner of the grounds. But, in passing, my eye caught a perfect circle of lime-trees, feathered and drooping gracefully down to the ground. This sight I could not pass unnoticed. This is called the Lime Circle. The arrangement of the trees is shown in the following sketch, the black dots denoting where the trees

stand. The outer line is intended to show the extreme ends of the branches, which droop down to the ground. I cannot venture to guess the age of these trees, but they have evidently stood there many centuries. There is only one way to get to the centre, unless the branches are lifted on one side. Once inside, you are free from the prying eyes of any one outside; and when I say that the outside circle is 120 feet across, the reader will judge that the space beneath is equal to supply room sufficient for a good round number of a picnic party. I do not so particularise this clump of trees with any wish to overrate their value in a decorative sense; it is simply to show the good taste, the superior foresight of the designer of these grounds. Nor do I refer to this particular instance to show the excellent judgment displayed, because in every part of these noble grounds the same degree of care, the same amount of foresight has been exercised, and some of the most beautiful combinations have been effected that only a long course of years could bring about. We are often led to express a favourable opinion (not undeserved, perhaps), when we gaze upon some well-arranged flower garden, or some exquisite blending of colours; but these are as nothing when compared to the majestic features that time and judicious planting have secured in so many instances in Knowlton Park, and which not only enhance our pleasure in viewing the place, but teach the interested observer to set a just value upon the services of those who were engaged in creating so many objects of beauty for our special use and learning. True, it may be said that the landscape gardener, when arranging the various scenes of planting, was greatly favoured in his work by the undulating surface of the grounds, which, so far as I have yet seen, are unequalled in this country.

But while admitting this, I am bound to acknowledge the superior skill of the designer, and the discriminating use made of the subjects brought into requisition. On every hand were evidences of the good judgment that had governed the selection of trees, for their various characters of boldness, grace, or massiveness of outline; so that at last the impression grew upon me that in the midst of these splendid effects the master-mind of the planter stands boldly forth as a beacon that ought to guide us in this present day, when engaged in planting. In proof that I am not overstating the case, I will refer to the north-east corner of the pleasure-grounds, where there is a break in the wall of about thirty feet wide, which also occurs in portions of the grounds. I remember we reached this spot by a circuitous path, and standing on a slightly elevated position, we have at first before us a fine stretch of undulating pasturage reaching down into a valley below; and beyond, rising in the distance, standing out in bold and broken outlines, is a well-wooded portion of the park. The innumerable tints of the foliage of these trees, supported as they are by a background of forest plantation, chiefly of spruce and Scotch fir, give to the whole view before us an aspect of majestic splendour; and all this is secured within the limits of the grounds, without help from beyond. This must be sufficient to convince every interested reader that I have not drawn upon my imagination to give to this place a character it does not possess. Indeed, it

would be impossible for me to do so, for as I write I feel that my efforts to do it justice, although sincere, are by no means equal to the task. Mr. Dodds now shows me, from the south-west corner, another delightful view of the park. The surface here is quite as undulating as any we have seen; but it is from this spot especially that the absence of water to any extent is somewhat felt, as the eye would feel a relief by its presence. But there are sufficient attractions, and sufficient to please the eye and instruct the mind, without the presence of this useful element.

We now direct our steps towards the house, and in a quiet corner of one portion of the grounds adjacent to the conservatory we find the rose-garden; a plan of which I give, with a view to show the rapid advances made from straight lines to friezes and scrolls in the present day. The plan, as shown, consists of twenty-two long beds, three feet wide, with narrow walks between. On each side, and extending the whole length of the garden, is a long bed the same width as the others. These two beds are filled with half-standard roses, and all the cross beds are filled with dwarfs upon their own roots; the whole of the garden is laid down in box edging, and the walks with gravel. Although the reader may think the plan stiff and formal, it must be granted that, for convenience of attending to the beds, it is superior to many laid out in the present day; and as to what other objections may be raised against it, we should not forget that, even at this date, its straight lines and formal bearing is in great part quite in keeping with the character of the whole place. A short distance from here, in what was formerly an old fruit garden, Mr. Dodds has designed, and laid out in a most tasteful manner, a new flower garden, and which, when well established, is destined to prove a grand feature in the place. I certainly feel it my duty to publicly thank Mr. Dodds for the spirit he has shown in stepping on one side of the laws which are said now to guide the designer in these matters. For while we too generally see an elaborate design with innumerable flower-beds crowded into a small space totally unfit for it, and where, owing to the beds being in close conjunction with each other, the colours cannot be detected when looked upon at a few yards' distance, Mr. Dodds has had the spirit and the good taste to secure sufficient space between his beds, that, whether looked upon from far or near, they must remain sufficiently distinct to enable the observer to detect each separate colour; and this is secured without showing more of the groundwork or body of the plan than is required to create a distinction.

Upon a southern wall that extends 140 feet along this flower garden, the *Wistaria sinensis* covered the whole length, in fine condition, just coming into bloom. As we stand on one side of the private entrance of the mansion, we observe the conservatory and camellia house, 100 feet long, filled with noble subjects, and on the other side is the orangery, of the same length. This noble structure, we were informed, was suggested by the late Mr. Loudon. At one period, I believe, this structure was nothing but a sort of workshop; but, thanks to Loudon's wise suggestion, it is now a noble ornament to the other parts of the building: it is filled with suitable subjects, all in the finest condition; indeed, many of the trees were literally covered with fruit of no mean size.

Tracing our steps back to the gardener's cottage, we now enter the kitchen garden and forcing department; and first we find a range of five houses, the centre being a plant house, with vinery and peach house on either side. In the plant house we find a well-grown useful selection of plants, and in the vineries the vines, although old, are in a very good bearing condition. In one of these houses my friend had carried out the extending system very successfully under the circumstances. The peach houses were both newly planted last year, and looked very promising for a crop for future years, as they were making a vigorous growth. In a separate structure, used principally for stove plants, we saw a various selection, and amongst them a *Passiflora Buonaparti*, with stout leathery green leaves three inches long, the petals dark maroon colour, and the inner segments of the centre are like whorls of white and purple; it is in the way of *Passiflora alata superba*, only rather darker both in foliage and flower, and more vigorous. In several ranges of pits and other structures, large quantities of bedding plants in good condition. The number of bedding plants required here is about 12,000. The extent of the kitchen garden is about four acres, of a fine mellow loam, well stocked with all the subjects essential for the supply of a family, and scrupulously clean. Upon the wall I noticed more than an average crop of apricots, which our friend told us has been every year better since he left off covering up the trees while they are in flower. Our readers should take note of this remark, because this is not the first instance where a like result has been attained by the omission of coverings while the trees are in flower. Neither peaches nor nectarines are grown here upon the open walls, as they are found not to do well; but both pears and cherries are remarkable for their luxuriance, and this year there is every prospect of a heavy crop, more especially of cherries, for the Morellos and May Dukes are literally covered with the fruit in its first stage of growth. I had pointed out to me a remnant of an old May Duke cherry-tree that had been planted 70 years; it is now in excellent bearing condition. I saw also excellent crops of the Bigarreau cherry. Of strawberries there is generally speaking a fine prospect of a crop this season. In this place the most useful sorts are found to be Goliath, Elton Pine, and Keen's Seedling.

This must conclude my notes of this delightful place; and although they have extended to some length, I cannot say that they convey to the reader a correct idea of every thing that may be seen at this enchanting spot; but, as a sort of set-off against this, I may state that the mansion is open to the public three days in each week, so that those who may desire to learn more of the beauties of this place than this brief description conveys may see for themselves. In closing, I can only say my visit to Knowlton will ever remain a bright spot in my remembrances of good gardens.

J. C. CLARKE.

ON AMARYALLIS, AND HOW TO GROW THEM.

I have often been asked the question by a lady or gentleman, on going in their greenhouse or conservatory, "How is it I can never manage to flower an Amaryallis? They are such beautiful things when in flower, and I try all I know to get them to bloom, but I can never succeed. In doing so, pray what is the reason? I always water them regularly with the other plants, but they don't seem to grow even." "Just so." And as I am sure there are many readers of the Magazine who could say the same of their Amaryallis, I will endeavour to set them all right in respect of growing them and blooming them as well. As my remarks on their cultivation are

founded on practical experience, all may safely go and do as I advise, and not err. It is only within the last two years that my attention has been drawn to this beautiful class of plants, and I felt very certain that something more might be done with them to bring out their beauty than had hitherto been done by possessors of them. So I got a small collection together, and tried my hand at them; and the result has been most successful, even far beyond my expectations. I first began with a few bulbs that were found neglected in various places, because their owners could do nothing with them; and before I took them in hand, I question much if they had been repotted for some years; and yet, in the face of that, they were expected to grow, and even bloom! But, however, I got them together in the beginning of February, and turned them out of the pots they were in, and shook away all the old soil, and mixed up in equal parts hazel loam, turfy peat, leaf mould, and sand. I then added a small quantity of thoroughly rotten manure, and well mixed the whole together, but leaving it quite rough and lumpy—in fact, the peat and loam were in lumps about the size of walnuts. I then got some clean pots; and, I will here add, it does not matter in the least how old the pots are, so long as they are sound and quite clean, and the crocks for drainage equally clean. It is surprising how much better a plant thrives in a clean pot than it does in a dirty one. After placing the drainage in the pot, and putting a thin layer of moss on them to keep them from being choked up, I placed over it next some of the roughest of the soil, and filled up the pot to within a few inches of the top. I then placed a bulb in the centre, and pressed it down moderately firm in the soil, and filled up the pot so as to leave the soil about a half inch below the rim, and the job was done. I would advise all who follow my practice to be sure, before potting the bulb, to remove all decayed leaves from the crown, and all dried bark or skin from the bulb itself; for if this is not attended to, it will be sure to rot when you begin to apply water, and injury to the bulb will be the result. Now I think that is all I need say about the potting part of the business, and I have been rather plain in giving the details, for much depends on trifling things being attended to, as many little things put together make up the grand whole. The next operation is where to start them in growth. But one thing is certain, they must have some heat to begin with. They do not care about bottom heat much, as the leaves do not come so fine with it. Ainery that is just started is a capital place for them; or, wanting that, let them have the coolest place in a stove, or an intermediate house will do, but not an ordinary greenhouse. No; by no means at first will a quite cool place do, although they will come to that after. Well, after placing them in their quarters, moderately water them, and give them a sprinkle every morning, but by no means sodden the soil. As they increase in growth, then increase the water as well, and you will soon find that they will push up flower-stems, and plenty of leaves. Talking about leaves, or, more strictly speaking, foliage, reminds me that I tried an experiment on one or two pots with liquid manure, just to see if I could increase the size of leaf and flower, and there was no mistake but that it agreed with them: for instance, on one named *Cœur de Léon* (there were two bulbs in a large pot) the result was a flower-stalk (one could call it nothing else) 26 inches in height, and 5½ inches around at the bottom! There were four flowers on each stalk, and the least of them was 7 inches across! And when the first was done, up came another stalk which also had four flowers on, of course not so high, but the flowers themselves were equally large. Then the foliage! It was like that of a leek, and about 2 feet long and 1½ inches across. And this I lay entirely to the liquid manure, because the bulbs that had none were by no means so fine either in flower or foliage. When they begin to show flower they may be then removed to a conservatory or greenhouse, and if kept in the shade they will last in beauty for near a month, or even longer. After they have done blooming, they should be removed back to their warm quarters again, to ripen and mature themselves. The flower-stalks will now gradually die off, and in time the foliage also; and when this takes place, gradually withhold water, so as to properly ripen them. But mind, even at their season of rest, *do not withhold water altogether from them*, for this is wrong; but just give them a little to keep the soil from cracking and quite drying up. They may now remain until you start them again in February, when shake them out and pot afresh, as before recommended; and by so doing, and following all directions as here set down, I am sure we shall never hear more of *Amaryllis* not flowering, and we ought not to hear of their doing bad in any way.

Speaking about *Amaryllis* reminds me of a little incident that took place here last summer, at the time that their allies the *Lilies* and *Vallota purpurea* were in bloom; in fact, I had a nice group of them, with a few *Amaryllis* mixed with them, all nicely in bloom and arranged together, and sweet and gay they looked too. Amongst their many admirers was a lady who is passionately fond of flowers, and the lily tribe in particular, as the sequel will prove. She was having a look around the nursery, and had it all to herself

to go where she pleased, as she was no stranger here; and by and by she came across this said batch of lilies and other bulbs, and after taking her own time in admiring them and enjoying their perfume she came down the greenhouse where I was employed making cuttings, and said, "Oh, Mr. Burley, I have had such a treat amongst your lilies! they are so sweet! I have had such a smell at them!" "Have you, ma'am?" says I; "that's right:" and as I said this I lifted my head up, or rather my eyes, when lo! such a sight! She had been smelling the lilies indeed, and the farina being ripe on the blooms, it had got all over and around her mouth and nose; in fact, the effect produced by the different tints of the farina on her face, and especially on her upper lip and the tip of her nose, was grotesque to see, and more especially as she smiled to tell me how she had enjoyed the treat, for the grimace produced by the moving colours had anything but the pleasant look she intended to have given me. "Why, madam," says I, when I could speak respectfully without at all smiling, "you have indeed been smelling the flowers, and they in turn have left the marks of it on your face." "Why," says she, "what do you mean?" as she took a white handkerchief from her pocket, and began to wipe her face and mouth, which operation, by the way, only made matters worse. "Why simply," I said, "the farina of the flowers has got about your face; but we have a little water here, which will soon set that right; but first look in this piece of looking-glass." She did so, and exclaimed immediately, "Oh what a fright! how odd I look!" and then she immediately began to laugh at the oddity of the affair. Well, the upshot was, the same handkerchief and some water soon set all right again, and it all passed off as a pleasant joke. So I must warn the fair readers of this article not to fall in a similar catastrophe when they are enjoying the perfume of their *lilies*, but to enjoy their delightful fragrance at a moderate distance.

JOHN BURLEY, F.R.H.S., &c., &c.

Albert Nursery, Pembridge Place, Bayswater, W.

Calendar.

WORK FOR WEEK COMMENCING MAY 25.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—The ground will be now for the most part covered, and everything in full growth. The hoe must never be idle; weeds grow faster than the crops, and exhaust the soil rapidly, and if allowed to seed make the mischief worse. Next to keeping down weeds, the most important operation is that of watering. Plants lately put out should not be drenched to excess, or the chill will check them more than a drought would, and it is better to trust to moderate watering and shade combined than to keep the soil soddened about plants that have barely taken root. Cucumbers, gourds, tomatoes, and capsicums may be put out; the soil should be rich, and for tomatoes a sunny aspect must be chosen. Sow beet, early horn carrots, scarlet runners and French beans, turnips, lettuces, radishes, cabbages, spinach, endive, cauliflower, and peas and beans. All salad plants should have a shady position, or they may run to seed. In sowing peas and beans it is best to depend on the earliest sorts at this time of year, as they are soon off the ground, but Knight's Marrow and Ne Plus Ultra are good peas to sow now for late supply.

CROPPING.—Sow succession beans, marrow peas, lettuce, Portugal cabbage, cauliflowers, Walcheren broccoli, Stone turnip, and turnip radishes.

CELERY to be got into trenches as fast as the ground can be made ready by the removal of other crops. Take up each with a ball, and do not injure a single leaf. Hoe over those that are established in trenches, to break the surface that has been hardened by watering.

HOEING AND WATERING.—Hoeing is one of the much-neglected operations of which few have considered the value, and to keep down weeds is generally the sole object of using the hoe. Certainly that is a good object, and if these observations quicken the vigilance of gardeners who are a wee' hit careless upon the growth of groundsel, couch, and bind-weed, and other rampant weeds among their crops, it will serve one good purpose. But it must have frequently come under the notice of practical men that a piece of cabbage or cauliflower frequently hoed between, even to the extent of working the instrument very near their roots, always grow to finer proportions than similar breadths left to take care of themselves, with the ground trodden between to the hardness of a Babylonian brick, "to keep the moisture in and the heat out." In such a case it is made evident that there is a virtue in the hoe beyond the killing of weeds that rob away the nourishment required by the crop; and if the problem of their well-doing is to be solved by observation, it must be at daybreak, when every leaf is loaded with dew. Then it will be seen that ground recently hoed or pointed over with a small fork is uniformly moist, while hard ground adjoining the same plot is almost as dry as during the heat of a sunny day. The solution is simple enough. The rough open surface absorbs a vast amount of dew, not simply because it is broken, but because it presents a greater extent of radiating surfaces, for the deposition of dew depends on the radiation of heat at the immediate surface, and the subsoil need not and will not be colder than the subsoil of hard ground, although it has a greater power of surface radiation. In fact, ground frequently hoed becomes warmer from its more ready absorption and conduction downwards of solar heat, so that the roots of the plants are kept warmer and moister in broken ground than in close hard ground, and therefore the vigorous growth of vegetation is promoted. M. Duchartre has made systematic inquiries on the deposition and effect of dew upon plants, and his conclusions are reported in the "Annales des Sciences Naturelles." In the conclusions there is nothing new. We have ourselves frequently indicated to gardeners that the chief benefit of dew to plants arose through its absorption by the soil for the nourishment of their roots.

M. Duchartre's experiments show that if the dew is allowed to settle on the leaves of plants, and not on the soil in which their roots are, they gain

nothing in weight, whereas, when the dew is allowed to condense on the soil, they gain considerably. A plant weighing 966.50 grammes was so placed that the soil in the pot had the full influence of the dew, and it had gained in weight, when the dew was removed from the leaves, 13 grammes. Another weighing 1034.25 grammes, gained 6.90 grammes. In other experiments, where the soil in the pots was hermetically sealed, there was not only no gain of weight by the dew, but a positive loss, which goes very far to prove that plants do not absorb much moisture by their leaf surfaces, and may perhaps give a new turn to our ideas on syringing. But let that pass, we will not throw away the syringe yet awhile. Plants with hard waxy leaves, such as *Veronica Lindleyana*, certainly do not absorb much, but they need to be kept clean; and plants with porous leaves, like the vine, do absorb largely, and may be kept alive for some time with the roots dried up, if the leaves are frequently wetted. But the hoeing is the matter we wish our readers to think about and act upon. The hoe is an irrigator of as much value to the English gardener as the shadoof is to the wretched cultivator of millet on the banks of the Zab or Tigris; and where people are wasting their strength in conveying hogsheads of water which are often more harm than good, the labour might in most cases be saved, the ground kept clean at the same time, and the plants encouraged to push their roots about in search for nourishment by the use of the hoe, and the hoe alone. Take notice of a rhubarb leaf; the mid-rib forms a depressed groove, and the leaf slopes up on each side of it, somewhat in the fashion of the two sides of a wooden water-shoot. The upper surface of the leaf-stalk is channelled too, and all night long the leaf distils dew from the atmosphere, the water trickles to the midrib, and thence finds its way by the channel of the stalk direct to the heart of the plant, for the benefit of its roots and rising leaves. This is the way nature makes almost every plant its own irrigator; we must co-operate with nature, and by the use of the hoe assist the soil also to drink freely of the dew of heaven, that we may enjoy thereby the fatness of the earth.

Flower Garden.

FLOWER GARDEN.—Newly-made lawns require a little special care at this season. If the grass is thin it must not be mown and swept in the usual way, for the roots of young grass suffer from the effects of a hot sun when there is not a close bottom to preserve moisture. It is a good plan to mow early, and leave the mowings till the evening, then sweep and clear up, and the grass will have twenty-four hours from the morning before the sun comes on it again, or, reckoning from the day before the mowing, thirty-six hours, which will materially assist in promoting a thickening of the bottom. Where walks look dingy, a turning with a fork and a good rolling is often as effectual a reviver as a supply of new gravel; but if the old gravel is of trifling depth or a had colour, a new coating will complete the beauty of the garden, and give it a necessary finish. Carnations, picotees, and pinks may now be propagated by pipings on the north side of a fence, or in pots half filled with sandy loam. The old plan of striking them in heat and in exciting composts is quite exploded as a fallacy. Ranunculuses will want water frequently; they cannot endure drought. Pansies strike readily from short side-shoots; the old hollow stems will strike also, but never make good plants; the new growth is that to be depended on. Dabbies not staked should be attended to forthwith; indeed, the stakes should be put in at the time of planting, so as to avoid damage to the roots when they have begun to grow. Perennials should be sown for next season's blooming, so as to get strong plants. Sow thin in nursery beds, and prick out the plants in rows as soon as they make rough leaves. If left crowded together they grow spindled, and never make strong plants.

GARDEN FLOWERS.—*Viola calcarata*, *montana*, and *cornuta*, *Bahia lanata*, *Salvia rugosa*, *Achillea montana*, *eupatorium*, *ptarmica*, *tomentosa*, *millefolia rosea*; *Silene maritima*, *Geranium endresii*, *sanguineum*; *Coronilla squamata*, *Spirea filipendula*, *Dictamnus fraxinella*, *Oenonis rotundifolia*, *Crucianella stylosa*, *Lotus corniculatus*, *Prunella Pennsylvanica*, *Verhascum phœnicum*, *Polygonum viviparum*, *Symphitum caucasicum*, *Lysimachia thursiflora*, *Lychnis viscaria splendens*, *Stenactis speciosa*, *Genista sagittalis*, *Armeria cephalotes*, *Vittadina lobata*, *Dianthus atrorubens*, *Lychnis Haageana*, *Dianthus cæsius*.

ROSES need abundant supplies of water now, and green-fly must be kept down, or the bloom will be impoverished. As the hurry of the hedging-out is now over, a little time may be found to look over briars intended for budding soon, to cut away weak ill-placed shoots, and shorten in the strong rambling shoots on which buds are to be entered. Generally the knife is used amongst the stocks at the time of budding, which gives them a check, and retards the taking of the buds. If cut in now as may be needful, both to strengthen the shoots to be worked, and make room between rows for the operation, they will break before budding time, and the sap will flow freely when it is wanted.

AMERICANS newly planted must have abundance of water overhead, as well as at the root. Remove by carefully snapping out with finger and thumb the dead blooms of rhododendrons and azaleas, to prevent seeding.

ATRICULAS will want occasional fumigating; keep them in a cool place, on a hard bottom, and pour water amongst them on the ground surface to cause a moist air. An old light may be rested on pots over them during storms; otherwise let them have the benefit of all showers.

ASTERS may now be turned out in the places where they are to bloom; make the ground rich, and choose showery weather. If the place is infested with snails, plant a few small lettuces behind the back row, which may be pulled up as soon as the asters are well rooted. Those to flower in pots to have a good shift and cold frame.

ANNUALS of quick growth, sown now, will bloom late for succession. *Nemophilas* never make a better effect than from sowings in June, in moist, shady places. Asters and balsams to be planted out during moist, dull weather.

CINERARIAS may now be earthed-up, to promote the rooting of the suckers. Throw away all seedlings of inferior quality, and propagate only the best. They require a cool shady place while making suckers, which are to be removed as soon as rooted. Sow seed for next year, and pot off rooted cuttings.

CAMELLIAS may be got out in a shady place, on a bed of tiles or coal-ashes, and kept frequently watered. If kept in the house, there must be air on night and day.

DAHLIAS planted out to be staked before the roots extend. Plant out all that are in pots at once; they will do better in the ground now than with any more nursing. The shoots of dahlias may be bent down so as to render very short stakes sufficient.

HERBACEOUS PLANTS may now be propagated from cuttings as they go out of bloom. Alyssums, wallflowers, perennial iteris, &c., are easily

propagated, and the borders may be richly furnished with them by a little timely trouble.

PANSIES.—Take cuttings of the best, look over seedlings, and root out and destroy all inferior ones. Sow again for autumn bloom.

TULIPS.—Remove the shading, and let them have the benefit of rains and dews.

HOLLYHOCKS.—Stake at once, and tie in as soon as the stems are tall enough, and frequently look at the ties to see they do not cut their swelling stems. Heavy manuring in the first instance is preferable to watering with liquid manure, but in poor soils liquid manure may be used abundantly.

Fruit Garden and Orchard House.

FRUITS IN SEASON.—*Apples*: French Crab, K D; Golden Harvey, D; Norfolk Beefing, K; Sturmer Pippin, D.—*Pears*: none.—*Grapes*: same varieties as last month; also Muscat of Alexandria, Bowood Muscat, Canon Hall Muscat, and Black Damascus.—*Various*: So many kinds of fruit are now in season from the forcing houses, that it is scarcely needful to enumerate varieties. In addition to grapes, which are abundant, good supplies may be expected of peaches, nectarines, apricots, plums, cherries, figs, pine-apples, gooseberries, currants, raspberries, apples, pears, and melons.

FRUIT.—Search among raspberries every morning for snails, which take shelter on the stakes and among the side-shoots. If large fruit are required, thin the blooms at once, and give liquid manure. Stone-fruits look well this season, and no blight yet, but it may come suddenly, and must be prepared for. Disbud and nail in. Pot-trees to have plenty of water, and if weakly in their new growth, pretty strong doses of liquid manure at intervals of at least a week each. Pinch, regulate, and where fruit shows thick, thin it out.

APRICOTS to be thinned, young shoots nailed in, caterpillars destroyed, and water-engine used smartly, if any sign of fly, which rarely troubles them.

WALL TREES to be nailed in, and the shoots thinned as they grow, that there may be no crowding of unnecessary wood. Shoots that run away with undue vigour to be cut clean out to the base, unless in positions where much needed, in which case shorten them back.

Greenhouse and Conservatory.

GREENHOUSE.—To prolong the beauty of the plants in flower, put up a shading of tiffany or Haythorn's hexagon net; the latter will also be useful to exclude bees and wasps, for flowers on which bees have settled perish sooner than those they have no access to, owing to their disturbing the pollen, and causing a formation of seed-pods. A method of prolonging the bloom of flowers, and in the opinion of some increasing their beauty, is to get some dissolved gum arabic and a camel's-hair brush. The brush is dipped in, and the centre of every flower touched with the gum, where it forms a bright head, and prevents the distribution of the pollen. Of course the flowers should be touched soon after they open, or Nature may have accomplished her end before the preventive is brought into operation. It is important to keep the first blooms on specimen azaleas, pelargoniums, &c., in this way, so as to get the whole plant covered by the time the latter blossoms open. Pelargoniums done blooming should be cut in and allowed to break before repotting. They should be kept rather dry, so as to break slowly, and when potted into small pots, put into a cold frame, and kept close till they begin to make fresh root, when they must have plenty of light and air. Cinerarias done blooming may be propagated by side-shoots and suckers; if the plants are turned out on a border, and heaped round the collar with sandy loam, they will throw out suckers, which may afterwards be slipped off with a portion of root attached. The time is now arriving for clearing out the house, and give it any necessary clearing and repairs, and cold frames should be provided in good time to receive those plants that are not to be turned out of their pots for the summer.

GREENHOUSE PLANTS NOW IN BLOOM.—Pelargoniums, both of the exhibition and zonale classes, are now brilliant, and fully take the places lately occupied by azaleas and cinerarias. Among the plants that are especially interesting, but not so well known as a certain few showy subjects, the following are worth enumerating as likely to be in bloom now: *Gastrolobium obovatum*, *Anthyllis tragacanthoides*, *Banksia speciosa* and *ericifolia*; *Diosma tetragona*, *longifolia*, and *tenuissima*; *Hardenbergia comptoniana*, *Aphelaxis humilis*, *macrantha purpurea*; *Kennedyia prostrata*, *Hovea elliptica*, *Jacksonia grandiflora*, *Marrayata nigricans*, *Abelia floribunda*, *Adenandra fragrans*, *uniflora*, *amœna*; *Cæsia vittata*, *Clematis odorata*, *Beaufortia latifolia*, *Calothamnus olavata*.—*Ericas*: *Rollisonii*, *odorata*, *pumila*, *rubella*, *Savileana Shannoniana*, *Sprengellii*, *spuria*, *Thunbergii*, *togata*, *tomentosa*, *transluens*, *tricolor*, *canescens*, *cinerea* (hardy), *staminea* (hardy), *parmenteriana*, *lachnæfolia*, *halicababa*, *acuminata pallida*, *imperialis*, *cubeia major*, *aristata*, *Beaumontiana*, *Bergiana*, *comptoniana*, *densa*, *Dicksonia*, *lævis alba*.

PELARGONIUMS now require much attention. See that stakes and ties are in order to keep the plants in the required form as they come into bloom, and remember that the fewer ties the more credit is due to the cultivator. This is such an important matter that varieties with a sturdy habit should always be preferred, unless there are some very strong inducements to select weak growers. Judicious stopping, plenty of light and air, and a sound compost, are points of great importance towards growing plants that will not need scaffolding. Give shade as the plants show flower, and keep the whole stock as cool and airy as possible, avoiding damp and cold draughts.

PETUNIAS left over from the bedding, and double varieties struck in spring, will now want shifting, to make specimen plants for autumn bloom in the conservatory. The same with all other soft-wooded summer-flowering plants. A little timely care will now put value into every scrap that has a leaf and a root.

FUCHSIAS.—Keep well shaded, well watered, well ventilated, and with a cool, moist bottom. Plants from spring cuttings will be useful in five and six inch pots, to keep the houses gay in company with balsams and other summer flowers.

AZALEAS not yet done growing, keep moist and shaded, but beware not to push the growth too far, as unless they are well ripened and rested there will be few flower-buds formed. There is not much danger of that, however, just yet, except with those fixed early. Plants that are leggy are likely to throw out shoots along the stems if laid on their sides.

HELIOtropes make rapid growth on hot walls, and are very useful to fill up blanks. Petunias may be used in the same way, to run up to five or six feet. Rich soil and plenty of water are requisite if such a free growth is required.

GERANIUMS propagated now will flower in the autumn; sorts of which a large stock is required for next year should be cut at as soon as established in the reserve ground. In bedding out use a trowel, and close in neatly, as the plants will not thrive with hard cakes of soil about them. Where the soil is very rich, and geraniums are found to grow too rank for flowering freely, merely raising the beds to render them dry will do much to ensure a gay bloom. Road-sand from gravel roads is the best of all soil for Tom Thumbs and other ordinary scarlets. Geraniums in beds, avoid watering if possible, after the first dose to settle the earth about them. They will root deeper and do better in the end. Pot plants want plenty of water, and if leggy pinch out the tops and give a shift, and plenty of side-shoots and blooms will follow to the end of the season.

Stove and Orchid House.

STOVE.—Liberal waterings must now be given, and abundance of air, especially among hard-wooded plants. Pines, same treatment as last month. New Holland plants should be encouraged to grow, and liberal shifts given as required.

ORCHID HOUSE.—All orchids from the eastern parts of the world will now require abundance of water. Advantage may be taken of sun-heat to lessen the expenditure of fuel, but there must be some ventilation. Orchids on blocks and in baskets require to be well soaked occasionally, and for this work the new "Orchid Bath," manufactured by Warner and Sons, is a most useful apparatus. *Cymbidium eburneum* and *C. giganteum* will probably require repotting now, and in so doing strong plants may be increased by dividing the bulbs. They require plenty of pot room, good drainage, and fibry peat in lumps. Many of the *Vandas* are now in their full beauty, and must be kept cool to prolong the bloom. As soon as they have done blooming repot them. *Stanhopeas* pushing their flower-buds through their baskets now, are occasionally injured by contact with the material of which the baskets are made, and an occasional examination will be necessary to prevent this. These will grow in either the Indian or Mexican house if managed with care. They require shallow baskets, with plenty of openings, so that the flowers may find their way through, plenty of water while growing, and after the growth is completed a long period of rest, during which they should be kept only moderately moist. Prepare flowering plants for the conservatory by taking them first to a vinery, or any structure of a temperature intermediate between the orchid house and the conservatory. Temperature of Indian house 70° to 75° by night, and 75° to 85° by day. Mexican house 65° by 70° by night, 70° to 80° by day.

CLIMBERS in free growth look best when left a little, to themselves, so as to display

The negligence of nature wide and wild;

but some tying and training must be done, and the cultivator must have an eye that the rods intended for future flowering are not unduly shaded by disorderly growths. There is a happy medium between training climbers in a severely artificial manner, and leaving them to sprawl about and choke themselves, which medium course it should be the aim of the gardener to discover and encourage.

ORCHIDS THAT MAY BE IN BLOOM IN MAY AND JUNE.—*Acinetia Humboldtii*; *Arides crispum*, *crispum Lindleyanum*, *crispum pallidum*, *crispum Warneri*, *Fieldingii*, *Larpenæ*, *maculosum*, *maculosum Schraderi*, *M'Morlandii*, *nobile*, *odoratum*, *odoratum cornutum*, *roseum*, *Veitchii*, *virens*, *virens superbum*; *Angræcum caudatum*; *Anguloa Clowesii uniflora*, *virginalis*; *Arpophyllum cardinale*; *Barkeria melanocaulon*, *spectabilis*; *Bolbophyllum Henshallii*; *Brassia Lanceana*, *Lawrenceana*, *maculata major*, *verrucosa*, *verrucosa superba*, *Wrayæ*; *Broughtonia sanguinea*; *Calanthe furcata*, *Dominii*, *masuca*, *veratrifolia*; *Cattleya Aclandiae*, *amabilis*, *citrina*, *Edithiana*, *intermedia violacea*, *labiata picta*, *Lemoniana*, *M'Morlandii*, *Mossie*, *quadricolor*, *Schilleriana*, *superba*, *Wagneri*, *Walkeriana*; *Chysis Limminghii*; *Cælogyne Lowii*; *Coryanthes macrantha*, *maculata*; *Cycnoches barbatum*, *chlorochilum*, *venticosum*; *Cypripedium Lowii*; *Dendrobium calceolare*, *cretaceum*, *Devonianum*, *Falconerii*, *longicornum*, *majus*, *transparens*, *tortille*; *Dendrochilum filiforme*, *Epidendrum alatum major*, *cinnabarinum*, *crassifolium*, *verrucosum*, *maculatum grandiflorum*; *Galeandra Bauerii*; *Huntleya meleagris*; *Lælia Brysiana*, *elegans Dayii*, *elegans Warneri*, *flava*, *grandis*, *purpurata*, *Williamsii*; *Odontoglossum citrosimum*, *hastilabium*, *nævium*; *Oncidium ampliatum* *majus*, *hifolium*, *divaricatum*, *longipes*, *luridum guttatum*, *phymatochilum*, *pulchellum*, *pulvinatum*, *pulvinatum majus*; *Peristeria cerina*; *Phalænopsis grandiflora*, *amabilis*; *Saccolabium ampullaceum*, *curvifolium*, *guttatum*, *guttatum giganteum*, *præmorsum*, *retusum*, *Wightianum*; *Schomburgkia tibicinia*; *Sobralia macrantha splendens*; *Trichopilia coccinea*, *crispa*; *Vanda cristata*, *Rexburghii*, *terres*; *Warræa cyanea*, *tricolor*.

BEGONIAS planted out in open ground not to have a drop of water on their leaves, and to be handled with great care. Shelter from wind is greatly needed.

Forcing Pft.

FORCED FRUITS.—As the crops are gathered give liquid manure to swell up the spurs for next year's crop; syringe with force to clear the foliage. Crops ripening to have less water, less syringe, more air, and full sunshine.

VINES to be frequently syringed, and every appearance of vermin to be dealt with promptly. Train in as soon as the shoots can be handled, that there may be no after-twisting and injuring. A dry air and dry border will promote the spread of red-spider, but moisture is death to this pest. Give Muscats plenty of heat.

THE FERTILITY OF NATAL.

The *Natal Mercury* publishes an interesting article on the prospects of Natal agriculture compiled from a report of the Maritzburgh Agricultural Society. It says, "A high standard of fertility has not been assigned to the soil of Natal, but there are tracts of exceptional fertility, equal to the rich prairies of western America, and yet not cursed by marsh or malaria. Note in proof of this opinion the enormous size to which the beet has been grown, specimens of from 80 lbs. to 100 lbs, being common, and in one case

the enormous size of 200 lbs, having been attained. Soil that can do this must be good—good enough the committee believe under proper conditions to grow wheat. They tell us they hope in a few years to see the northern districts not only the granary of Natal, but the source of a large wealth-creating export. This is an admission that naught but the conclusive experience of practical men on the committee can have caused or justified. We confess that the growth of wheat in the colony has not latterly been viewed by us as a certain resource, and we are but too glad to be set right. If Natal can grow her own wheat, an import of twenty or thirty thousand pounds' value per annum is saved. As an export we don't anticipate great things from wheat culture until railways are established. Australia and Chili, with their superior facilities of transport, will compete with us at too great an advantage for some time to come.

"The midlands are the more proper sphere of this society, and it is here that they are most sanguine. 'Varying as it does from misty heights to the almost tropical heat of the river bottoms, with its hill-sides covered with forest, and its valleys sprinkled with thorny mimosa, so various are its capabilities that it is impossible as yet to name the article which will become its staple.' At present, oats, maize, wheat, potatoes, and barley are chiefly grown, and cattle, horses, sheep, and pigs are reared. In 1865, 20,851 lbs. of butter, and 46,990 lbs. of bacon were produced, indicating the prevalence of European farming in the principal county. The committee, however, contemplate a much wider range of production. Coffee and tobacco, they think, may be grown largely to pay. The successful cultivation of the former in the inland districts will be entirely governed by the effects of frost. In Ceylon, it is said that many plantations thrive in high lands where a low temperature prevails; but the comparison between a country so strictly inter-tropical, and one that is decidedly extra-tropical, although near the coast, exceptionally warmed by special influences, can hardly be made with reason. However, it is known that coffee will grow near Maritzburg, and we have seen beans borne by a shrub growing on the city lands; but this question we must still regard as an unsettled problem. Coffee-shrubs may grow and may flower, and may even bear berries, with every luxuriant appearance, but it remains to be seen whether these berries will contain beans which, as to size and number, shall pay the grower. The committee calls attention to the kidney-bean as a desirable product. This plant grows with singular ease and rapidity all over the colony, and 'flourishes well in the lightest soils, and can be harvested in the dry season.' Such useful qualifications commend their possessor to notice. We observe that beans by the last quotation fetch an average price of 40s. per 484 lbs. in the home markets."

CATALOGUES.

JAMES VEITCH AND SONS, ROYAL EXOTIC NURSERY, KING'S ROAD, CHELSEA.—*Catalogue of New and Beautiful Plants*: This contains sixteen figures of new plants, most of them rendered with spirit and fidelity; in fact, in many instances the mere black and white of a spirited woodcut produces an effect scarcely inferior to the richest colouring. This is particularly the case in the figures of *Acalypha tricolor*, *Coleus Veitchii*, and *Gymnostachys Pearcei*. On the other hand, the representations of *Davallia alpina* and *Retinospora phænosa* are less happy; the lines are too hard and black. All things considered, these cuts are remarkable examples of what may be accomplished without colour, and the catalogue has an interest far above and beyond what ordinarily belongs to a trade circular.—*List of Select Soft-wooded and Bedding Plants, &c.*: A good list of plants now in demand, and of hardy herbaceous plants, and plants adapted for spring decoration.—*Plant Catalogue*: A complete summary of Messrs. Veitch's stock of stove, greenhouse, and hardy plants. It is, of course, rich in orchids, ferns, camellias, azaleas, and ericas, but there are also plenty of miscellanies. It contains for a frontispiece a figure of *Maranta Veitchii*. It is not often, in these days of elaborate catalogues, that we meet with the equals of these, either in beauty of getting up, intrinsic merit in respect of the subjects announced, or richness of illustration.

E. ABRAHAM, FORT PROSPECT NURSERIES, LIMERICK.—*Catalogue of Bedding Plants and Florists' Flowers*. Contains all the new dahlias and verbenas, and a good assortment of bedding plants of all kinds.

Correspondence.

PLAGUE OF NETTLES.—Will you direct me as to the best method of destroying the common nettle, in a situation where they are too numerous to eradicate singly, and where a large tool could not be used without doing mischief? My churchyard is so infested with nettles as to predominate over the graves and among the tombstones, and all around the church. Can you recommend me any chemical preparation, like sulphuric acid, which effectually destroys the plantain? If there is any tool that could conveniently be used in such a situation as I describe, I should be thankful to know of it. I shall feel obliged if you would give me your opinion and advice at your earliest opportunity, as I shall do nothing until I have it.

T. T., near Gloucester.

[In a case where it is impossible to grub up nettles, we should imagine the surest way of destroying them would be to cut them down to the ground on a hot day, and then strew over them a thick coating of common salt. This is a cheap remedy, and it would favour the growth of grass after the nettles were destroyed.]

Replies to Queries.

Mushroom Beds.—J. S.—There are many ways of growing mushrooms; some of the most careless ways are sometimes very successful, some of the most careful ways are sometimes failures. In the end the careful man will be the winner; and therefore, though the best ways fail sometimes, we recommend the following, which we consider the best:—Collect short manure from the stable daily, and lay it in a heap in a dry shed. So long as it rises to only a gentle heat leave it alone, and keep adding to it; but if there is any tendency to a strong heat, spread it out; leave it spread a day or two, and make it up again in smaller heaps. If it gets thoroughly hot, it will be in great part spoiled. When you have enough for the bed, mix with it a fourth part of good turfy loam; if the loam is stiff, use only a sixth part to the whole bulk. Lay it all up in a heap to ferment, and

when the heat rises to 80° or 90°, take it to the mushroom house, and make up the bed 18 to 24 inches deep. It will soon heat again, but not fiercely. When the temperature of the bed is declining from its first heating, and is at about 90° (80° to 100° will do as well), bore holes with a rammer about a foot apart, and put into each a piece of spawn the size of a walnut. Fill up the holes with some of the same stuff the bed is made of, then spread two or three inches of good strong loam all over the bed, and at once beat the whole firm. It is one of the most important of all the points in mushroom growing to make the bed as firm as a rock at the right moment—that is, when the heat is going down from the first rush, and is not more than 100°. Spread over the bed some clean dry straw, not hay, for that is apt to go mouldy; and thereafter keep the bed moderately moist, but never wet, and as far as possible let the atmosphere be close, damp, and averaging 55° to 70°. Generally speaking, water never need be given until after the first gathering of mushrooms has been made; but this will depend on the degree of moisture of the stuff when the bed is made: the experienced cultivator will take care to have it moist enough in the first instance to last five weeks, and will then expect to find the bed smothered with young mushrooms. In gathering, take them clean out of the soil; the practice of leaving the root in, with a view to disseminate fresh spawn, is had, for it attracts several kinds of flies, and these soon fill the bed with maggots, and it encourages snails and woodlice, which are as fond of mushrooms as we are.

Vines for Long-rod system.—T. H. D.—You may plant two or any number of vines in a house for the long-rod system, which requires the least amount of room. It is not by any means advisable to follow this system under glass, because of its uncertainty. You cannot make sure of good canes to take the place of the old ones that are to be cut out, and must occasionally fruit a cane a second time. Moreover, the system is somewhat exhaustive; so that vines thus treated are not likely to last so long as those that are allowed to extend somewhat from year to year. In ordinary cases it is not advisable to practise the long-rod system under glass, though there may be exceptional cases where it would be suitable.

Wireworm.—W. T. Gates.—Yours is a bad case, but not at all uncommon where a grass-field has been lately converted into a garden. Cultivation will eradicate the pest in time, as every time the land is dug the birds will make a feast of the vermin, and the use of lime and salt on the land when newly dug up will contribute to thin them. For the present, we can recommend a good plan to save the crops that are coming forward. Sow carrots in short rows in all the beds occupied with lettuces, onions, and other things that they usually destroy. As long as they can find their way to a feed of carrots, they will desert everything else, just as slugs and snails will quit everything else for lettuces. Sow the carrots now rather thick at intervals of about two yards across every four-foot bed, and as soon as they acquire the thickness of a quill begin to draw them where thickest, and you will catch many of the vermin. But you must allow a fair share of roots to remain, and you will have a crop of carrots in the end in spite of the worms. Next year sow onions and carrots, lettuces and carrots, &c., in alternate rows in the same beds; it is too late, we presume, to advise this course now.

Vines lately planted.—Vinery.—We do not think the small quantity of gas-lime mixed with the compost three months before the border was made has in any way contributed to check the growth of the vines. This has been a very bad season for newly planted vines, and we should not be troubled if we had planted, and had to wait till quite June to see them grow freely, unless we had command of bottom-heat to assist them. We have observed that many subjects that were exposed to severe frost last January have been very late in starting, and perhaps these vines were so exposed, and want extra time to recover. On this 22nd of May we have trees of common Sumach that stand in a cold draughty place that have not yet made a leaf, yet are alive, and slowly swelling their buds as if they meant to grow some day.

Books.—Constant Reader.—We really do not know of a book such as you want that we can recommend with confidence, except Lindley's "Theory of Horticulture," and that is expensive. There are many cheap hooks of the kind you inquire about, but they are bad.—T. Hardy.—Grindon's "British and Garden Botany," published by Routledge (price about 12s.), is a capital book for ready reference, and good popular histories of the principal British and garden plants. That it is not complete as a guide to garden botany is rather in its favour than otherwise as a work of general usefulness. The larger work you inquire about is Don's "Dichlamydeous Plants," in four volumes quarto. It is not to be obtained through the booksellers in the ordinary way, but may sometimes be met with second-hand. It is a work of great value, though in many respects out of date.—S. W. S.—You had best consult the "Rose Book," for it is impossible for us to make room now for papers on the whole routine of propagating, nor perhaps would it be desirable.—R. W. B.—"Recreative Science" was completed in three volumes. You can obtain them through any bookseller. The price is about 30s. or less.—C. B.—Get Moore's "Mannual of British Ferns," and put the Fleet-Street book behind the fire. Moore's volume will cost 5s. The cheaper hooks by Mr. Moore are neither nice nor original, but the "Mannual" is a masterpiece.

W. R., Northwick.—There does not appear to be any peculiar merit in your pansy.

J. M., Dover.—The best way will be to make the house in the form of a lean-to, with narrow path at the back, and a bed two feet deep over the flue. You can have any degree of humidity you like by wetting the floor, and keeping the bed reasonably moist.

E. L.—Impossible to name your plants. One a piece of shrivelled leaf two inches long, probably *Verstrum album*; the other may be an aloe, but it is a mere scrap, shrivelled up.

Gas-water and Gas-lime.—Subscriber, Canada West.—The ammoniacal liquor is chiefly useful to promote the growth of plants that are required for their leaves, such as spinach, lettuce, endive, &c. It is generally used as a liquid manure when the plants are growing vigorously, and the proportion of water to be added must be at least twenty times the bulk of the liquor of the average strength. But the liquor may be used undiluted to soak plots of ground after they are prepared for sowing and planting, one good soaking only being given, and then some little time must elapse before sowing or planting. In ground infested with wireworm or the grub of Daddy long-legs, it is a good preparation for carrots, onions, and indeed for any crop; but it is advisable always to apply the stuff some time before sowing or planting. Gas-lime is of comparatively small value; therefore but a small price should be paid for it, for the ammonia it contains is but trifling in amount. As lime it is of course useful, and makes an excellent top-dressing, if sown at the rate of twenty to thirty bushels per acre. The best

way to apply this is immediately after the crop is sown or planted, as it protects the young plants from insects, and will not harm any it falls upon unless used in excess.

Ivy on a Wall.—Sunderland.—No; it was never known that ivy on a wall caused dampness, unless the ivy hung out from the wall and caught the rain in some peculiar aspect, or under the drip of a leaking gutter. Ivy properly kept to a wall is preservative. There was an elaborate inquiry once into this question at the instance of some churchwardens, who wanted to remove the ivy from a church, and the churchwardens got a wholesome rap upon the knuckles. You will find the story in the first volume of the "Floral World." Churchwardens, as a rule (and district boards, &c., &c.), have a peculiar penchant for mutilating trees and shrubs. Some wise men of this sort have lately been chopping up fine trees on the road to Highgate, and have thereby spoiled one of the prettiest walks out of London. In this they make common cause with some of the jobbing gardeners about London, who think all trees should be cut down, and all herbaceous plants dug up.

Cupressus torulosa.—J. C. C.—The tree you inquire about is not a Thuja, but a Cupressus. It is the "King pine" of the "Nynee Tal," and the "weeping cypress" of travellers. The leaves are very small, closely imbricated, very glaucous, the whole of the growth pendent, the branchlets closely covered by imbricated scale-like leaves, arranged in four green rows resembling small green cord. It forms a fine pyramid tree, where it will live, but is, generally speaking, too tender for this climate. The specific name is supposed to be derived, says Gordon ("Pinetum," page 70), from the bark peeling off in long twisted stripes.

Bedders to follow Herbaceous Plants.—S. W. S.—It will not kill your tuft of Iberis, Alyssum, Polyanthus, and Arabis, to move them now, if you do it with care. We transplanted a lot of such things a fortnight ago, just as they began to decline in beauty, and they are now as fresh as Dan Martin when he had slept seven days on the mountain, and had a draught from the witch's hoiling kettle to put him in mettle for dancing a jig. The earth is now moist, and the atmosphere cold. Lift and transplant at once, taking care not to knock all the earth off their roots. Do the work quickly and neatly, and by next October your plants will be fit to transfer to the borders again.

Intermediate Stocks.—J. Kirkland, Albion Nursery, Stoke Newington.—The plants are in the form of neat dwarf bushes with 9 to 12 solid spikes of large deep red flowers, thoroughly double and every way handsome. If they are sent for an opinion, we have but to say they are excellent.

Polyanthuses.—R. Webb, Calcot Gardens, Reading.—Yours are the finest for border and shrubbery decoration we have seen, but no florists' flowers amongst them. When put in a vase they quickly freshened up, and were admired for their fine colours, and the great size of flowers and trusses, they are, in fact, gigantic. Amongst them we observed a breed of cowslips, remarkably robust with orange-red and vermilion coloured flowers, splendid subjects for spring display. We have a batch of common cowslips, which year by year are changing to this style. Some of the flowers this season were of the intensest orange-red, quite distinct from everything else in flower at the same time. You ought to sell tens of thousands of your giant polyanthuses, for very few people who love spring flowers have anything like them.

Clematises.—J. H. W. T.—*Clematis azurea grandiflora* will suit you admirably, and Jackson's new varieties ought to; they are not, in our opinion, at all deficient of good foliage, and the flowers are grand. Try also (if you can get them) *campaniflora*, *cylindrica*, and *integrifolia*.

Geraniums.—Beginner.—If you put your plants in the shade till August they will be drawn and pale in colour. Better to keep on stopping and shifting till the middle of July, and then let them go ahead. They will then flower finely. Keep them in a sunny house with plenty of air. Nip out the points now, and remove all flower-stems. A week afterwards shift them to the next size. Train out the growth to make nice round heads. Stop again at the end of June, and a week after stopping give another shift. In the middle of July stop again, and a week after shift. After that leave them alone, and by the middle of August they will be in bloom superbly. The best in the list you name are St. Fiacre, Excellent, Rosamond, Lucius, Wiltshire Lass, Duchess, Beauty, Culford Rose. You want a white, such as White Perfection or Snowball. You cannot keep back the Glorinias; let them flower.

ROSE CROP.—Mr. Blunt, the British Vice-Consul at Adrianople, in his report to the Foreign-office this year, gives an account of the rose fields of the vilayet of Adrianople, extending over 12,000 or 14,000 acres, and supplying by far the most important source of wealth in the district. This is the season for picking the roses—from the latter part of April to the early part of June; and at sunrise the plains look like a vast garden full of life and fragrance, with hundreds of Bulgarian boys and girls gathering the flowers into baskets and sacks, the air impregnated with the delicious scent, and the scene enlivened by songs, dancing, and music. It is estimated that the rose districts of Adrianople produced in the season of 1866 about 700,000 miscals of attar of roses (the miscal being 1½ drachms), the price averaging rather more than 3s. per miscal. If the weather is cool in spring, and there are copious falls of dew and occasional showers, the crops prosper, and an abundant yield of oil is secured. The season of 1866 was so favourable that eight okes of petals (less than 23lb.), and in some cases seven okes, yielded a miscal of oil. If the weather is very hot and dry it takes double that quantity of petals. The culture of the rose does not entail much trouble or expense. Land is cheap and moderately taxed. In a favourable season a donum (40 paces square) well cultivated will produce 1,000 okes of petals, or 100 miscals of oil, valued at 1,500 piastres; the expenses would be about 540 piastres—management of the land, 55; tithes, 150; picking, 75; extraction, 260—leaving a net profit of 960 piastres, or about £8 11s. An average crop generally gives about £5 per donum clear of all expenses. The oil is extracted from the petals by the ordinary process of distillation. The attar is bought up for foreign markets, to which it passes through Constantinople and Smyrna, where it is generally despatched to undergo the process of adulteration with sandal-wood and other oils. It is said that in London the Adrianople attar finds a readier sale when it is adulterated than when it is genuine.

* * * Subscribers requiring back Numbers or Parts of the GARDENER'S MAGAZINE to complete sets, are requested to order them through their bookseller, who can always procure them from the London publisher. At the same time, instructions should be given that in case some of the numbers required are out of print, as many as can be had should be sent, it being a rule with the book collectors, if they cannot obtain ALL the numbers wanted not to take any, saying they are "out of print."

The Gardener's Magazine.

SATURDAY, JUNE 1, 1867.

MAY FLOWERS are not by any means so scarce as might be supposed from a casual inspection of gardens that are furnished according to the dictates of fashion. In the process of developing the summer display by means of geraniums, verbenas, and the rest of the popular bedding plants, the May flowers have been well nigh extinguished locally; and throughout the month of May, when for the first time in this climate we can really enjoy the open air, the principal display made consists of empty beds where flowers are to be, if we will wait till July. The bedding system has secured for us during May an exhibition of box edgings enclosing compartments of bare mould, for of necessity the beds must all be cleared in time for their summer occupants, the planting of which must depend upon the state of the weather. Nevertheless, we repeat that May flowers are not by any means so scarce as might be supposed from a casual inspection of gardens that are furnished according to the dictates of fashion; and we shall follow the dictates of nature in looking for them where fashion has not yet become dominant. We may have seen lately several species of perennial *Iberis*, like sheets of snow, and quantities of *Alyssum saxatile*, brighter than gold, and several of the *Aubrietias* may still be flowering freely, and affording refreshing knolls of rosy lilac or purple, and the elegant *Dielytra spectabilis*, in places well sheltered, may yet be gay with emerald green leaves and lovely pink flowers. But all these belong more or less to April, and are generally past their best before May is out; and when the weather begins to be like summer, as it has been since Sunday last, we see only the dull remainders of such things, and have the same retrospective comfort in them as the summer bedders afford us in prospect. The four subjects named are doubtless the four most valuable of all known hardy plants of the herbaceous kind for the embellishment of the garden during the latter end of April and the early part of May, but when they are gone there is in most places an aching void, which is somewhat ameliorated by the fact that the bedders are ready to put out, and will be planted shortly. Now we trust we can find a few subjects worthy to carry on the colouring until summer subjects are quite presentable, and we will name *Iris pumila* as one of them. Persons who know the plant only as it occasionally appears as an isolated tuft in a neglected border can have no idea of the beautiful effect that may be produced by planting the several varieties of this pretty iris in continuous lines, or by their association systematically in beds. There are at least five varieties, the colours of which are respectively white, dark blue, bright blue, pale blue, and buff yellow. No peculiarities of soil or situation are required to ensure a free growth and abundant flowering of this pretty dwarf iris, and the varieties are all to be found in good trade collections of hardy plants. Another subject worth especial mention is the *Pyrethrum*, the varieties of which are now numerous and distinct enough to furnish materials for exhibitions of not less interest or attractiveness than many other special subjects that have long enjoyed popularity. Comparatively few amongst observant and enterprising gardeners are as yet fully acquainted with the merits of the *Pyrethrum*, but the best may all be seen now in full splendour in Mr. Salter's nursery at Hammersmith; and to see is to believe that the flower, in its present highly improved condition, is admirably adapted for purposes far more important than any to which it has been hitherto applied in gardens. It is just one of those well-doing subjects that we should like to see introduced into the parks and public gardens about London, for, like its near relative, the *Chrysanthemum*, it is a good town flower, and is sure to interest persons who have any taste for florists' flowers, besides being eminently showy in respect of colour long before any ordinary bedding plant has a single flower out—before, indeed, such things as geraniums are usually planted. Mr. Salter's catalogue enumerates about 150 varieties; from these a dozen or two may be easily selected for any special purpose, for great masses, in which case colour and habit of growth would be the most important features; or for an amateur's collection of subjects, enjoyable at a time when flowers are scarce, in which case the form of the flower would be a matter of the highest importance. The following have been selected

No. 109, NEW SERIES.—VOL. X:

lately as likely to give satisfaction in almost every case that can be imagined, but we are strongly inclined to the belief that all are good:—*White and Blush*: *Album plenum*, Annie Holborn, Boule de Neige, Bridesmaid, Candida plena, Madame Fourcade, Madame Thibaud, Princess Alexandra. *Rose and Red*: Ariadne, Boule Rose, Brilliant, Eximium, Floribunda plena, Herman Stenger, Irocyana, Marguerite d'Anjou, Michel Buckner, Nemesis, Pink Pet, Rev. J. Dix, Rose Perfection. *Crimson and Dark*: Fulgens plenissima, Lysius, Prince of Wales, Purple Prince, Purpurea plena, Wilhelm Kramper. Our list of flowers is by no means exhausted, but it may be well, perhaps, to give the few subjects to which attention has now been directed the best possible chance of meeting with attention by withholding the names of any others for the present.

THE MOUTAN OR TREE PÆONY was the subject of some interesting and highly practical observations by our esteemed contributor Mr. Prosper, in the autumn of last year (*vide* GARDENER'S MAGAZINE, Sept. 22, 1866), and some interesting correspondence ensued thereupon. In the contribution of our friend it was confidently asserted that the failures that had attended the many attempts to cultivate this magnificent plant in the open air in this country were to be attributed to the common but mistaken practice of selecting for it the warmest exposure possible, and giving preference to a low position rather than one elevated and exposed to all the winds of heaven. Many of our readers will remember the statement made by Mr. Bateman, at one of the scientific meetings of the Royal Horticultural Society (*vide* GARDENER'S MAGAZINE, July 11, 1863), to the effect that the "most sheltered spot in the garden at Biddulph Grange" was selected for a plantation of Moutans, but "after ten years' cultivation only one season could he pointed to in which they flowered at all satisfactorily." Mr. Bateman concluded that the climate of North Staffordshire was unsuitable for the out-door cultivation of the plant, and thenceforth the attempt was made to cultivate them in the border of an orchard house, "where they have flourished marvellously." On Friday week last (May 24th) we saw, in the beautiful garden of Richard Headly, Esq., of Stapleford, near Cambridge, many fine Moutans covered with noble flowers, and were assured by the veteran florist that in the comparatively bleak climate of Cambridge they flower every year profusely, and occasion no more trouble than the hardiest shrubs and border flowers in cultivation. Some of the plants measure four or five feet through, and produce hundreds of flowers of the most gorgeous character. There has never been a difficulty as to their growth and flowering, and Mr. Headly, with his accustomed enterprise and accomplished skill, has sought to improve their character and increase the varieties by cross breeding, and has succeeded, just as he succeeds with everything of the kind he takes in hand. There is one fine bush, the result of a successful cross, which at the present time presents a beautiful and novel appearance, the leaves being all margined with a reddish buff-coloured variegation—a display of colour which renders flowers unnecessary, or rather the variegation is so bright that the removal of the flowers might be as advantageous as in the case of many of the variegated-leaved pelargoniums. So much for Moutans at Cambridge, seen on the day after a terrible May frost, which made potato-haulm in the same district as black as ink, and quite killed kidney-beans and many other subjects just pushing through the soil. The tree pæonies were unhurt, and in wealth of leaves and flowers were without parallel.

The Moutans at the Crystal Palace were referred to in Mr. Prosper's paper. On the occasion of the recent flower show there (May 25th) we saw them covered with flowers, not a leaf injured either by the gales or frost that have marred the present spring, though they are exposed to winds that are literally killing the araucarias only a few yards distant from them. As compared with Mr. Headly's plants, the Crystal Palace Moutans are poor; but if we can forget the Stapleford beauties, we may pronounce those at Sydenham to be rich and glorious, worthy companions of the rhododendron, the kalmias, and the hardy azaleas, all of which flower at the same season, and are the chief glory of our gardens at this time of year. A sound loam, well-drained, and full exposure seem to be conditions far more suitable to the Moutan than over-rich or damp positions, or any kind of shelter. Their requirements, therefore, are all in favour of their more general cultivation in English gardens, and they are amongst the grandest of all the hardy plants at present known to cultivation.

THE ANNIVERSARY DINNER OF THE GARDENERS' ROYAL BENEVOLENT INSTITUTION will take place on the 27th of this month, under the presidency of Sir Robert Peel, Bart.

DELIRIUM TREMENS cannot be restricted to human subjects if what Professor Lecocq says of plant tremors be true. He has observed in the leaves of *Caladium esculentum* tremors continued for fifteen to twenty hours at a stretch, and by attaching bells to the plants and using a stop-watch, he has ascertained that the tremors average one hundred per minute. On one occasion the plant shook so violently that the hand of a man [strong man we presume] was not sufficient to steady it. A *Strelitzia*, a *Philodendron*, and a *Begonia* placed near the jumping *Caladium* were infected, and began to tremble with it. While engaged in shaking the leaves the *Caladium* emitted jets of water! Exhibitions of natural extravagancies always pay well, and here is a hint for showmen, who, when spotted boys and six-legged calves no longer attract, may find a travelling conservatory containing plants that throb, jump, tremble, ring bells, and spout water, a very profitable speculation. It is a pity the leaves spouted water only; if they could but spout a little eloquent persuasion, we might be induced to believe what, for the present, we look upon as the invention of a brain in which originate the tremors attributed to plants.

A FLOWER OF MARECHAL NIEL ROSE was lately exhibited at Nottingham market; it measured five inches in diameter, and was of a rich golden colour. The exhibitor was Mr. J. Gibbons, jun., of Bramcote.

THE ROYAL BOTANIC SOCIETY'S FIRST GREAT SHOW on Wednesday last was a brilliant success, and an appropriate inauguration of the present season. The weather was not all that could be desired.

AT THE MEETING OF THE ROYAL GEOGRAPHICAL SOCIETY on Monday last, it was announced that the expedition in search of Dr. Livingstone will leave England on Whit Sunday, the 9th of this month.

ROYAL PARKS AND PLEASURE GROUNDS.—There are fourteen Royal parks and pleasure grounds in or about London, the parks being those of Battersea, Bushy, Greenwich, Hampton Court, Kennington, Kensington, Regent's, Richmond, St. James's, Green, Hyde, and Victoria, and the pleasure grounds of Hampton Court and Kew. The grounds of the Hospital and Military Asylum at Chelsea, with Holyrood Park and Longford River, are also included under the above heading, the total estimate of charges connected with which amounts, for the financial year 1867-8, to £125,326. Of this sum £5,095 are paid to the Ranger's departments of Greenwich, Richmond, St. James's, Green, and Hyde Parks, the grounds of the Hospital and Military Asylum at Chelsea costing £1,704. Under particulars of extraordinary expenditure appear sums of £1,075 for continuation of the river embankment and other works in and around Battersea Park; of £5,392 for lighting Primrose Hill, laying out ground opposite the Coliseum, and rebuilding a suspension-bridge over the Regent's Canal; of £16,347 towards the erection of new iron railings and foot-gates round Hyde Park (which item alone amounts to £10,050), setting back the carriage and footways at Stanhope Gate, putting down gas-mains and erecting lamp-posts on four principal roads in Hyde Park, and alterations of the Lodge at Stanhope Gate. The estimate is limited to such expenses in the several Royal parks and gardens as are requisite to maintain them for public use, and the income derived from them (which amounted last year to £4,807) is paid into the Consolidated Fund.

ROYAL BOTANIC SOCIETY.

FIRST GREAT SHOW, WEDNESDAY, MAY 29.

This was considered the second best show ever held in the gardens; it was certainly as rich in interest as in beauty, and from any part of the tent the spectacle was at once complete and gorgeous. The groups of azaleas, roses, orchids, mixed stove and greenhouse plants, the long bank of pelargoniums, the isolated banks of herbaceous calceolarias and miscellanies, were judiciously divided by masses of green ferns, palms, and other relieving agents; and the general effect fully justified the exclamations of surprise and wonder that were uttered again and again as the visitors entered the tent. There is no other floral fête proper to the London season that can compare with one at the Royal Botanic Gardens, for the ground, the tent, the management, the grouping of the subjects, are all perfect in their way. Unfortunately, the weather voted against success. From about one o'clock there was an occasional deluge, scarce a drop of which came through that well planned tent; but it ruined the promenading, and cast a gloom over the whole day's proceeding. For horticulturalists, and especially for those who were in the professional crowd in the forenoon, the treat was of the very best; there were many superb examples of skill in the treatment of old subjects, and many interesting and valuable novelties, not the least important of the last named being the *Tricolor-leaved Geraniums*. I shall report this show rather fully, in order to bring before our readers some lists of good things. Future shows of this season need not be so fully dealt with, as we do not seek for mere repetitions.

AZALEAS.—In the trade class for eight there was a nice point for the judges to choose between Mr. Turner's gigantic and glowing pyramids and Messrs. Glendinning's smaller plants but better flowers. Any one of Mr. Turner's plants would have made four of Glendinning's, and as plants they were superb in freshness and finish. Comparing the flowers of the two collections, there could be no doubt Messrs. Glendinning's were the best, and we may safely allow a few points on that account in their favour. But against these few points Mr. Turner must have many for the size, perfect training, and perfect uniformity of his plants; and Messrs. Glendinning and Sons must lose a few for bad training, for some of their plants were just the counterparts of the milkmaids' crinolines that *Punch* has caricatured so humorously and so happily; in fact, as a rule they had no shape, but the flowers were abundant, evenly mixed with leaves, and first-rate in quality. Now who shall be first, and who second? I say, first Mr. Turner, second Messrs. Glendinning, for we are judging plants; the judges say, Messrs. Glendinning first, Mr. Turner second; there is nothing more to add except the inevitable conclusion that the judges were wrong. In Messrs. Glendinning's lot were *Extranei*, *Iveryana*, *Eulalie Van Goert* (finely done, the flowers immense, and with leaves peeping through all over; the plant a perfect pyramid), *Perryana*, *Madame Meilhez*, *Variegata*, *Alba lutescens*, *Gera*. Second, Mr. Turner, with gigantic and uniform pyramids (the same, in fact, as were shown at the International last year, but the flowers reduced in size through over work), comprising *Gigantea*, *Conqueror* (quite right every way, full of fresh flowers), *Etoile de Gand*, *Gera*, *Coronata*,

Gledstanesi formosa (a grand white with occasional red stripes), *Perryana*, *Illustris nova*. In the class for six, first Mr. Turner, and this by an almost equally incomprehensible judgment as the last named decision. The plants were immense, but far from perfect as plants; some of them were thin on one side, though well faced up for grouping. Nevertheless, they were fine examples, immensely attractive; but if the judgment of the eight were right, these six ought to have been second, for Messrs. Lee's plants that were placed second were just on a par with Messrs. Glendinning's as to want of uniformity and finish and perfection of flowers. First, Mr. Turner, with a mixed lot in size and style, comprising a splendid *Petunæflora*, a huge *Juliana*, a neat Flower of the Day, a *Holfordii* (with large gaps on one side), a huge and beautiful *Sir Charles Napier*, and a very good *Iveryana*. Second, Messrs. Lee, with a pretty group, no two plants alike in size and shape; the varieties were *Iveryana*, *Marie Louise*, *Juliana*, *Duchesse Adelaide de Nassau* (a gaunt specimen, in great need of knife and bast), *Murryana*, and a union plant of *Gledstanesi* and *Variegata*. Third, Messrs. Lane and Son, with *Obelsoni*, *Magnificenti*, *Eulalie Van Goert*, *Sir Charles Napier*, and another. In the amateurs' class for eight, Mr. Carson, gardener to W. R. G. Farmer, Esq., Cheam, first, with *Barclayana*, *Criterion*, *Formosa*, *Murrayana*, *Holfordii*, *Exquisita*, *Apollo*, *Iveryana*. Second, Mr. G. Wheeler, gardener to Baron Goldsmid, Regent's Park, with *Duc de Nassau*, *Prince of Wales*, *Obelsoni*, *Magnificenti*, *Reine des Belges*, a glorious *Apollo*, a perfect *Albagrandiflora*, and a good Mrs. Fry. Another nice point here: Mr. Wheeler's plants are the most uniform and the richest in colour of the two, yet he gets a second. I give it up; the azalea judging on this occasion was such as no fellow can understand. Third, Mr. Penny, with beautiful examples of *Baron de Pret*, *Magnet* (a grand and perfectly finished pyramid), *Holfordii*, *Magnificenti*, *Extranei* (fine), *Iveryana*, a model *Duchesse Adelaide de Nassau*. Fourth, Mr. Wilkie, gardener at Oak Lodge, Kensington. Very nice groups of six each were shown by Mr. Peed, Mr. J. Wheeler, gardener to J. Phillpot, Stamford Hill, and Mr. Smith, gardener to A. Anderson, Esq., Norwood.

PELARGONIUMS.—These were displayed on the long bank at the upper end of the tent, where in former times the orchids were located. They made a marvellous display of colour. In the show section: First, Mr. Turner, with huge and finely-finished specimens of *Royal Albert*, *Pericles*, *Belle of the Ball* (a pretty salmon pink, with dark top), *Desdemona*, *Spotted Gem*, *Patroness*, *Lord Clyde*, *Lilacina*, *Fair Rosamond*. Second, Mr. Fraser, Lea Bridge Road, with *Leander*, *Desdemona*, *Etna*, *Empress Eugénie*, *Rose Celestial*, *Lilacina*, *Pizarro*, *Ariel*, *James Lodge*. In the amateur class: First, Mr. Nye, gardener to E. B. Foster, Esq., Clewer Manor, Windsor, with *Garibaldi*, *Patroness*, *Belle of the Ball*, *Etna*, *Rose Celestial*, *Fair Rosamond*, *Sir Colin Campbell*, *Madlle. Patti*, *Desdemona*; a fine lot, in the best style of training and everywhere in perfect finish. Second, Mr. Ward, gardener to F. G. Wilkins, Esq., Leyton, with *Beacon*, *Pericles*, *Rose Celestial*, *Empress Eugénie*, *Sir Colin Campbell*, *Desdemona*, *Madlle. Patti*, *Lilacina*, *Garibaldi*. Third, Mr. Wiggins, with *Alba formosa*, *Flambeau* (fiery, but scarcely a show variety), *Maid of Honour*, *Cynosure*, *Pericles*, *Regina formosa*, *Princess of Denmark*, *Royalty*, *Aimée*. Fourth, Mr. Weir, gardener to Mrs. Hodgson, Hampstead, with *Argo*, *Belle of the Ball* (lively flame carmine), *Etna*, *International*, *Queen of Beauties*, *Pericles*, *Attraction*, *Sir Colin Campbell*, *Virginia*. In the fancy section, first, for six in the trade class, Mr. John Fraser, with specimens that I venture to characterize as the best ever shown; they were as uniform as if they had all been cast in one mould of a shallow concave form, the plants having low convex heads of nearly the same size throughout, say five feet over, swelling enough to be far from flatness, yet showing every flower even to the edge; the varieties were *Clara Novello*, *Celestial*, *Maroon*, *Lucy*, *Roi des Fantaisies*, *Arabella Goddard*. Second, Mr. Turner, with grand examples of *Roi des Fantaisies*, a superb *Delicatum*, a one-sided *Lady Craven*, *Lucy*, a grand *Godfrey Turner*, *Ellen Beck*. In the amateur class, first, Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, with splendid specimens of *Bridesmaid*, *Queen of the Valley*, *Lady Craven*, *Miss in Her Teens* (showing too many ties), *Rosabelle* (superb), *Clara Novello*. Mr. Weir showed *Lady Craven*, *Mrs. Stewart Hodgson*, *Evening Star*, *Bridesmaid*, *Celestial*, *Delicatum*. Mr. James, of Isleworth, showed *Silver Mantle*, *Princess Helena*, *Cloth-of-Silver*, *Godfrey Turner*, *Mrs. Marnock* (in the style of *Godfrey Turner*, but lighter and brighter), *Mrs. Ford*.

(To be completed next week.)

CRYSTAL PALACE FLOWER SHOW, MAY 25TH.

The first show of the new season was one of the best ever held at the Crystal Palace, and was favoured by pleasant weather, a few degrees warmer than the temperature that prevailed during several days previously. But exhibitors had not much to say in favour of the weather, for the frost during the night and early morning had found its way into several of the vans, and the consequence was the complete destruction for all exhibition purposes of several fine plants. Some of the frosted plants drooped as if they had not tasted water for weeks past, others were curled and shrivelled as if operated on with curling irons by a hairdresser, and a few were blackened and nearly dead. Only in one instance, however, did this interfere with the general splendour of the exhibition, and that was a case which interested all. Not only was it a grand show, it was extensive also, occupying the whole length of the nave right and left of the great orchestra, extending in fact from the cool tank at the ethnological end to the screen which is now the rear wall at that end. The arrangement consisted of a central table and stages on either side, with walks up and down for the company. At the orchestra opening, and running back into the concert room transept, were special groups of plants of peculiar attractiveness, and at the corners in this conspicuous position were the great collections of Azaleas. We must again complain of one great fault in the method of the show, and that is the placing of the plants on ill-looking, dirty, dark green wooden stages. Green baize is no doubt costly, and is quickly destroyed by the placing of pots on it, but grass-mowings might be tried, and they could be obtained from the garden fresh, and in any quantity. Certainly there is a reform needed in respect of the staging of the plants, and we shall hope for something better yet than the ugly ground-work that has been adopted for several years past.

AZALEAS were important features of this show. The principal competitors in the trade class for eight were Messrs. Glendinning first, and Mr. C. Turner second. The award was no doubt simply and solely the conse-

quence of the frost, for Mr. Turner's plants both in respect of size and finish were many points in advance of Messrs. Glendinning's; but one of them, Conqueror, was completely conquered by frost on the journey, and all its leaves and flowers hung about it like rags. What it ought to have been was sufficiently set forth by the magnificent pyramid plants, vast in dimensions, faultless in training, and gorgeous in colour, that constituted the remainder of the group; *Purpurea* and *Petunæflora* especially were matchless in splendour. Messrs. Glendinning's plants were not so large nor so regularly trained, though as to bloom and freshness the best in the show, and most properly placed first under the circumstances. Very nice groups were shown by Messrs. Lee, of Hammersmith; and in the amateur classes by Mr. Penny, Mr. Carson, and Mr. G. Wheeler. In these collections were examples of *Triumphans*, *Chelsoni*, *Perryana*, *Extrani*, *Criterion*, *Iveryana*, *Petunæflora*, *Purpurea*, *Admiration*, *Madamo A. Verschaffelt*, *Murrayana*, *Fascination*, *Duchesse de Nassau*.

Roses constituted another most important feature, the banks of pot plants having a grand appearance, Messrs. Paul and Son and Mr. William Paul being each first in the classes in which they competed. In these groups were beautiful examples of *Alfred de Rougemont*, *Prince Camille de Rohan*, *Charles Lefebvre*, *François Lacharme*, *Madame Victor Verdier*, *Oliver Delhomme*, *Beauty of Waltham*, *John Hopper*, *Victor Verdier*, *Centifolia Rosea*, *Marguerite de St. Amand*, *Madame Souper*, *Souvenir d'un Ami*, *Gloire de Dijon*, *Devoniensis*, *Madame Falcot*, and *Maréchal Niel*, the last being in excellent condition in Messrs. Paul and Son's lot, the colour clear canary yellow. There was a beautiful bank of ORCHIDS in continuation of the bank of roses; and here Mr. Penny took first place with a glorious group in the class for twenty, while Mr. B. S. Williams stood first in the trade class. Mr. Young, of Leigh Park, had the best group of twelve. There were several smaller collections of great merit.

PELARGONIUMS made an extensive and magnificent bank facing the roses, and were besieged the whole day through. Mr. Turner stood first in the show and fancy classes for nurserymen with beautiful examples, and Mr. Nye and Mr. Donald took the lead in the classes for amateurs. In the show classes there were examples of *Beacon*, *Beadsman*, *Candidate*, *Garihaldi*, *John Hoyle*, *Lilacina*, *Peacock*, *Rose Celestial*, *Sir Colin Campbell*, *Osiris*, *Spotted Gem*, and *Pericles*. In the fancy classes, *Arahella*, *Goddard*, *Cloth-of-Silver*, *Crystal Beauty*, *Delicatum*, *Evening Star*, *Lady Boston*, *Modestum*, *Undine*.

HEATHS were shown in great quantities, but there was nothing new or peculiar amongst them. The best collections came from Mr. Rhodes and Mr. Peed.

STOVE AND GREENHOUSE PLANTS were also abundant, various, and fine, the subjects mostly such as we are frequently reporting on. Mr. Baines, of Bowden, Manchester, presented a grand sixteen in the principal class for amateurs, Mr. Peed the best ten, Mr. Ward the best six. In the trade classes Messrs. Lee were first for ten, and in the open class the same exhibitors took first place for six. Many notes might of course be made upon meritorious subjects, but we shall be content to name a superb *Medenilla*, one of the best ever shown, from Mr. Wilkie; a very fine *Hæmanthus punicus* from Mr. Baxendine, and some extraordinary examples of *Sarracenia*s from Mr. Baines. A sight of one pan, consisting of tall green pitchers of a variety of *S. flava*, was worth, to any genuine lover of plants, the half-guinea charged for admission to the exhibition.

NOVELTIES were not abundant, but there were some highly meritorious subjects. Messrs. Veitch presented the charming *Retinospora plumosa*, and a fine *Dracæa* called *Regina*, and a new and nice palm, *Areca crinita*. Mr. Carr, gardener to P. L. Hinds, Esq., of Byfleet, put up a fine example of *Adiantum Farlayense*. Mr. W. Bull presented a pretty group, amongst them *Tillandsia argentea*, one of the most curious of newly introduced plants, resembling a cluster of rats'-tails, all clothed with a flannelly sort of wool. This comparison is not an elegant one, yet the plant is elegant as well as curious. *Anæctochilus petala marmorea* is an elegant kind, with rather large ovate delicately marbled leaves. *Agave macrocantha* looks as if it would make a grand specimen with a few years' patience. *Maranta rosea-picta* is a pretty and apparently small growing kind, with superb crescents of rose colour on handsome dark green leaves. Mr. B. S. Williams exhibited the noble variegated variety of *Phormium tenax*, which assuredly is equal in beauty to any *Cordylina*, with other novelties; and all three of the foregoing exhibitors presented examples of *Sanchezia nobilis*. The last named plant deserves the attention of plant-growers generally, on account of its splendid character and usefulness. It is an acanthaceous plant, obtained in the first instance by Mr. Pearce in Ecuador, for Messrs. Veitch and Son. It is of robust habit, quite herbaceous, with large oblong lanceolate leaves, and an inflorescence consisting of erect terminal fascicles of flowers, with bright red bracts and yellow corollas; the bracts are an inch long, and the tubular corollas are two inches long. As each fascicle consists of nine to a dozen flowers, the appearance of the plant when in bloom is exceedingly brilliant, and in every sense distinct.

The gardens were rather dull on Saturday last, not a single bedding plant having been put out, and there are many evidences in the shrubberies of the severity of the past winter, especially amongst bays and Portugal laurels. Probably by this time the scene is changed, for a few days' work in bedding, when the season has advanced so far, produces an effect which is pleasing, if not equal to what follows when the plants have made some progress. There were 14,386 persons present at the show, and nearly all of them kept within the Palace the whole of the day.

THE NATIONAL HORTICULTURAL EXHIBITION.

The arrangements for the National Horticultural Exhibition, which is to be held in the Manchester Botanical Gardens on the 7th and 8th of June, and to continue open during the whole of Whit-week, until the 15th of that month, have so far progressed that some description may now be given with accuracy and completeness. The larger portion of the show will be held under canvas, in large marquees constructed for the occasion. The present exhibition building will be devoted to the show of orchids and stove-plants. Connected with this, by covered ways, will be two large marquees. One on the north side of the exhibition-house will be about the size of that building, and is to be devoted principally to the show of fruit. At the western end of the gardens a large plot of land has been set apart for the large marquee which will contain the greatest proportion of the flowers. This plot of land is being set out, under the superintendence of Mr. B. Findlay, in a fashion somewhat similar to the style of the International Horticultural exhibition last year, a style which proved very effective for the artistic disposition of the plants. In the centre of the plot,

which is 300 ft. long and 60 ft. wide, six circular mounds of earth have been built; each mound has three tiers, and is covered with turf. The whole show in this marquee, where the azaleas, rhododendrons, pelargoniums, and such plants will be exhibited, may be viewed in detail by the visitor taking a winding walk around these mounds from one end of the building to the other. The sides of the marquee are banked up with earth to about the height of the mounds; they are also covered with turf, but only consist of two tiers. The entire floor is level, but at the northern end of the marquee a high bank has been raised, from which a full view of the show, as a whole, may be obtained; and, to render this the more effective, the framework supporting the canvas covering gradually rises as it approaches the higher end. The exhibition will occupy altogether just one acre of ground, and the contract for the fitting up of the necessary buildings has been taken by Mr. H. Barton, of Winsford. The schedule of prizes is a very liberal one. In the amateur division there are 33 classes, in each of which three prizes varying in value from £20 to 10s. are offered. In the nurserymen's division there are 30 classes, in each of which three prizes varying from £16 to £1 are offered. There are also 17 open classes for fruits, in which prizes from 10s. up to £5 are offered. Very nearly £1,000 is to be given in prizes, of which close upon half will go to nurserymen, over £400 to amateurs, and the rest to the open classes. The liberal scale on which the prize list has been constructed may be judged from the fact that nine of the prizes are of values from £10 to £20, while 75 others are worth £5 and upwards. The publication of this list has already attracted a considerable number of entries from many of the nurserymen who so largely contribute to the metropolitan and some of the provincial flower shows. Amongst those who have already promised their support to this exhibition are Messrs. Lane and Sons, Berkhamstead; Messrs. Paul and Son, Cheshunt; Messrs. Ivery and Son, Dorking; Mr. A. Turner, Leicester; Mr. C. Turner, Slough; and Mr. Williams, Holloway. The horticulturists of Manchester, who always so well support the shows at the Botanical Gardens, will largely compete on this special occasion. Mrs. Cole and Sons, Mr. J. Shaw, Bowdon, and Messrs. G. and W. Yates, Manchester, have promised to exhibit; while from Dalkeith the Duke of Buccleuch will send a large quantity of fruit; and the Duke of Hamilton will contribute a collection of plants from his palace near Glasgow. A correspondent of the GARDENER'S MAGAZINE thus expresses his anticipations of the show:—"No doubt the plants there will be equal to those exhibited in London last year; but when we remember that some of the best collections came from Manchester, we cannot doubt the effect. It quite surprised me to see that Manchester had sent so much up, and that she had taken the laurels from the great London growers, who evidently thought no one could surpass them; but Manchester did, and great honour is due. Imagine them looking so fresh as they did after travelling 200 miles. Indeed, one would have thought they had just been taken from the hothouses. I hope the London growers will benefit by the example set them, and endeavour to help them in their great undertaking."

The gardens are now looking in very excellent condition, and during the last few days, when the temperature has been so much milder, the progress of vegetation has been almost incredible. However, by the time of the exhibition a much gayer appearance will be presented, as nearly 50,000 bedding plants will have been placed in their summer quarters. The first day of the show may almost be termed the private view, as admission will be confined to the annual subscribers to the gardens and to visitors on payment of half a guinea each. On the Saturday the price of admission will be half a crown, but during the whole of Whit-week the charge will be only a shilling. We cannot doubt that if the weather should be favourable the show will be crowded each day of that week; and we hope that the result may do much towards accomplishing the object of the promoters of the exhibition—viz., the liquidation of the debt which for so many years has hampered the efforts of the Society. Owing to the special circumstances of the case, the gardens will not be open this year to Sunday-school children.—*Manchester Guardian*.

AURICULAS IN 1867.

I had not finished my holiday in the West in time to attend the Royal Botanic Show on the 27th of April, so I lost my customary view of the new Auriculas and of the competition in old varieties. But, in order not to be quite the loser of a treat, I made a visit to my excellent friend, Mr. James Butcher, of Camberwell, on the 2nd of May, and to Mr. Charles Turner, of Slough, on the 4th. In each case I was so fortunate as to see a very large proportion of the flowers in their very best condition; some, of course, were past their best, but the loss in this respect was trifling as compared with the gain of seeing many, and those the most typical varieties, new and old, in prime perfection. This has not been a kind season for the Auricula; the winter killed many; the cold, damp spring was unfavourable to the rising of the trusses, and the burst of hot weather with which May commenced quickly finished the bloom of such as were latest in coming into flower. All highly bred florists' flowers are subject to vary much from their proper characters when the weather does not quite suit them for some time before flowering, and in many cases this season flowers that should have been smooth were rough, some that should have been large were small, some that should have been white were gray or green; yet, altogether, remembering what a trial every kind of vegetation has been subjected to, including even stove and greenhouse plants, auriculas have done so well that the experiences of the present season furnish no solid argument for the abandonment of their cultivation, even by those who have been most sorely tried. In Mr. Butcher's plants I have been interested for several years past, and have never failed till this season to attend the exhibition which takes place annually about the 25th of April at South-street, Camberwell. Mr. Butcher is a florist of the old school, and, after wearing the blue apron honourably during the term of an ordinary lifetime, keeps a few special subjects in hand for his private entertainment, and in the patriotic hope of aiding thereby to revive the taste for floriculture in the metropolis. He has, at least, done his part well, and at the annual exhibitions of the South London Society the flower is ably vindicated, and actually finds every year a few new advocates and followers. It is not a very rural spot, it is in the thick of houses and London smoke; yet the collection is a good one and is in admirable keeping, and as the plants are nearly always covered with frame-lights they are in great measure preserved from the contaminations that would otherwise result from the constant deposition of soot on their delicate foliage, and still more delicate flowers. The frames employed are ordinary garden frames, but the lights rest on cross-bars at each end, which keep them up above the bearers, and allow two or three inches of air back and front. In some cases wooden shelves are

placed stage fashion in the frames for the pots to stand upon; in other cases there is merely a bed of coal-ashes. Mr. Butcher has raised a goodly number of excellent seedlings, the result of careful crossing, and he has now a considerable number of seed-pans with little plants bristling all over them, and giving promise of work to be done, at least, if there is as yet no promise of flowers. As an old professional practitioner in horticulture, our friend knows the value of patience in dealing with seedlings. He sows in shallow pans, sets the pans on a wall, and pretends to forget them for at least a year. Then, when the soil has been soddened with rain, and baked with heat, and made mellow again by frost, he suddenly remembers them, and puts them in a frame, and hopes that spring will start the seed into activity. And it does so. I saw at least a dozen pans quite covered with little plants a week or two old, but the seed was sown a year or more previously, and the soil had become covered with a coat of moss, through which the seedlings had to push their way. After these are picked out, the soil will not be thrown away, but will be kept another year in the same pans, and then there will be another crop, the result of the germination of seeds that at present are dormant.

In looking over the blooms I noticed that selfs and green-edges were generally the best. Those that had varied most from their true characters were the whites and the grays, and the whites especially had been most punished. Worse than this, a few valuable kinds had disappeared, and not the smallest less was the original John Penn, a superb purplish blue self that was certificated in 1865. In looking over the stock, the following notes were made:—

Selfs.—Garibaldi: Good, the colour plentiful, a fine bold truss of seven. Lightbody's Meteor Flag: This opens thin, and looks queer at first, but improves, and becomes at last one of the grandest of the selfs, the colour a rich violet blue, the pip flat, the paste solid and pure; the foliage is mealy; plant a good grower. Spalding's Blackbird: Fine form, colour heavy maroon, the paste perfect; has a weak stem, but is indispensable. Martin's Mrs. Sturrock: A charming flower in form and colour, dull maroon crimson; pure solid paste; not robust, and rarely makes a big truss. *Seedling*: Blacker than Blackbird, and otherwise good. Traill's Blue Prince: Large, good violet colour, narrow but sharp paste; huge thrum; don't like it.

Green-edged.—Howard's Lord Nelson: Good every way. Lightbody's Star of Bethlehem, a fine green edge, clear violet colour, narrow paste; good. Goldham's Blucher: Not much known; large, good form; fine green edge, abundance of colour; superb. Chapman's Sophia: Sometimes classed as *gray*, but this time decidedly green; in size medium, edge broken in upon by the body colour, which is a rich purple, like that of Matilda; the thrum greenish; a grand flower; leaves serrated and slightly mealy. Lowe's Free Trade: Middling good edge, fine velvety body colour, pure paste, fine bold thrum of clear sulphur. Duchess of Oldenburgh: Rather cupped, narrow but bright edge, violet ground; good. Traill's General Neill: Large thrum, fine paste; first-rate. Mrs. Butcher: A good seedling; edge Venetian green, lively maroon colour, pure paste, large yellow eye. Campbell's Admiral Napier: A good edge, the ground jet-black, fine paste; splendid. Olliver's Lovely Ann: Still a first-rate variety, and well done in this lot. Smith's Waterloo: Pointed petals, good shape, bright pure green edge, colour dark chestnut, paste rather thin, and showing a pale lemon ground through it; not perfect, yet better finished than Page's Waterloo. Traill's Mayflower: Raised from Olliver's Lovely Ann, and differs from it only in the leaf.

Gray-edged.—Turner's Ensign: Large, stout, sharp gray edge, bold colour, bright clear paste; fine. Hedge's Britannia: Sharp narrow edge, lively violet ground; first-rate. Traill's Beauty: Sometimes a white, this time the edge greenish gray, narrow dark colour, round greenish thrum; superb. Cheetham's Lancashire Hero: Large, perfect in form, the edge greenish gray, ground black, paste circular and pure, thrum bright orange; a good grower, a brilliant flower, not surpassed even by Page's Champion. Ashley's Newton Hero: Broad edge, narrow colour, large paste; good. Headly's Charles Edward Brown: Thin edge, clear, sharp, narrow black ring, paste circular, thrum dull; a most beautiful and distinct flower. Headly's George Lightbody: Large superb edge, good colour, clear paste, bright yellow thrum; a splendid variety, no disgrace to its noble namesake.

White-edged.—Lowe's Maggie Lauder: Edge greenish white, colour regular and dark, paste peerless; a truss of sixteen flowers; quite a grand sight; to reduce them to competition 5 murder. Lightbody's Robert Traill: Thin edge, heavy narrow colour, paste extra large, gold thrum; fine. Lee's Bright Venus: The colour forms a clear ring; beautiful. Smith's Lady of the Lake: Sharp white edge, clear broad black ring of colour, pure white paste; first-rate. Lightbody's Candidate: In the style of the last; superb maroon colour, narrow edge; splendid. Traill's Rival: Large pip, broad white edge, narrow colour, fine paste; good. Taylor's Favourite: Edge narrow, scarcely white but good, broad velvety maroon ground, paste snow white, thrum clear orange; a good grower; good trusser; far better than commonly reputed, and fit for a place in the most select lot. Campbell's Robert Burns: Fine white edge, intense black colour, large thrum; a glorious flower, worthy of its honourable name. Wild's Bright Phœbus: Fit for a six, a twelve, a twenty-four, a hundred, any number, anywhere; the paste intense, almost glittering white, and a bold ring of colour. I cannot say anything about John Penn No. 2, for it was past at the time of my look over. And so now for Mr. Turner's.

The Auricula frames at Slough are placed on the north side of a big plant-house, and so are shaded from midday sun. They are of convenient size and taller than ordinary. There is an open slit front and back in the ends for the constant admission of air. The day of our visit ("our" being made out of "my" by the company of Confidante) was fine, and we were not allowed to see them till quite 4 p.m. Quite right; for the sun was blazing hot, the lights were all tilted up by means of flower pots to give extra air, and covered with a thick pattern of hexagon netting to keep the sweet things cool and quiet. But about four o'clock Mr. Ball, the genius of this department in the Slough nurseries, withdrew the nets, tipped the lights over, and presto! such a sight! I don't believe there is in the Arabian Nights a more wondrous conception of jewelry or inlaying than these Auriculas might have furnished, even to a pleading prosaist: this word is an adaptation from the French of my own, mind. However, let it suffice that the frames were crammed with specimens in perfection of bloom, the stock being elsewhere, and the seedlings elsewhere; it was like a peep into Fairyland. The show flowers were the more enjoyable because beside them were some frames filled with alpinas of superb character; in fact, Mr. Turner has worked up the alpinas to a state of as great perfection as we can imagine them capable of, though, as to perfection in flowers, we may adopt a Scripture phrase, and say we know not what a day or an hour may bring forth. I shall not attempt to describe all I saw, or all I paid special

attention to in the Auricula way. But here are a few notes that may interest the few remaining lovers of this flower, who are as priests that hold fast to a good faith that the people have deserted in a search after idols.

Selfs.—Smith's Formosa: Well calculated to attract attention, and worth more praise than growers usually bestow upon it; the fact is, auricularians are too much afraid of colour; it is a flower of good form, and the many tone of it is peculiar and refreshing. Turner's Negro is very fine for a dark flower. Sim's Eliza had gone by, but had been good; it is an advance every way on Martin's Eclipse. Sims's Vulcan has a darker colour than Blackbird, but paste not so good; it comes best when allowed to carry a large truss, so the five or seven rule is ruin to it. Spalding's Blackbird is always good; the colour firm; the paste well put on, especially in the boundary line; the form excellent. Chapman's Squire Smith: Lighter than Blackbird, and scarcely as good in the paste; nevertheless the form is good, the pip flat, the eye clear, the foliage bright; the variety altogether good and beautiful. Spalding's Metropolitan has been magnificent at Slough generally; it is not considered equal to Richmond's North Star, a well shaped blue, but it appears this season to have stolen a march upon itself; at all events, while it has been at its very best in form and paste, it has been beyond its average best in colour. Lightbody's Meteor Flag: The best of all the blues, and a great trusser; when at its best, the pip is flat and the colour rich, and it keeps a great time.

Green-edged.—Smith's Lycurgus: A bold flower; the edge a fine green, but unfortunately beaded on the margin; the colour is dense, paste good; a liberal trusser. Heap's Smiling Beauty: Bold, brilliant, and with many more virtues than vices; one of the very best in this class. Lightbody's Star of Bethlehem: Defective, but eminently showy; the edge is the worst part of it; the colour is a fine violet; the paste sharp, but narrow; the thrum very large and pale. Nice blooms, and in most cases nice trusses also, of Traill's General Neill, Litton's Imperator (a pretty small green-edged flower, rather starchy in form, the ground black, the paste round, the thrum bright orange), Olliver's Lady Ann Wilbraham, Headly's Conductor, Campbell's Admiral Napier, Howard's Lord Nelson, Dickson's Duke of Wellington, Moore's Violet, and Clegg's Lady Blucher.

Gray-edged.—Chapman's Sophia: Fine for size and quality; sometimes starchy, but not so here and now; the edge good, but a little broken in upon by the splendid purple colour; the eye pale yellow; it is one that terrifies the senior judges by its pomposity of colour, but the rising generation take to it; Mr. Ball says he never saw it so good as in 1867. Turner's Ensign: Neat gray edge, broad purple colour, good paste. Read's Miss Giddings: A sensation flower; rough, but flat; plenty of colour; well proportioned; small thrum. I measured a pip of this, and found it exactly an inch and a quarter in diameter. Lightbody's Richard Headly: Beautiful in form, broad gray edge, colour black, well defined, paste somewhat angular, eye orange; a fine thing. Good examples also of Lightbody's Alma, Waterhouse's Conqueror of Europe, Dickson's Duke of Cambridge (is this a gray or a green edged?), Cheetham's Lancashire Hero, Fletcher's Ne Plus Ultra, Grimes's Privateer, Lightbody's Sir Charles Napier (large, comes near to Conqueror; inconstant, this year fine), Headly's Superb, Headly's Stapleford Hero.

White-edged.—Ashton's Bonny Lass: An immense amount of white about this flower; the size medium, edge far from perfect, but bright; colour nicely laid on in a narrow black ring, broad white paste; very attractive. Lee's Earl Grosvenor: Large, round, smooth, huge truss, pure white edge, pure black colour, broad paste, greenish thrum, leaves large, gray, and drooping; this is a neglected flower, of better quality than commonly reputed; I see it priced in the catalogue at 3s. 6d., yet there are people who will pay ten pounds for a bit of paltry jewelry, which never changes except to lose its lustre, and become unfashionable; and pass by such a bit of everlasting jewelry as this, wrought by the hand of God, and capable of a hundred changes as the year goes round, but incapable of parting with its primal lustre. Taylor's Glory: This is called Glory because it is Glorious, and the man who is not proud of such a flower, whether raiser or cultivator, ought to be—but never mind, we will consider what should be done with such an ineptus. The edge is exquisite, and is really white; the colour is delicate and delightful violet; paste as it should be; mealy foliage. Hepworth's True Britain: Large, rarely opens flat, edge white and faultless, ground dark purple, paste circular, thrum clear orange, bold handsome foliage; one of the best whites. Fine examples also of Taylor's Favourite, Campbell's Robert Burns, Ashworth's Regular (one of the best), Summerseale's Catherine, Lightbody's Fair Maid (lovely, but too fond of flitting), Smith's Ne Plus Ultra, Traill's White Rival, Smith's Lady Sale (fine), Clegg's Crucifix (coarse, bold, and showy), Lowe's Maggie Lauder, Popplewell's Conqueror.

Amongst the new varieties I made special notes on the following:—

Unexpected (Turner).—Broad dull green edge, moderate black colour, good paste, large thrum, green leaves; good.

Colonel Champeys (Turner).—Narrow clean gray edge, colour purplish blue, broad and good, paste clear white, thrum too pale. Flowers finely formed, stout, and in a handsome truss.

Charles Turner (Turner).—Finely formed, stout and flat, edge narrow, clear gray, bold violet crimson colour sharply defined, paste pure and circular, thrum yellow; first-rate.

Cheerfulness (Turner).—Large, well shaped, scarcely smooth, rosy purple self, with beautiful white paste; good.

Crown Prince (Turner).—First-rate form and substance, combined with size and smoothness, self coloured deep crimson, with shifting shades of indigo, and excellent paste; a very fine flower, the exact colour of which cannot be determined, as it varies with age, but is always good.

The Alpines presented a lovely appearance, and it may be concluded, by the large number grown, that they are rising in favour, which they well deserve to do. No raiser in modern times has dealt with these so boldly and successfully as Mr. Turner, and the Slough collection is remarkable for variety and quality; nowhere else is there anything like it. The question necessarily arises whether we are doing justice to this race in the framing of schedules, and in our public criticisms on matters of floral taste. I am afraid we are shamefully neglectful of them, while wasting strength and means on subjects far less worthy.

Defiance.—Richest crimson shading to maroon, gold yellow paste; the best formed of all the alpinas with the exception of John Leech.

Selina.—Large and smooth, soft rosy purple, white paste; fine.

Brilliant.—Richest maroon, and clear yellow paste.

Helen.—Rather pin-eyed, but grand for size and form, colour rosy purple shading to crimson, large sulphur paste.

Starlight.—Maroon and purple, paste clear jonquo yellow.

Constance.—Indigo purple and straw paste; very beautiful.

Christine.—Rather cupped, bluish purple, pale straw colour; second-rate, yet very pleasing.

Vivid.—Crimson purple and gold yellow; a splendid flower.

Minnie.—Purple shading to lavender, pale yellow paste; fine.

Beatrice.—Superb form, shaded purple, fine solid pale straw paste.

Eclipse.—Purple shading to blue and crimson, the paste clear sulphur.

Field Marshal.—Maroon shading to black, bright gold paste; splendid.

Satan.—Broad rich maroon colour, clear sulphur paste; a fine flower with a bad name.

Novelty.—Purple shading to rosy purple, the paste primrose; very pretty.

Bertha.—Rich purple shading to blue edge, paste primrose.

Venus.—Large, fine form, broad purplish maroon colour, gold yellow paste.

Lustre.—Large, stout, and smooth, colour crimson deepening to black, bright yellow paste; extra fine.

Constellation.—Larger than Lustre, and in the same style of colouring, yet distinct, especially in the colour, which is darker within and brighter without; extra fine.

Echo.—Large, finely formed, quite smooth, colour rich crimson shading to violet, paste primrose, and not enough of it.

Fascination.—Beautifully formed and finished, colour very dark shading to pale violet, paste pale sulphur; first-rate.

President.—Dark crimson shading to fiery crimson, paste gold yellow; a rich, lively, finely finished flower.

Princess.—Fine dark colour shading to violet, with white paste; novel and pretty.

Trumpeter.—Large and handsome, but wanting finish, colour in three shades, that within being deep red, next rosy crimson, margin reddish orange or buff, paste yellow; a showy and novel style of colouring, and likely to lead to the establishment of a new class.

Jessie.—Crimson shading to violet, paste yellow; pleasing, but second-rate.

At the time of our visit the tulips were in full bloom, being many days in advance of their ordinary season at Slough. It was a good bloom, though the flowers were in most cases wanting in size, as might be expected, as the result of the forcing weather by which they were hurried. Carnations and picotees looked well, and there was an immense number of them. As for other departments, they were all in the smart trim proper to the place. Many proofs that the last was a bad winter were to be seen amongst coniferous trees and roses. The houses and pits devoted to pelargoniums, comprising all known classes, were full to repletion, and the specimens intended for exhibition were on shelves high up near the glass, with air and light all round them, making themselves finely for the day of triumph. S. H.

NOTES ON THE EXHIBITION OF TRICOLORS.

Having entered the garden by way of the Queen's Road entrance, my first glimpse of the exhibition was a miscellaneous collection of plants by Mr. B. S. Williams, of the Victoria Nursery, Holloway, in the western arcade. As but few persons were attracted to this portion of the exhibition, I had a capital opportunity of observing, according to my judgment, their respective merits. We have been accustomed as each season revolves to behold at our leading metropolitan exhibitions the same varieties more or less in every collection, so that wherever there is a freshness of subjects introduced (apart from novelty) we feel our interest revived. One of the most noticeable features in Mr. Williams's lot was a variegated pine named *Ananas sativus variegatus*, producing a fine fruit; this had a very pleasing effect set in the midst of flowering plants. There was also a fine plant of *Imantophyllum miniatum*, having splendid trusses of bright orange coloured flowers. The remainder consisted of azaleas, aphelexis, and other showy stove and greenhouse plants. As a kind of bordering to this collection were two rows of variegated Geraniums in pots, among the most remarkable of which was *Annie Williams*, having a very distinct appearance to the generality of the above section; also by the same exhibitor was a variety named *Brilliantissima*, a great improvement on that very old favourite "Brilliant." A collection of varieties of British ferns, consisting of upwards of forty varieties, were uncommonly clean and healthy. There is great beauty and interest attached to this class of plants on account of their curious structure. They may vie in graceful appearance with many of the more rare and expensive exotic ferns, and are far more useful for general purposes, especially for the very many conservatories that are affixed to most of our villa residences, and which are, as a rule, deficient of good heating apparatus, so that the hardier the constitution of the plants the better are they adapted for furnishing these houses.

We have now before us a collection of Standard Zonale Geraniums, exhibited by Mr. William Paul. They consist of the most popular varieties that have been sent out by that gentleman, with specimens of Mrs. Pollock and one or two other Tricolor varieties added. We are led to ask to what use can we turn this style of growth. They may, like our tall plants of chrysanthemum, that are cultivated for the purpose of large or monstrous blooms, be well adapted to be intermixed with azaleas and other large plants that are past bloom, as the heads of the zonales when in flower can be so arranged as to be visible just above the foliage of the others, thus producing a very glowing effect when otherwise the house would have a sombre appearance. In front of the zonales was an immense bush covered with huge clusters of flowers of that lovely variegated plant *Hydrangea hotensis variegata*. Also from the same exhibitor a most interesting and beautiful collection of variegated Ives and Aucubas. Surely the time has arrived when we can have such a choice of refined, and I may say without exaggeration very chaste foliage plants presented to us, and that at moderate prices, that important improvements may be made in the planting of parks and gardens. In this advancing age, the time ought to have arrived in gardening when the barbarous sameness produced by the crowding in a given spot of a quantity of some free growing evergreens or trees, with the view of realizing immediate effect without any regard to refined taste, should be abolished. As we shall have the new Hall of Arts and Sciences so closely connected with our national Horticultural Society, it is to be hoped that the science of gardening will there find a refuge for its future development.

Passing a collection of some well-flowered Ericas, and other greenhouse plants, exhibited by Messrs. F. and A. Smith, of Dulwich, we have now arrived at an exhibition of the principal features of this day's show, that is, a vast number of Tricolor Geraniums by that great vendor of new plants, Mr. Bull, of Chelsea. They were apparently seedlings, being very small

plants, in groups of threes, plunged in large pots, the surface being mossed over so as to give them a clean and neat appearance. Although there may be some extra superior sorts amongst this collection, yet to my fancy the most distinguishable was a very neat and highly attractive silver-leaved Ivy Geranium, with a profusion of light pinkish flowers. It will, no doubt, make a first-class bedding or edging plant for a ribbon border.

We come now to a further lot of larger plants of the Tricolors. Beside them was a fine collection of foliaged plants; both being exhibited by Messrs. E. G. Henderson and Son, of the Wellington Nursery, St. John's Wood. Among them were two very attractive varieties—viz., *White Lady*, of the silver-leaf type, a very free bloomer; also *Queen of Nosegays* and *Rosetta*. The last named was a very desirable variety, and evidently a very free bloomer, as it exhibited a quantity of delicate rosy pink flowers. But more noticeable for splendour, in the contributions from the Wellington Nursery, were those superb Tricolors *Lucey Grieve*, *Sophia Cusack*, *Sophia Dumaresque*, *Sunshine*, and *Lady Cullum*. The first and last named of these five are perhaps the most magnificent Tricolors in existence. From the same firm came a collection of miniatures, adapted, no doubt, for edgings, as they are of very compact habit, and have brilliant colours. The best of these were *The Bride*, *Golden Pet*, *The Fairy*, *Queen's Favourite*, and *Minnie*.

We have now come to the last collection of Tricolor Geraniums in this portion of the exhibition. They were from Messrs. F. and A. Smith, of Dulwich, consisting of upwards of forty varieties, many of them being seedlings, as yet not advertised for sale. There was a peculiarity about these plants which I cannot refrain from noticing, and that was the remarkable freshness which pervaded them, thus assisting very much to bring out their true characters and colours. Messrs. F. and A. Smith are, in their perseverance to obtain new varieties, endeavouring to associate with them leaves of a convex form, so that they may be more readily cleansed of any dust, or other foul matter that may be deposited on them, thus enabling them to be bedded out with a great certainty of preserving their freshness of colour, in and near large towns. In this collection were some most striking varieties, such as *Mrs. Dombain*, *Vivid*, *Impératrice Eugénie*, *Champion*, and many others. Amongst other kinds I made note of as good, the following I think deserve particular mention. From Messrs. Garraway, of Bristol, *Mrs. Allen*, with gold yellow margin, and bright crimson zone. From Messrs. Carter and Co., *Prince of Wales*, which has very large leaves, and a stately habit; the leaves quite flat, and most richly coloured gamboge yellow, with bright red zone. From Mr. Grieve, *Victoria Regina*, of the most vigorous habit of growth, and the one which Mr. Grieve, the father of the family, considers the best Tricolor he has yet raised. Messrs. Saltmarsh sent a Tricolor called *Sunshine*, very neat, very bright, and a good grower. Mr. Groom, of Ipswich, sent *Lord Stanley*, a first-class sort; and Mr. Chater, of Cambridge, had his famous *Senior Wrangler*, the fame of which is well established.

As we arrived rather late, we hasten on to catch a glimpse of the principal portion of the exhibition, which was held in the Council Chamber, passing on our way through the conservatory, in which there were various collections of greenhouse plants, exhibited by our principal growers; but as these will be duly reported at our forthcoming exhibition, I did not stop to notice them. However, my attention was arrested by a quantity of a new variety of Pyrethrum called *Golden Feather*, the leaves being of a yellow or gold colour. Beside these, were samples of the graceful but delicate grass *Poa trivialis variegata*; both these plants are well adapted for edgings. They were exhibited by Messrs. E. G. Henderson and Son, St. John's Wood. JOHN F. M'ELROY.

GELDING OF CITROUILLES.

Few will believe at the first blush that "caponage" is practicable upon gourds; but nevertheless the fact is announced as true. The Maréchal Vaillant gives an account of this proceeding, which was communicated to him by the captain of a vessel returning from Senegal, where the negroes have been in use to practise it from time immemorial. The operation consists in making an opening at the top of the fruit while it is still young, and adroitly removing the ovules or undeveloped seeds. The wounded part is closed, and the cellular tissue of the fruit then takes a prodigious increase, and a greater fineness of flesh.

M. André, who communicates the above fact to the *Revue Horticole du Monteur*, says truly that it appears quite rational, although received from the Yolofs and the Bambaras, and is in perfect conformity with the laws of physiology; and the *Belgique Horticole*, in commenting upon it, suggests that the experiment should be extended to melons and other gourds.

One thing is clear, that it is very easily tried, and the notice comes quite in good time to allow every one to try their hand upon vegetable marrows, citrouilles, and melons, during the coming season.—M., in the "Farmer."

GOUGH THE BLIND BOTANIST.—The perceptive power which resided in that accomplished man's touch was amazing and almost incredible. It is exquisitely expressed by his friend Wordsworth in a few lines of the "Excursion":—

"No floweret blooms
Throughout the lofty range of these rough hills,
Or in the woods, that could from him conceal
Its birthplace; none whose figure did not live
Upon his touch."

Wordsworth once brought to Mr. Gough a cushion of moss-like leaves angled with bright purple flowers from near Griesdale Tarn. When Gough touched it he said at once, "I have never examined this plant before, but it is *Silene acaulis*." We feel this to be one of the most charming of Westmoreland anecdotes, whether we consider the beauty of the flower itself, or of the scene from which it was brought. But it should be added that Gough's science was not by any means limited to natural history. He was eminent also in physics and in mathematics. Dalton and Whewell were among his pupils.—*Quarterly Review*.

DESTRUCTION OF SEA-BIRDS.—Will you allow me space to make the remark that the secret of the bird-slaying on our sea-coasts, so ably denounced by the Rev. F. O. Morris in your columns a short time since, lies chiefly in the fashion, now so prevalent among young ladies, of wearing the plumage of sea-birds in their hats? Many words surely cannot be needed to induce at least the more thoughtful among them to discourage a practice which is often attended with cruelty, and which must result, if persisted in, in the almost total disappearance of one of the most interesting classes of objects which our shores present.—B. P. P., in "The Times."

Scale, 1-18th of an inch to 1 foot.

PLEASURE GARDEN AT "THE LAURELS," TAUNTON.

A HOLIDAY IN THE WEST.

PART II.—THE LAURELS, TAUNTON.

Plans and descriptions of small gardens are probably of much more value to the general public than plans and descriptions of gardens of great dimensions. For one who intends or desires to embellish a thousand acres, there are at least a thousand interested in the embellishment of two or three. Therefore, in presenting a plan and some few particulars of the pretty garden of my friend J. B. Saunders, Esq., "The Laurels," Taunton, I suppose I am contributing directly to the end for which the Magazine is purchased and perused by its thousands of supporters. This garden comprises in the whole

about three acres of land, only part of which—the pleasure garden—is shown in the accompanying diagram. The dwelling-house abuts on the high road, which here takes a bend to the right, and decides the boundary line, which is shown as a curve on the left hand of the diagram. This boundary line is defined by a low wall. On the right hand the garden is separated from the next property by a fruit-wall, which is seen as a straight boundary line on the right hand of the diagram. The boundaries of a small property greatly influence the plan of laying out and the style of embellishment adopted. In the case of a large property, the boundaries may be treated with indifference; we scarcely need know of their existence in designing the more important of the decorative features. In the case before us, elegance and

richness without harshness are combined with strict formality, and the result is as pretty a pleasure garden of its size as I have ever seen, though not deficient in experiences in these matters. The main walk down the centre is spanned by three wire arches, over which are trained clematises and roses. The two grass-plots on the right and left of the walk are on a higher level than the walk itself, the grass rising from the gravel by an easy slope, which contributes greatly to the improvement of the perspective, as looking along the walk we see the gravel bounded on either side by a soft swell of turf in place of the customary hard line. There are six groups of beds on the grass, all different, yet nearly corresponding in style, the groups being in pairs right and left, matching without repetition, thus affording variety without the usual doubling over, yet without violating the formality essential in a garden of this kind. A few beautiful coniferous trees, planted in pairs near the walk, assist greatly in adding to the richness and variety of the scene, and in relieving the flatness of mere grass and flowers. During the summer some fine variegated aloes are placed on the pedestals which are shown on the plan, and these add finish and stateliness to the general effect. Under the boundary walls are borders, which have hitherto been planted ribbon fashion; but the right-hand border is now to be devoted to a mixture, in which choice hardy herbaceous plants will predominate, this being a rather shady border, in which hitherto bedding plants have not done well. At the lower end of the garden, the gardener's residence occurs on the right hand, and a conservatory on the left. The frontage of the gardener's cottage is towards the kitchen garden; and on the high wall which separates it from the pleasure garden is a grand apricot-tree in admirable condition, and the short border in front is occupied with anemones, ranunculuses, and mixtures.

I propose now that we take a walk together, and of course we start from the dwelling-house. On the slip of grass with which we begin—that is to say, the grass-plot next the house itself, and which is divided by the main walk—there are some standard roses, with grass close to their stems, in a very poor condition, and just illustrating one of the major canons of the "Rose Book" to a T, or to any other letter that may stand for exactitude. But ample amends is made for this unwelcome feature. There is a clump on the plan marked "rockery," letter G. That clump consists solely of one huge plant of Pampas grass, planted on a mound, which is faced with blocks of stone. At any time from the middle of May till severe frost has occurred in the following winter, that pampas is a glorious object to behold. It is of gigantic size; it is mounted high enough above the level to show its elegant arching outlines to perfection; and its long leaves just touch the grass turf below them in a great circular sweep of sublime proportions. This plant flowers profusely every year, and I am afraid to make a guess at the average number of its flower-spikes. At the angles of the walks there are two Portugal laurels of gigantic dimensions and faultless beauty—miniature mountains of glossy dark green leafage. Now we enter upon the principal length of the walk down. We see nice examples of *Abies Douglasii*, a remarkably dwarf close-branching and robust *Araucaria imbricata*, *Cedrus deodora* of course, *Picea pinsapo* in beautiful condition now, but the marks of injury by the past severe winter just traceable at the junction of the new and the old wood, very many of the terminal buds having been destroyed.

The geometric schemes look better on paper than on the ground. The garden measures 184 feet in length, by 116 feet in greatest breadth, dimensions insufficient to bring out so complicated a scheme as the principal one on the right-hand plot, lettered A. That, however, is a good design in itself; and if it could be drawn out so as to occupy nearly the whole area of the garden (which, of course, is impossible), it would be grand; but as I view the scene, the design appears contracted and wanting in dignity. The scheme B is open to the same objection; C and D are much better adapted to the space; but E and F are still better adapted, and, in my opinion, E is at once the most effective and satisfactory of them all, and quite a model design for a bedding display in a small garden. I may be able hereafter to give the colouring of these beds for the present season and for some years past; for the present I shall take occasion to say that my friend Mr. Saunders is an able colourist, and throughout the summer these beds are gloriously brilliant with skilfully harmonized colours. In the autumn of 1866 I saw the garden at its best; and in the ribbon on the left hand border *Iresene Herbstii* was then superbly rich, and had made a robust growth, unhurt by weather or vermin. The planting of the two principal schemes this season consists of mixtures, and I am strongly inclined to believe that these mixtures are at once original and effective, and suitable to afford suggestions to all who are concerned in garden colouring. But for proper judgment of the case we must wait; and I hope to see this pretty garden again before the summer is over and gone.

The plant-house, 40 feet in length, which embellishes one side of the garden at the lower end, is furnished with valuable and interesting subjects. Here are not only good examples of the flowers of the season, whatever the season may be, brought forward from the pits and greenhouses lower down, but a few fine permanent occupants in the shape of palms, tree-ferns, a few good climbers, and miscellaneous hard-wooded plants. On the other side is a high wall which screens off the gardener's cottage from view, and affords accommodation for a fine apricot tree, which, on the 20th of April last, was sprinkled all over with fruit of the size of hazel-nuts. The gardener, Foulger, called my attention to the difference between this and another fine old tree in equally good health. This had no fruit at all, or so few that it would need a diligent search to find them. These trees came into flower during the horrid weather that followed the 20th of February last: one was either dripping wet or frozen during the whole time the flowers were open; the one that bears so good a crop was wholly unprotected, the other and barren tree was taken great care of and had abundant protection, but was not buried in blankets, in fact, was protected judiciously. This is a parallel case to that related by Mr. Clarke in his report on Knowle Park in last week's Magazine.

The kitchen garden, which is entered by the gate between the greenhouse and the gardener's cottage is admirably arranged and kept. The main walk is made interesting by a line on each side of bush pears five to seven feet high, which during the three days on which I saw them, April 18, 19, and 20, were in perfection of bloom, and some of them almost as fragrant as thorns. These trees are mostly on pear stocks, have never been pinched, but are pruned in winter moderately, and the quantity of bloom upon them was enough to satisfy the most exigent of the practitioners of pinching. They put me in mind to say that the trees in our fruit garden at Stoke Newington were sadly neglected; last year not one was pinched, and the only winter pruning consisted of a moderate shortening of the longest rods, and the bloom on the trees was so dense that they were like pyramids of snow; more than this, our trees are abundantly covered with fruit, which is not generally the case with pear-trees this year, a fact which we attribute to the kindly shelter afforded them by St. Mary's church. So far in illustration of the pinching system. I wish to be understood as saying nothing at all about it now *per se*; I am simply recording a fact. Now, as to climate, on the

19th we had for dinner most excellent asparagus from the open ground, cut short and green, with not an inch of white upon it, and all edible, delicious. The asparagus beds at Stoke Newington did not present a visible shoot till the 30th of April. Another agreeable evidence of the better climate here than in the neighbourhood of London was the generally forward and thriving state of peas, beans, onions, and other early sown cuculents, which with us were at that time perishing of cold. Raspberries were already showing flower-buds, and lettuces and cauliflowers were growing with vigour. There is a pretty and useful range of plant houses at the lower end of the kitchen garden, in great part (then) occupied with bedding plants; but there are also collections of ferns, begonias, gloxinias, achimenes, and other interesting subjects, from amongst which Mr. Saunders will make selections for the Taunton flower show when the proper time shall come. Indeed, the people of Taunton were largely indebted to this garden for the splendour of the exhibition held last year, but still more to its proprietor for the spirit with which he led the way, and did the hard, rough work of honorary secretary, and secured for the enterprise the most complete and brilliant success. To enumerate the various subjects to be found in the houses would not be prudent while we have so many and such pressing demands on our space as now; but I am bound to place on record that there is here a silver tricolor geranium which far surpasses *Italia Unità* as a bedder, but the proprietor will not part with it for love or money. S. H.

A CALL AT MR. B. W. KNIGHT'S NURSERY, BATTLE, SUSSEX.

I had a particular desire to call upon Mr. Knight, because I wished to collect further information respecting that useful early strawberry *The Princess of Wales*, raised by him, and I had the satisfaction of seeing good breadths of it in a promising condition. I saw not only the parent plants, but the first progeny of them maintaining its character in every particular. As this variety is steadily working its way into public favour, some information as to its origin may be interesting. In the first place, I learnt from Mr. Knight that he never fertilizes anything, and that all his novelties are selections, the *Princess of Wales* strawberry being no exception to the general rule, and in this instance it was the result of a choice of one amongst only four fruit that were brought to him while confined to his room by a severe illness, now eight years ago. Not knowing from which of the many varieties which he cultivates (sixty in number) the fruit brought to him was gathered, he selected the most distinct and promising, and sowed the seed, and the result was the production of the variety now under notice, and of which he speaks in his catalogue in the following terms:—"This superb variety is now proved to be the best early kind hitherto produced, being fit to pick twelve days before any other kind. The fruit is large, many of the berries weighing over an ounce each. The flesh is of a pale red colour, solid at the core, flavour rich and sugary, partaking largely of the pine flavour, and the plant an abundant and sure cropper." The above description I believe to be a faithful one, from the fact that its truthfulness is borne out by the evidence of several good gardeners, and amongst them we had last year that of Mr. J. Rust, of Eridge Castle, who was not only growing it largely for forcing, but was actually rooting out all other early varieties in favour of this one. I am interested in this strawberry only from the fact that I have been asked several times to decide upon its merits as an early strawberry, when, in fact, it was not to be found on the spot, but a substitution of Ingram's *Prince of Wales* sent in its stead, to the manifest disappointment of the cultivator. This, I was also assured by Mr. Knight, had been so often the case that the sale of plants had been somewhat impeded by it. Another remark Mr. Knight made verbally to me, as to its character, I think ought to be in the reach of cultivators. He says that it requires to be renewed by fresh plantations made every third year. But what has influenced him in arriving at such a conclusion I have no means of judging, nor have I yet seen or cultivated it long enough to feel justified in giving a confident opinion upon that matter of detail. But, judging from the condition of the parent plants, and the first runners from them, which are still luxuriant and healthy, although they are in a rough state, owing to the ground on which they are standing being required for building, I feel disposed to differ from him in that matter, as I believe that, if they are as carefully cultivated as the rest, they will continue to fruit abundantly for more than three years. But still the opinion of the raiser is to be accepted with every confidence as the result of a longer experience than any one else has yet had with this particular variety. It is also most creditable to the raiser, as it is a pleasure to me to report such a conscientious assertion from one who, above all others, is most interested in its distribution, and the reader may accept it as strictly conveying the character of the individual from whom it was made, as he is not one of those men who gets his finger in the button-hole of your coat, and compels you to stay until he has dinged into your ears a glowing description of all his novelties. But, on the other hand, he appears only interested in showing them to you, and letting you judge for yourself of their particular merits.

For the second time since it was sent out, I met here that dwarf bedding *Ageratum Prince Alfred*. I noticed the same variety last year, in my report of Eridge Castle, by the name of the "Prince of Wales;" nor did I know but what I was correct, as it was the name given me, until Mr. Knight corrected me, and at the same time informed me he was the raiser. Many inquiries have been made as to where this variety could be got, and I hope this notice of it here will put the inquirers in possession of the information, as Mr. Knight has generally a good stock on hand.

There is still a greater novelty than *Prince Alfred* amongst *Ageratums*, by the acquisition of a variety, almost miniature in size, called *Little Pet*, never exceeding eight inches in height, more generally six inches, completely covered with bloom. I saw a lot of young plants in thumb-pots; at the tip of every bit of growth was a bunch of flowers showing.

Mr. Knight's *Lobelia White Lady*, with the habit of *Paxtoniana*, is evidently an improvement on any of the same habit; and should the report be true that "Miss Murphy" is not a continuous flowering subject, or that its flowers are confined to the first part of the season, *White Lady* is destined to occupy a prominent position in the flower garden.

I took note also of two new *Helichrysms* treated as perennials; they were improved varieties of *H. macranthum compactum*. The variety called *Alexandra* is a deep rich crimson; *Albert Edward* is a rich scarlet, and blooms freely. The treatment of these plants as perennials will be new to most of the lovers of everlasting flowers. Amongst seedling geraniums I saw a few good things. The most remarkable was a bright silver-edged variety that must take first rank amongst the bedders at no distant date.

As a remarkable instance of the capability of some plants to endure frost

that we least expect, is the fact that *Alyssum dentatum* has stood out here in the open border without any protection, and the past terrible winter has done it no harm.

As Mr. Knight is an extensive grower of strawberries, I am induced to return to them again, to give the reader his opinion upon the advisability of manuring them in autumn. He says autumn dressings cause the buds to rise prematurely, and owing to their being in a growing, succulent condition, the frost has more effect on them; consequently the flower-buds perish, and thus barren plants are created. All those who are interested in strawberries will do well to pay Mr. Knight's establishment a visit from the latter half of June to the middle of July.

J. C. CLARKE.

"A WORD IN SEASON" ON BEHALF OF SMALL BIRDS.

By the Rev. P. DE PUTRON, M.A., Rector of Rodmell.

The mischief done by birds on a fine summer's morning is, alas, so visible and so irritating to farmers, gardeners, and cottagers, and the good they do early and late so invisible to the untutored eye, that their death-warrant is sealed at once, without the hope of a reprieve or recommendation to the majesty of mercy. Yet experience proves that the presence of birds in our corn-fields and gardens is highly to be desired. We have only to cross from Newhaven to France to lament, as all travellers do, the marked absence of small birds from the landscape, and to learn from our companions how keen is the regret, which too late invokes the protection of the law for the feathered guardians of the fields. The following testimony to their value is taken from a public report which was laid before the French senate, and will doubtless be read in Sussex with such interest as the case deserves:—

"It is solely in the interests of agriculture being very seriously endangered, that they affirm that men ought not to be allowed to continue to destroy the only auxiliaries which can effectually stop the increase of insects, the bane of all cultivation. Against such enemies man is powerless, and if God, in His wisdom, had not provided a remedy, vegetation would have disappeared from the face of the earth.

"This providential mission of birds was, for a long time, considered an exaggeration; now it ranks as one of the best proved truths of science. Yet man, by a strange blindness, shows himself the most terrible enemy of these gentle and useful creatures.

"More cruel than the kite or hawk, who kill to feed, he destroys them for the simple love of destruction. The gun is not murderous enough, it is by all sorts of contrivances—such as nets, bird-lime, traps, &c.—that these charming and indispensable little friends are persecuted by man, to whom they were given by a wise Providence. The amount of mischief done is incalculable. Let us look the matter in the face; the evil is great, and if we do not take care it will be beyond a remedy."

So speak our French neighbours, and add, that in one of the Eastern departments the value of grain destroyed by insects in one year was estimated at four millions of francs, or £160,000!

With this warning before our eyes, we shall do well to pause in that wholesale destruction of birds in which the members of sparrow-clubs so largely indulge. Still, it is only fair to say that these relics of a barbarous age are gradually dwindling away before the warm-hearted and growing intelligence of yeomen, and respectable newspapers are becoming ashamed to chronicle these periodical massacres.

A Country Clergyman, who has written some very good words for poor birds, states "that the sparrow probably bears the worst character of all our common feathered friends, and is consequently the most persecuted; and yet a pair of sparrows have been known, during the time they were feeding their young ones, to destroy every week 3,300 caterpillars! If this result could be achieved by two birds, let our young readers estimate, if they can, the weekly work of the feathered tribe. The goldfinch also stands in need of friends to protect it from the treacherous bird-catcher. The seeds of dandelion, groundsel, thistles, and other noxious weeds, are its usual food, and yet we hear of the enormous number of 13,818 goldfinches being sent from Worthing in a single year.

Who has not seen the startling perched on the back of a sheep, devouring the insects which, to use a local word, *terrify* the poor animals, and then finishing its meal on wireworms turned up by the plough? The services of rooks are now more civilly recognised, and instead of shooting them, as of old, a small boy with a loud voice may be both seen and heard discharging volleys of *shouts*, not *shots*, with marvellous effect, in defence of the sprouting corn. Yet that atrocious and cowardly modern invention of poisoned wheat bids fair to lessen these useful birds. Some years ago in Hampshire a war of extermination was waged against them, and rookeries were destroyed; the natural consequences soon showed itself in such an increase of various hurtful insects, and especially of the cock-chafer (which is three years in the grub state, and all that time does an immense amount of injury to the roots of grass and corn), that women and children were obliged to follow the plough to pick up these grubs, which the rooks would have devoured had they not been murdered. This practical proof of the utility of rooks opened the eyes of the Hampshire farmers, and rookeries were again established, and rooks protected. The same thing happened in America, where at one time the State offered rewards for their destruction, and in consequence they so much decreased, and noxious insects so greatly increased, as to induce the State to offer a counter-reward for their protection.

Not one word only, but many earnest words of appeal and remonstrance, might be written, too, on behalf of the thrush and blackbird, in spite of their persevering onslaught on our tempting cherries and currants in summer. Are they to be murdered for this, when an old net suffices to guard our garden treasures? And shall we plead in vain for the insect-eating birds, such as swallows, martens, swifts, wrens, robins, and black-caps? The list is by no means complete, but I bold a brief on behalf of at least fifty families of feathered clients, who either periodically visit or permanently make England their home.

"Live and let live" should be our motto, and the lesson of mercy and loving-kindness should be inscribed on the walls of country schools, and engraved on the hearts of town and country children among their earliest recollections. So different, alas, was the feeling not a century ago, that the cruelty of taking nests and destroying the eggs and young was encouraged by many churchwardens, and head-money for sparrows not unfrequently figured as an item in their accounts.

Well may it be asked, How long will it take to unlearn this cruelty, which has hardened the hearts of generations of children, and to propagate

the seeds of compassion and tender-hearted kindness towards all God's creatures?

Old traditions are not easily uprooted, as this single fact will show, that during the late frost a party of three *sportsmen*! from Brighton boasted that in one day they had killed 1,700 larks. My informant cries shame! and thousands cry shame! nevertheless I have faith in the manliness of Englishmen, and trust to the brighter intelligence of the 19th century to impose an eternal veto on such unfair and unmanly dealing with harmless birds.

"Can we wonder," says Mr. Roach Smith, with undisguised alarm, "at the increase of the insects which destroy our fruits, and at the great loss sustained by those who have extensive orchards and gardens? The birds are the only possible agents to counteract the deadly unseen insects which are, every hour, being bred almost everywhere. Nature has formed the bird's eye for detecting insects where the eye of man is useless. Wholly destroy the birds, and the fruit is wholly destroyed. At Hartlip, some years ago, in the face of truths and facts, the sparrows were exterminated entirely as being injurious. The orchards were immediately covered with the webs and nests of innumerable caterpillars and other insects; and in two years it was calculated that over £1,000 was lost in consequence of this insane slaughtering. But far more startling instances could be adduced; and yet we see no steps taken to stay the evil! I, sir, look more to youth than to the hardened man, who has steeled himself into erroneous convictions, and will never part with them but with life. It is not so with boys; they are to be reasoned with; and if the clergy and schoolmasters would make friends of them, and explain the nature and use of birds and their importance in the great scheme of Providence, I am assured they would soon be induced to be protectors instead of destroyers of the birds; and they would thus find doing good much more grateful and profitable than working evil."

If our cause were as weak as it is strong, it could be propped up triumphantly by recent intelligence from New Zealand, that the colonists are ready to pay one pound sterling for every insectivorous bird that is landed alive in the colony. And why is this? Why their anxiety to purchase for gold the little birds whose value is so little understood in England? The reason is, that Australia and New Zealand are becoming corn-growing countries, and absolutely require the services of birds to destroy the worms and insects which invariably appear wherever wheat is grown. The eggs and grubs of these destructive creatures are introduced into the colony with the seed, and thus it is a wise provision of a merciful Providence that birds should find a home, and justly claim protection in all places where they can benefit man, by obeying, for his good, their natural instincts.

I commend this subject to the consideration of all parents, teachers, and inspectors of schools, and am not without hope that these remarks may tend directly or indirectly to encourage the growth of the best feelings of the human heart whilst they enlist the sympathy of all, in holding sacred even the life of a little bird.

How can I teach your children gentleness,
And mercy to the weak, and reverence
For life, which, in its weakness or excess,
Is still a gleam of God's omnipotence,
Or death, which, seeming darkness, is no less
The self-same light although averted hence,
When by your laws, your actions, and your speech,
You contradict the very things I teach?

LONGFELLOW.

NOTE.—A severe penalty has been made necessary to prevent the destruction of these useful creatures in France and Germany. [The foregoing tract forms No. 45 of the collection of the Royal Society for the Prevention of Cruelty to Animals.]

ABOUT PLANTING.

Not the entire theory of flower garden decoration, nor any part of the same, nor the theory of planting the whole or any part of a kitchen garden, or any theory at all; but a few words on the process, pure and simple, which generally goes by the phrase "sticking them in." To be candid, I must confess that I am very vexed in that we shall have few enough of cauliflowers this summer, and those quite late enough and bad enough. Ever since they were "stuck in" I have threatened I would do what I now am doing, and I hope it will be to the benefit of others, as I shall try to make it to my own benefit. I know the *experience* will be.

You shall see what all this is about. I do not know whether it is a common practice, but I know it is in many celebrated old gardening books, and perhaps it travels, with very few clerical or other errors, through all the new ones, to "dah" the roots of plants and trees intended for planting out; it is done to forest trees by making a painful of mud and dipping the roots into it. I believe also, if my memory does not deceive me, that it is recommended for small plants,—cauliflowers, broccoli, &c., to be treated so. But there is another way, perhaps no less injurious, *perhaps* a great deal more so; this is it: dibble the holes where the plants are to go, and then fill them with water; as soon as possible after this, plant your plants;—bury them it ought to be, or throw them on the rubbish heap, I do not know which is best; but this I know, that they are both better than planting them and then seeing them get bluer and bluer for weeks, while the man looks at them and mysteriously observes, that "they plants don't seem to take very quick." Or, as a friend once related, that he wanted a good holly hedge, he bought 300 plants, sent a tilted waggon for them, and forthwith planted them; they all died, and "I was very careful to have the roots well puddled too," but the dry weather came, and off went the plants.

Now let us see in what the process of making puddle and making *bricks* differs. The stuff is, generally speaking, much alike in each. I know that stiffish land, a little softened with dressings of lime and ashes, resembles Notting Hill and Westbourne brick-stuff to a nicety. Now, to make bricks, this is ground up in tubs with a little water, then moulded and dried; to kill plants, it is ground up in tubs with a little more water, well squeezed about the plants with treading or by the dibber, as it happens, and, if dry weather follows, it is dried. The plants are thus securely encased about their roots in a matrix of hard dry mud, and the only remaining process is for it to be there for about forty thousand years, when it may be taken up again, cut in two, polished, and placed in a glass case in some future museum, as a rare and curious fossil.

The process of embedding the roots of plants in mud is alike beneficial to the nurseryman, as it is disappointing to the amateur as long as he continues it. The mode is not particular. You want your geraniums to grow strong; you have some good rich stuff, but just before you do the

potting it happens to get well soaked in a heavy rain; you proceed to work, it don't go kindly, it is dirty, but you console yourself by washing them down well with the rose on the water-can, and then they look clean; yes, they are all right now. By and by, the ball will shrink and separate from the sides of the pot, and all the water will go through them as fast as you have a mind to pour it in, but none will get to them; they will soon turn a dark green, and finally, the roots being dead, the top will die also. Give a season ticket of admission to a few worms, and they will produce the same result by the same mode. By the way, I wonder, Mr. Editor, that you did not give this puddling process amongst the most successful modes of killing plants, in an article which you had on this subject some time ago. So likewise are those "thorough soakings" which some are so fond of administering equally injurious, every part excessively well wetted soon turning hard, if dry weather comes on. So, then, in stiff lands mind and keep the roots as free from wetness as possible—that is, from the liability to get boggy; and, above all things, never plant in that sort of stuff; rather plant in dust-dry ground, and water afterwards, than plant in that and leave them so.

I am going to have a row of cabbage planted in the puddle fashion, and another in the proper way, watering a little after planting, and then keeping the land well stirred to avoid any crusting. I know this will be the only mode of curing the propensity in the erring soul.

There is a practice also of docking plants. I have seen celery and leeks served so, and the result was the same. Instead of putting jolly celery plants nine inches or a foot high, with balls as big as your two fists, white with roots, they were cut down to about six inches, and the roots cut back to a little earthless bunch of fibres, not bigger than a smallish painting tool; then soaked with water, and the job was done. The leeks are served the same, only often they are dropped into deep dibbled holes, and then the water is washed in with the pot. Of course, what with the disablement of the plant, and the suffocation which it gets by the puddling process, it can scarcely recover, much less grow.

There, now, I think that will do. I do not feel as if I had been writing a mere theory or fancy, which we can do as well to believe as not, and which cannot affect the practice; but I think and feel that whoever gives the subject due attention will see it as I do.

A. DAWSON.

Calendar.

WORK FOR WEEK COMMENCING JUNE 1.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—Stake runner beans on the north side of the rows, unless they run north and south, which is the best, in which case stake them on the west side, and boe up. Sow lettuce; tie a few at a time for immediate use. Sow parsley, endive, and turnips. Plant out celery, and water abundantly; if convenient, shade the trenches for a week after planting.

TOMATOES will bear more abundantly, and occasion less trouble, if constantly stopped before the fruit. Give them plenty of water, and mulch the surface with rotten dung.

TURNIPS.—Any sowings made now should be managed so as to outwit the fly if possible. Divide the seed into two portions; steep one-half in a solution of sulphate of ammonia, half an ounce to the gallon. Let it steep six hours, then mix with the dry seed, and sow altogether. The steeped seed will come up first, and grow so fast as probably to escape the fly; but if lost there will be a good chance of the other seed following immediately after the first shower, and there will be two chances of a crop. As the fly only attacks the plant in the seed-leaf, it is not so formidable an enemy as it is sometimes represented.

LETTUCES.—Sow two or three different sorts, and let Dixon's Champion Cos be one of them. Plant out on heavily-manured ground. Some should also be sown where they are to stand.

ASPARAGUS to be cut no more after this week; the beds then to be lightly forked over, and covered with a thin coating of rotten dung.

WINTER GREENS to be planted out in showery weather at every opportunity. If only one row can be got out at a time, it is a benefit to the seed-bed in giving the seedlings more room, and a benefit to the plants in preventing their getting drawn.

Flower Garden.

BALSAMS should never be allowed to get pot-bound; it throws them into bloom prematurely, and stops all growth. Therefore, as fast as they fill their pots with roots, shift on in rich light soil. Small plants showing bloom-buds should be disbudded, and shifted to pots two sizes larger. Never let them suffer for want of water. Keep well aired, and in a good greenhouse temperature.

BEDDERS to have as little water as possible, as it tends to prevent them rooting deep. Hoe over the beds between the plants, and pay scrupulous attention to pinching and pegging as required, as on this will depend the beauty of the display as the plants come into full bloom. In pegging, secure first a supply of shoots to the north side of all the trailing plants, as they will grow all the season more freely on the south side.

BULBS are frequently lost through inattention at this time of the year. As the leaves decay, all those that are usually taken up should be lifted and laid aside in a shady dry place, with earth over them, to ripen. They should then be cleared and stowed away, all named kinds with their tallies, so that at the next planting there need be no mixing of colours, or regrets for the loss of choice kinds through leaving them in the ground to be chopped up in some digging operation.

HERBACEOUS PLANTS out of flower may now be propagated from cuttings. These should be put in a cold frame, in a mixture of sand and loam, and kept shaded. It is important to secure plenty of such things as *Alyssum saxatile*, double Wallflowers, *Iberis corifolia* and *sempervirens*, *Aubrietia purpurea*, *Dielytra spectabilis*, &c.

POMPONE CHRYSANTHEMUMS intended for beds and clumps may be planted out in a piece of well-manured ground in the reserve garden, and the only further trouble they will occasion will be to stop every three weeks till the middle of July. When grown in quantities to make a display after the summer hedges are removed, this is the easiest way of all, as they can be lifted in October without losing a leaf by the operation.

ROSES require now to have an engine played upon them as upon a house on fire. This will drive the fly away much more effectually than any other method, and do the roses good too. To fumigate out of doors is a very troublesome affair, and to wash with tobacco-water or solution of albes greatly disfigures the foliage, as the stuff must be strong to be effectual. Gardens newly made may be furnished with roses now as well as at any time of the year. The nurseries supply dwarf plants in small pots at a cheap rate, and these turned out with care, in ground well dug and liberally manured, will grow with vigour, and bloom well in the autumn. In forming a plantation of dwarf roses, we would as soon plant in May or June as at any time of the year.

PLANTING ROSES.—This note may at first seem out of place at this time of year, but in truth it is most seasonable, for this is the best time in the whole year to plant roses out of pots, for if well done they will grow vigorously from the first, and bloom well in the coming autumn. To effect this is not a very difficult task now the large rose nurseries keep such a stock of strong plants for the purpose, many of them potting up *Manettia* and short briars from the nursery quarters during the winter, either for early forcing or to plant out in the spring. These are precisely the same class of plants as are sent out from the open ground, but have the advantage of some sort of protection during severe weather, so that their first growth is not destroyed like that of the ordinary bushes; they can, moreover, be transferred with safety at any time to desired positions, when lifting would be certain death to plants removed from the ground. The chief things required will be a proper attention to the preparation of the beds, and a judicious selection of the varieties to be used. The beds into which roses are transplanted from pots need not, for the first season, be more than eighteen inches deep, and the soil should be rather rich and free than too stiff. There should be a staple of soft fat loam, which should be well intermixed with good manure of any kind and lumps of half-rotted turf; charcoal, charred wood, and clean bones will be a valuable addition. When the plants are turned out of the pots all suckers should be extirpated, the drainage just removed, but otherwise the ball should be disturbed as little as possible, although when the earth has been pressed well to it, a slight pressure near the collar, just to insure the water passing through the fibres, will not be amiss. After a good soaking, the ground round newly-planted roses should be deeply mulched with only half-decayed manure, over which a layer of fine mould ought to be sprinkled, to take off any unsightly appearance among dressed borders, and the plants should be further strengthened now and then by refreshing draughts of liquid manure. These operations, with cleanliness and the watchful eye of an enthusiastic insecticide brought to bear daily upon the welfare of his favourites, will ensure a fine bloom; somewhat later, perhaps than in November-planted rosaries, but in not the less perfection. *Small* plants, especially those sent out in 60's on their own roots, must not be expected to bloom this season, but they will grow finely preparatory to a good bloom next year. The following is a selection of varieties, limited it may be, but unsurpassed in their styles, and in their several adaptabilities for the generality of soils and localities, and also remarkable for their strong and healthy growth. Beginning with the darkest, they may be taken in the following order:—*Hybrid Perpetual*: Vicomte Vigier, Prince Camille de Rohan, Charles Lefebvre, Madame Victor Verdier, Sénateur Vaisse, Le Rhône, General Jacqueminot, Jules Margottin, Victor Verdier, Madame Clémence Joigneaux, C. Guillot, John Hopper, Madame Domage, Baron Gonella, Centifolia Rosea, Duchesse de Morny, Baronne Prevost, Chahriland, Mrs. Rivers, Lord Nelson, Madame Alfred Rougemont, Thérèse Appert, Louise Darzins. *Teas*: Gloire de Dijon and Devoniensis. *Bourbon*: Malmaison, Acidalie, Sir Joseph Paxton. *China*: Mrs. Bosanquet, Cramoisie Supérieure, Archduke Charles.

LAYERING CARNATIONS.—The time is near at hand when the cultivator must take measures for the perpetuation and increase of his stock. The simplest and safest method of all is by layering. Strip off the leaves to the third or fourth joint from the top. The soil in the pots should be stirred, and fresh added to the depth of about two inches. Take a shoot in your left hand, bend it towards the stem of the parent plant with your forefinger, make the incision about half an inch below the third joint, extending it upwards, then cut half-way through the joint, severing the tongue from the shoot. The layer must be gently lowered into the soil, and retained in its proper position by a peg cut out of the common brake fern and dried. Too much earth must not be placed upon the layer, and the more upright the layer itself is the better. In layering, water should be given the day before, and also through a fine rose after shading carefully. The best time to perform the operation is from the middle of July until the middle of August. In about six or eight weeks the layers will be ready to take off; the peg should be drawn out, the layer detached with a sharp knife, and lifted with a flat piece of wood about an inch wide, cut rather thin at the point. The portion of the stem beyond where it is rooted must be removed, and then they must be planted in pairs (two in a pot) in 48 or 54 sized pots. Be careful not to pot them too deep, and do not use a rich soil, but let it be of a light nature. After potting, water them, and let them be placed in a frame on bricks, so as to admit air underneath, and the pots placed upon a good layer of ashes. They should be kept close for a week or ten days, and be fumigated once to destroy green-fly. The lights should then be propped about six inches above the frame, and lowered to about one inch in case of frost, with a mat thrown over, taking care to uncover when it disappears, and in fine weather the lights may be thrown off altogether. During the months of January and February the plants must be kept as free from damp as possible; all decayed leaves must be picked off, and the surface of the soil stirred. Should the weather prove frosty I generally cover the frame over with a mat, and as long as frost lasts I give water very moderately.

CARNATIONS AND PICOTEES.—SAVING SEED.—As these are now coming into bloom, perhaps a word or two may be advantageously said with regard to saving of seed. Few plants are more shy of bearing seed than the carnation and picotee; it often happens that out of a hundred blooming plants you may not get a score pods of seed. It may be accounted for in this way—first, because the flowers do not appear till late in the summer, and hence have not time always to ripen their seed, especially if it be a wet season; secondly, because the flowers that are usually cultivated are so very double as to preclude in a great measure the possibility of much seed being produced. The semi-double flowers yield the most. If you perceive the seed-vessels swell and grow hard, so as to give hope of seed, which it will not do till the flower is fading, then pluck the petals one by one out of the calyx or cup, taking care not to injure the styles (which have the appearance of a pair of horns), for if you do you lose all chance of seed. By

letting the flower-loaves remain in the cup, they are apt to hold the dew and rain, which frequently occasions the whole to rot. As the seed-vessel fills up you may with a pair of scissors cut off the ends of the cup all round, and make a slight incision down it to keep the wet from resting in it. It will ripen towards the end of September, but do not gather it till it is fully ripe, when it will be of a dark brown or black colour.

Fruit Garden and Orchard House.

MELONS need no shade if the hillocks are of good sound turfy loam, and the plants have water when shut up at night. We never knew scorching to happen except through mismanagement. The general causes of ill-health are watering with cold hard water, planting in rich light soil, or keeping them too dry while growing. To ripen the fruit, dryness is essential, but while the plants are growing they require plenty of water, warmed by being put in the house every morning for use in the evening; and the soil to fill in with as the hillocks are occupied with roots should be tough turfy loam; even clay is preferable to the mixtures containing leaf and manure.

Greenhouse and Conservatory.

GREENHOUSE AND CONSERVATORY PLANTS require special attention now. Turn out for the summer those that require to be in the open air for the completion of their growth and the ripening of their wood. A great many of these are suitable for decorating banks and odd places about garden seats, or for groups on the terrace, which is a more profitable mode of disposing of them than hiding them away among the sheds and outhouses. Take care in all cases to guard against worms finding entrance to the pots, and top-dress at once any that require it.

HERBACEOUS CALCEOLARIAS are now in fine perfection, and we have reason to congratulate the breeders of improved forms on the robust habit and beautiful colours that have been produced. Any choice varieties to be seeded should be secured in duplicate, to keep up the varieties from cuttings, as the plants that furnish seed will probably die. Those to be cut from not to be allowed to ripen a single seed; cut away the flower-stems as soon as the bloom is nearly over, and put them in a pit facing north, with the lights off night and day, and the sun kept off by a thick screen of mats. When watering, drench these mats, the evaporation from which will assist the plants to break; and secure cuttings as soon as they are large enough to be taken off.

CHELOSIA AUREA PYRAMIDALIS is now showing flower, and will be benefited with weak liquid manure occasionally. It is one of the most useful of all the novelties for conservatory decoration, and needs the same treatment as Cockscombs. Plants required extra fine to have a shift in rich light soil.

CINERARIAS are generally very mixed as to quality, owing to the too frequent keeping of seedlings that have pleased by their colour, but had no other good quality. Seeing how many really beautiful varieties are now obtainable, it is a positive waste of time and glass-room to propagate any seedlings that have not some decidedly good qualities. We name this now, because many gardeners who grow these plants largely for decoration are at this time of year tempted to propagate from whatever old plants they possess, with too little regard for their quality, whereas if a few of the best new ones or a complete set have to be purchased, the cost is little, and quality is of the first importance in a flower which every one can criticise. When admiring a sheet of Bourgainvillea, none of us think about properties; but the most uninformed take note of the form and proportions and colouring of a Cineraria, and every second-rate seedling should be thrown on the muck-heap as soon as the bloom is over, so as to reduce the work of propagating to a few of the very best. Those to be kept should either be moulded up in the pots or be planted out on a shady border in rich sandy soil, an inch below the level, to induce them to break freely for increase of the stock.

PROPAGATION OF EXOTIC HEATHS.—As the season has arrived when heaths are usually propagated in quantities, a few practical remarks may be useful to some of our readers. Heaths may be propagated with certainty, but the process consumes much time; hence we advise those who wish to make the best of their time to purchase their stock, as the propagation of the heath is a somewhat slow process. There are those, however, whose principal gratification lies in the accomplishment of the most intricate and patience-testing part of the craft, and to such untiring enthusiasts we owe our thanks for very many of the beautiful hybrid varieties we possess. Raising from seed is interesting on account of the varieties it produces, and if two varieties are properly crossed by impregnation, something differing from the parents will be obtained. In order effectually to accomplish this, some experience by practice must be attained, as the anthers must be extracted, by means of tweezers, from the flower that is to bear the seed, whilst the stigma must be guarded from injury, and have the pollen from some other variety applied to it. When the seeds are ripe and thoroughly dry, they may be sown at once in pots of finely-sifted peat, pressed tightly into the pot, and well watered before sowing, afterwards covered with a bell-glass; they may then be placed in any cool house or pit, where they can be kept in an equable state of moisture. To this end, place them in a shady corner until they vegetate, when they must be placed quite close up to the glass until they are large enough to handle; they must then be potted singly in very small pots, known as thumbs. There is some nicety required in handling these, and indeed all the heath tribe, for their extremely delicate roots will neither allow of exposure to the atmosphere nor bear other rough treatment; consequently all things must be in readiness to do the work quickly. Whilst plants are small, be they seedlings or cuttings, they must not be overpotted, or the mass of soil will become sour before their roots reach the pots; therefore the smallest pots and finest peat soil, with a larger proportion of silver-sand in it than for larger plants, must be in readiness. When potted, the pots being so small, would, if not protected from the action of the air upon their surface, soon get injuriously dry; have, then, a shelf, or tray with edges, standing up so as to hold sufficient clean sand to plunge them up to the rim. The above directions apply as well to young plants from cuttings as from seed. As to cuttings, before preparing them, have in readiness the pots and bell-glasses to fit them. Having prepared the drainage, which should fill one-third of the depth of the pot, the coarser crocks being placed at the bottom and the finer upwards, and carefully packed so as to keep the soil from entering amongst them, fill to within a quarter of an inch of the top with fine sandy peat, very tightly pressed in, and the remaining quarter of an inch

with silver-sand. The pots, when so filled, may be placed in a pan of water until thoroughly wetted through, then gently lifted out to drain for a few minutes whilst the cuttings are being prepared; they will thus be watered without disarrangement of the soil. Take the cuttings when the wood is a little more than half ripe, or when they begin to turn brown; and as this will take place in different varieties at different seasons, according to their period of growth, so must the cuttings be put in at different seasons; but as the heath is seldom quite dormant, suitable cuttings may be got from the greater part of them during the months from June to September, which time is best, as they then form a callosity before winter, and will start into growth the following spring. When preparing the cuttings, the greatest care is required in taking off the leaves from the part of the cutting which goes in the soil not to injure the bark, also in preparing the base of the cutting with a clean cut; and this may be most effectually done across the thumb-nail, as in nibbing a pen. From one to two inches is sufficient length for the cuttings, and they need not be inserted more than half an inch in the soil; prick them in with a fine pricker, and carefully close the sand against each. When the pot is filled with them, dip it again in water, so that it just run over the rim without wetting the foliage of the cuttings, and cover with a bell-glass, which must be taken off occasionally to be wiped, and should damping take place among them take care to dry them. When starting an inch or two into growth, they must be turned out of the pot, and carefully separated and potted. The after treatment is given above.

TREATMENT OF YOUNG ERICAS.—In choosing young stock from the nursery, do not aim at size so much as healthy plants in vigorous growth, short in the leg, well furnished with branches, and by no means pot-bound. Be not lured by plants in flower, as flower is often the result of cramped roots; and when once the heath gets cramped and pot-bound it is difficult to make a fine specimen of it. If received in spring or summer, and they seem to require a shift, which may be known by carefully turning them out of the pot upon the hand, to see if the roots form a network over the ball; if so, they will take a shift into pots a size or two larger. Make ready pots of the size required, and if new, soak in water before using, otherwise they will exhaust the soil of its moisture; also provide crocks of different sizes, and peat earth not too finely broken, amongst which, if it is thought to require it, sift a little silver-sand, some lumps of charcoal as big as filberts, to throw into the pot a few at a time as the potting goes on; these act as sweeteners of the soil, and help the circulation of water through the mass. A good drainage is of the first importance. Having secured this, press into the pot a little lumpy peat to set the ball on, and so regulate it that the top of the old ball may come within about half an inch of the top of the pot. Fill in round the sides of the ball with the new soil, and ram it tightly in with a blunt stick, so that the water, when given on the surface, may not run away through the new soil without wetting the ball. At this stage the form of the plant should be attended to, the branches pegged out, and taught to take such a direction as will ultimately form a symmetrical specimen, without the aid of so many stakes as are generally used. They may then be placed in a frame or pit, upon a hard bottom, where no worms can get into the pots, for if this happens they will fill up the drainage, and cause much trouble if not injury to the plants. In such a place, during the summer months their growth will be rapid, as their roots stand cool; and although plenty of air must be given, and warm showers allowed to fall upon them, yet a diminution of air may take place at three or four o'clock, p.m., so as to shut up for a few hours during the evening a large amount of solar heat, when more air may again be given. In autumn they must be removed to the house, and if young stock are received from the nursery in autumn they must have all faded blossoms picked off, and be placed in the heath-house until the following spring, when they may be treated as already described. As soon as blossoms fade they should always be cleared off the plants; from slow-growing kinds they should be picked off, but the free-growing kinds may be cut off, taking with them the points of the shoots. This will keep the plants compact, and, as they attain to the size of specimens, potting will be required less frequently, as they will stand and flower for years in the same pot, with a little fresh surface dressing occasionally; but when potting is necessary it may be done when the pruning takes place, and if the plants can be put in a pit for a few weeks, and treated to a little solar warmth, it will assist the new growth. A puff of sulphur must occasionally be given amongst them to keep off mildew, and the greatest care taken that the roots are at all times kept in a healthy state of moisture, and this by the use of soft water alone; no hard pump water or liquid-manure must be given to the heath. Some cultivators know by the weight of the pot if the soil be in a proper state of moisture; others use, perhaps, a better method, and one which may be soon acquired, viz., that of tapping the pot with the knuckles, and listening to the sound. Any one can easily learn this, by taking two pots, one of which is known to be wet, the other dry, and practising upon them, observing at the same time the difference of sound. A shade of tiffany thrown over the heath-house or pit in bright weather will tend to preserve the foliage green and to promote their growth, but heavy shading should be avoided. In turning out into the open air in summer, turn out only the hardiest varieties for about six weeks during July and August, and house again before the heavy rains set in, otherwise they may saturate the soil and injure the roots. Also be careful to place them upon racks or concrete, so that no worms enter the pots; and choose a place for them shaded from the meridian sun, but exposed to its morning and evening rays.

Stove and Orchid House.

STOVE CLIMBERS require much attention now. A moderate freedom of growth must be allowed, but shoots that interlace are sure to be weakened, so generally an occasional thinning, regulating, and stopping are needful now.

Forcing Pit.

PINES must have atmospheric moisture. Shut up early and syringe, and water the floor of the house early every morning. Give a little air at night about two hours after shutting up to water. Use as little shade as possible to fruiting plants. The temperature may go up to 95° for a maximum.

* * * SUBSCRIBERS requiring back Numbers or Parts of the GARDENER'S MAGAZINE to complete sets, are requested to order them through their bookseller, who can always procure them from the London publisher. At the same time, instructions should be given that in case some of the numbers required are out of print, as many as can be had should be sent, it being a rule with the book collectors, if they cannot obtain ALL the numbers wanted not to take any, saying they are "out of print."

A SUMMER MORNING'S SONG.

FROM THE DUTCH OF J. TOLLENS.

Up, sleeper! dreamer, up! for now
 There's gold upon the mountain's brow—
 There's light on forests, lakes, and meadows;
 The dew-drops shine on flow'rot bells,
 The village clock of morning tells.
 Up, men! out, cattle! for the dells
 And dingles teem with shadows.

Up! out! o'er furrow and o'er field;
 The claims of toilsome moments yield
 For morning's bliss, and time is fleet
 Than thought—so out! 'tis dawning yet.
 Why twilight's lovely hour forget?
 For sweet though be the workman's sweat,
 The wand'rer's sweat is sweeter.

Up! to the fields! through shine and stour;
 What hath the dull and drowsy hour
 So blest as this? the glad heart leaping
 To bear morn's early song sublime;
 See earth rejoicing in its prime:
 The summer is the waking time,
 The winter, time for sleeping.

Oh, fool! to sleep such hours away,
 While blushing nature wakes to day,
 On down through summer mornings snoring.
 'Tis meet for thee, the winter long,
 When snow falls fast, and winds blow strong,
 To waste the night amidst the throng,
 Their vinous poisons pouring.

The very beast that crops the flower
 Hath welcome for the dawning hour.
 Aurora smiles! her beck'nings claim thee;
 Listen—look round—the chirp, the hum,
 Song, low, and bleat—there's nothing dumb—
 All love, all life. Come, slumb'rer, come!
 The meanest thing shall shame thee.

We come—we come—we wand'rings take
 Through dewy field, by misty lake,
 And rugged paths, and woods pervaded
 By branches o'er, by flowers beneath,
 Making earth odorous with their breath;
 Or through the shadeless gold gorge heath,
 Or 'neath the poplars shaded.

Were we of feather, or of fin,
 How blest to dash the river in,
 Thread the rock-stream as it advances;
 Or, better, like the birds above,
 Rise to the greenest of the grove,
 And sink the matin song of love
 Amidst the highest branches.

Oh, thus to revel, thus to range,
 I'll yield the counter, bank, or change;
 The bus'ness crowds, all peace destroying;
 The toil, with snow that roofs our brains;
 The seeds of care, which harvest pains;
 The wealth, for more which strives and strains,
 Still less and less enjoying!

Oh, happy, who the city's noise
 Can quit for nature's quiet joys,
 Quit worldly sin and worldly sorrow;
 No more midst prison-walls abide,
 But in God's temple, vast and wide,
 Pour praises every eventide,
 Ask mercies ev'ry morrow!

Come!—though a glance it may be—come!
 Enjoy, improve, and hurry home;
 For life's strong urgencies must bind us.
 Yet mourn not; morn shall wake anew,
 And we shall wake to bless it too—
 Homewards! the herds shall shake the dew
 We'll leave in peace behind us.

CAMELLIA CULTURE.—No. IV.

If the cultivator has carried out the instructions previously given, his plants will be occupying now an airy cool position in some glass structure where the force of the sun's rays does not come directly upon them. But it is not in every case that a suitable house, to be devoted entirely to them, can be secured, though even with cultivators so situated much can be done to make the house agreeable for them by judicious shading, and a free circulation of air through the portion of the structure they occupy. With a view to meet the wants of my readers, I have endeavoured that these papers should appear from time to time, containing such portions of the details of Camellia culture as will be applicable to the circumstances of the majority of cultivators when they come to hand; and in this paper, as I promised at the conclusion of my last, the details of the summer treatment required will be given.

As to the proper treatment of Camellias during the height of our English summer, I think there can be but one opinion, that, taking our seasons as a whole, they are not adapted for the out-door cultivation of Camellias. Such, however, has been my experience in the more southern counties; but this remark is only intended to apply to collections, and not to individual varieties, which I have

myself seen enduring an ordinary winter in the open border on the south coast. Therefore I think those who have only a moderate convenience will do well not to risk a valuable collection of plants to the uncertainty of this climate by exposing them in the open air, subjected, perhaps, to a few weeks' sultry summer weather in the early part of the season, only to be visited by drenching rains and cold nights through the month of August. These are my reasons why I would not advise the placing out in the open air valuable plants, on which we depend so much for winter and early spring flowers.

In places where it is not possible to keep them under glass throughout the year, the best position for them out of doors is under the shade of a north wall or fence (the shade of trees I dislike, on account of the drip). When such a position must be resorted to, the cultivator should be particular to observe that they should have thoroughly completed their growth before they are taken out, and it would be better still if their flower-buds are prominent and plump, and then they will have nothing to do but to quietly go to rest, during which time the previously-formed buds will swell and mature themselves much better than while the plants are in a state of activity. At the end of the first week in June is quite soon enough to expose them out of doors, but the later-flowering plants will not do to be put out thus early, as they will not have hardened their growth.

In the absence of a proper Camellia house, the earliest vinery may sometimes be brought into use for Camellias after the fruit is cut, as they delight in the shade of the vines, and the abundance of air given to vineries when the fruit has been cut will just suit them, and an occasional syringing of the Camellias will do no harm to the vines. In such a structure they would be much less trouble to the gardener than when exposed in the open air, and very much better for the plants, as they are sheltered from storms and wind, and the moisture at the roots (one of the greatest secrets in Camellia culture) will be under the control of the operator instead of being at the mercy of the elements. Peach-houses generally are not adapted for them after they have completed their growth, as they are too much shaded and confined. But many times one end or a portion of a span-roofed plant-house can be made to suit them admirably, by shading the roof, and by standing the plants on a cool bottom, and by allowing a free circulation of air night and day until the end of September.

The success of those old-fashioned dark houses which I have advocated in previous articles on this subject for Camellia culture is abundantly testified by the one at Knowle Park, briefly alluded to by me in my notes from that place; for there they can be seen in a span-roofed house one hundred feet long, in the finest possible health and vigour, producing flowers in abundance. Why it is that those who professedly admire them cannot see the utility of providing a suitable structure is past my comprehension, for they are evidently a class of plants that have many claims upon our notice; for they are not only desirable and useful winter and spring flowers, but when planted out in the borders, as they are at Knowle, they give to any well-ordered garden a character of stateliness and grandeur that is not secured by any other class of plants; and considering that they are much sought for as desirable acquisitions to the lady's toilette, we may well complain of the make-shift system under which they are ordinarily grown.

That some good collections are grown without the aid of a house devoted entirely to them I am not prepared to deny; but I would ask the cultivator of such collections what amount of labour they entail, from the fact that they are constantly removed from one house to another, to secure the proper degree of temperature they require to suit the different stages of their growth; and, even if he be an enthusiast, he will be obliged to admit that it is very great in comparison to what it would be if grown in a house by themselves.

The more practical details of their management during summer may be summed up in a brief space. One of the most important is to carry out a thorough system of watering, which, when the plants are under glass, is no difficult matter; but with the man whose plants are without shelter it is not so easy to work out. The more favoured cultivator should keep his plants liberally watered with water of the same temperature as the house until they have completed their growth and formed their flower-buds, after which it should be gradually reduced, only to give sufficient to the whole ball of earth to keep it moistened without saturating it. Where plants are exposed, the cultivator must endeavour to work out the same rule, but there will be times and days when plants exposed will require double the quantity they will at other times. When a force of circumstances compels us to expose our plants to a certain amount of rough usage, it becomes the gardener to reduce the ill effects of such treatment by devising such means as are within his reach, and are admissible under the circumstances; and in the case of Camellias exposed in summer, much may be done by plunging the pots in cocoa-nut fibre or any similar material, and by securing them against the force of the wind, and by standing the plants on

some firm bottom, so that the worms cannot get into the pots and choke up the drainage. These are essential details, that will be observed by those who wish to excel in the cultivation of these noble plants.

I shall conclude this paper with the remark that those plants intended for autumn or early winter bloom should receive particular attention in watering, as an excess or an insufficiency may cause many of the bloom-buds to fall; and should there be more buds formed than the plant ought to carry, pick them off a few at a time at intervals of a week, that the plants may not suffer from any sudden loss.

J. C. CLARKE.

Correspondence.

GROWTH OF VEGETABLES IN PRIVATE GARDENS.

In your issue of May 11, you have a leader on the early supply of vegetables to Covent Garden Market, in which is set forth the notion that private gardens where gardeners are kept do not and cannot compete with the market gardeners around London. That no private garden can compete with Covent Garden in the earliness and quality of the supply of vegetables is indisputable and certain; for not only the market gardeners around London cater for its supply, but all the world, not excepting hundreds of private gardens in England where gardeners are kept.

If your leader was in any way intended as an apology for the shortcomings of well-managed private gardens, it is altogether delusive in its aim, and calculated to produce the very dissatisfaction it was intended to remove, and requires, on this account, an apology from you; for the generality of employers know that there is no stint or spare of the means you advise for the production of the earliest and best quality of vegetables.

The writer of this has had many years' experience as gentleman's gardener in town and country, and is now in business as a market gardener in a town where the earliest and best produce is in demand, and he is keenly alive as to the means, time, and price of garden produce. As to the merits and advantages of market gardeners over gardeners of private gentlemen, it must be obvious that the former have advantages over the latter, but not from the causes you state, but from his attempting to grow only such things as the nature of the soil and situation render almost certain, avoiding such as he knows will not succeed, so that great breadths in most favourable conditions of growth afford better opportunities for picking the first and best from the best conditions of cultivation; whereas the gardener of a private gentleman is expected to have everything in season; and if one of the everything fail, it is an object of mark and den. erit in the gardener. Your remarks on the means and for encouragement of early garden produce are very good; but they have nothing to do with the supply of early vegetables in Covent Garden.

The first vegetables of every kind in Covent Garden come from France. Every steamer that crosses from Boulogne to Folkestone brings vast quantities; they go to London by truck-loads every day; they are not detained to go by goods train, but go by the earliest after arrival, and from London to all parts of England. French vegetables are sent to London till the English supply becomes general, and then they are valueless. Do not suppose that this French supply is an insignificant item in the English market, for it is by no means so.

I am not in a position to furnish quantities, but I often look at the huge baskets, and I know that sometimes by one consignment there are lettuces enough to strip acres of land, even if the crop is good. There have been sent seven tons of strawberries in one day to London, *via* Boulogne and Folkestone, before English are in. This season, more than a month ago, before I began to pull radishes, French were selling here at 2s. per hundred bunches. There is in Folkestone a wholesale shop for the supply of French vegetables, and all through the winter salading might be had; and now, with a day's notice, any quantity of peas, new potatoes, carrots, turnips, superior lettuce, cherries, cut flowers, &c., may be had, and in another week splendid cauliflowers, such as are seldom seen in England even in the month of June. These are also in abundance in the London markets. I do not write this with any spirit of disaffection towards free trade, or to detract from the merits or efforts of market gardeners, but to correct the false notion that the earliest supply is English; and that because a thing is to be seen in the greengrocers' shops in London it ought therefore to be had in a private garden where a gardener is kept. All the world caters for Covent Garden, and not the least important part of the supply of the best and earliest is from the private gardens of noblemen and gentlemen in England.

GEORGE PILCHER.

Replies to Queries.

Planting a Fountain.—R. W. P.—Nothing better for the vicinity of a fountain than Pampas grass, *Tritoma nvaria*, hydrangeas, fuchsias, *Lysimachia thyriflora*, *Gnothera Fraseri*, *Calla Ethiopica*, *Osmunda regalis*, *Athyrium filix femina*, *Arunda donax*, and other such plants of graceful habit and fond of moisture. You cannot have anything grand to flower in winter, but you may plant the banks with winter aconite, Christmas rose, and primroses. In a sunny, dry position, one or two laurustinas would be useful for winter bloom.

Hedge for Division.—S. W. B. R.—Cotoneaster makes a nice hedge if trained to a trellis of stakes, or a lattice of hazel-rods, three or four feet high. You could obtain from a nursery plants of sufficient size to make an effect at once, and they can be removed now or any time in autumn or spring. If you begin with small plants, it will take five years to make a good fence. It can be managed with very little trouble. Cuttings put in frames at the end of July will be well rooted by next spring, but they grow slowly. If you are really anxious for this fence, and cannot use large plants, plant them when well-rooted eighteen inches apart in the line where they are to remain, and train to wires as they get up; this will do away with the necessity of a trellis, and may be added to as the growth requires. Strong bushes we should plant three feet apart. Veronicas would make a fine hedge in a warm climate, and for these wires would do as well as stakes; none so good as *V. Andersoni*. This would certainly

answer, but must not be clipped, but cut back moderately with the knife. Lastly, roses are first-rate for divisional lines, especially the robust-growing hybrid perpetuals.

Diseased Vines.—C. P.—Your vines are suffering from defective root action, the cause of disease in nine-tenths of the cases of vine failure submitted to us. You do not say how they are planted, and therefore it is impossible to advise you minutely. They are either in a damp border, or a border excessively fat with undecomposed manure, or where they have not a sufficient amount of sun-heat.

Planting after Tulips.—R. Thomas.—Why grieve that you cannot plant your beds till the middle of June? All you need do is to get the plants shifted into 48-sized pots, and plunged out of doors till wanted. Then you can turn them out without any check, and in full bloom. So in autumn you need not take up your plants till the end of October, and you have then good time to plant the tulips. Suppose you were to have some kind of cheap frame-work for inclosing those beds, and then fill them with potted plants for the summer, on the plunging system. That system proves to be about a hundred times more grand than any system of planting out, and it has but one defect, and that is, that it uses an enormous quantity of plants, but that is an advantage to those who grow plants in quantities. But you have only to give your bedders another fortnight's growing.

Caterpillars and other Pests.—Philip.—There will be no injury by the splashing of soap or chloride-of-lime solution on the soil. If any effect is produced, it will be to the benefit of the plants, but we doubt if you will get rid of caterpillars by any method except hand-picking. The best remedy for red-spider is pure water alone, or the fumes of sulphur. Red-spider never attacks plants that are growing vigorously, and that have plenty of moisture; in fact, moisture is certain death to this pest. Soda will, if strong, spoil the foliage; if weak, not harm the vermin. Stick to plain water or tobacco-water, and you will do well.

Cucumber Failure.—W. M.—The vines that bore so well, and then produced distorted fruit, and got full of fly, were probably exhausted through being in a poor soil, or wanting water. When cucumbers play these pranks it is usually best to destroy them. Touch up the bed and plant again, but you might have cured yours by using good linings to the bed, slightly pruning back the vines, and giving them frequent syringings with soft water over the leaves, and manure-water at the root.

Turf on Dry Slopes.—W. Roberts.—We have seen the hottest slopes of sand and chalk as verdant as a fat meadow a fortnight after the hay was carried. Some grasses will grow on such slopes, such as Sheep's Fescue and Italian Rye. Better than all the grasses are such plants as common camomile, common wild thyme, common yarrow, and white clover.

Classification of Auriculas.—Septimua.—You must never be surprised to find in one list a variety classed as green-edged, and in another list the same variety classed as gray-edged. The fact is, many varieties vary in respect of the colour of the edging, and those that do not vary may by some growers be called green, and by others gray. There is scarcely a gray but has a tinge of green to be found, and the system of classification is at fault, not the critics who differ as to the class to which a particular variety belongs.

Early Tulips.—Simson.—No; we do not approve of the prevailing system of dragging them out of the ground when they are fresh and green, and compelling them to ripen off artificially. We do not approve of any violent proceedings, and are quite satisfied nature will not be outraged with impunity. Bulbs so treated do not flower so well the next season as those allowed to ripen naturally, and that are not taken up till their leaves are dead, or nearly so.

Calceolarias.—R. Whitbread.—We cannot say whether they will die off this summer as they did last, and as they have too frequently done in past years. But we can say this, that in several experiments with calceolarias at Stoke Newington, those planted in soil consisting of about three parts out of four of rotten hotbed dung, none died, and the growth and bloom were the astonishment of many practicals who saw them.

Ivy.—W. W. W.—The common Irish ivy is the best you can use for edging the large compartments in a public garden. Do not employ *Hedera Regneriana* except in some isolated spot apart from the general scheme, as it begins to grow so late in the season that at this time of year it is scarcely presentable. In a warmer climate than yours we might recommend it, but it will not do for the extreme east of England except as a wall shrub; and when warmed by a wall, it is scarcely any later in making its new growth than any other ivy.

Geranium.—C. M., Isle of Wight.—Your seedling, the result of a cross between Helen Lindsay and Lord Palmerston, is a nosegay of the grandest character, the truss of immense size, the flowers bright pink. The nearest to it in the nosegays is *Boule d'Asperides*, which is a lighter colour than yours.

Dahlias.—W. Price.—The following are a good selection: Miss Henshaw, Mrs. Piggott, Charlotte Dorling, Bird of Passage, Helen Potter, Norfolk Hero, Hugh Miller, Charles Turner, Fanny Purobase, Leah, Mrs. Wyndham, Anne Austin, Madge Wildfire, Lord Palmerston, Boh Ridley, Scarlet Gem, Andrew Dodd, Lord Derby, Midnight, James Backhouse, Juno, Lilac Queen, Criticism, Blushing Fifteen, Dursley Gem, Charles Perry, Garibaldi, Regularity, Startler, Artemus Ward, Miss Frampton, Stafford's Gem, Lady Paxton, Norah Creina, Pauline, Prospero, and Fanny Surt.

* * * Several reports are unavoidably kept back, owing to the pressure on our space this week.

FLORAL AND CHORAL.—The other morning *Mr. Punch*, as he chipped his second egg, saw his youngest daughter smiling at this notice in the *Guardian*:—

WANTED, a Situation as HEAD GARDENER. Has great interest in flowers. Lately taken bass part in surpliced choir. Single. Steady. Good reference. Address, &c.

Well, what is there to laugh at, Miss? was *Mr. Punch's* stern remark. There is nothing very ludicrous in the fact that a gardener is able to sing bass. Oh, you are tickled by the surplice, are you? A gardener in a surplice! Well, pray, and why not, Miss? "A saint in serge is twice a saint in lawn," and a bass voice in a surplice may to some ears sound far finer than if its possessor merely wore a fustian jacket. Besides, the surplice shows the gardener is a man of High Church views, and not a dangerous dissenter; and this may serve to recommend him very strongly to some people. There are persons in the world who would hardly eat asparagus, if they knew that it was cut by a go-to-mooting gardener.—*Punch*.

The Gardener's Magazine.

SATURDAY, JUNE 8, 1867.

VICTORIA PARK IS AGAIN IN DANGER of being despoiled, and the inhabitants of the eastern parts of London are crying out for help to resist the invader, and establish inviolate their right to recreation and fresh air on the 290 acres originally allotted them. A year ago it was proposed by certain gas companies to erect new works within a few hundred yards of a portion of the park much frequented by the public; and, after a hard battle with the promoters, they were beaten, and retired. Now the speculative builder is the invader; and it is reported that not less than one-third of the entire area, now covered with grass-turf and trees, is to be appropriated to building purposes, reducing the park to less than 200 acres, though the original 290 afford a space far too contracted for the tens of thousands who need a place of open-air resort for healthful exercise in this part of London. This is a very serious case, and we trust it will meet with the attention it deserves, not alone in the eastern parts of the metropolis, where the park is known and appreciated, but throughout London—yes, and throughout the country; for it is a matter of more than local importance. The preservation of public parks and pleasure grounds generally is in some way related to the preservation of this particular park; and public opinion must now be heard in defence of public rights, for opinion is the only weapon the people possess either for the defence or advancement of their rights and interests.

Victoria Park was opened 1842. As an open space, it was from the first of inestimable value to the over-crowded districts of Mile End, Bethnal Green, Whitechapel, Shoreditch, and Hackney. But, as a park, it has only within some seven, or at the most ten, years past acquired any degree of celebrity for its beauty. The site was never inviting, and it has always been severed into two parts by a public road. Everything in the laying out of this park was done in a careless manner—in a manner which would not have been tolerated at the West End of London. The trees, in irregular plantations, were planted in rows; the walks and roads were made to follow every little irregularity of surface; the ground was sown with grass without being levelled, and the margin of a sheet of water was left with a steep gravelly bank from three to twelve feet high. The trees have saved it. They have grown superbly; they have obliterated harsh lines, and harmonized incongruous elements; they have given an air of richness and repose to a place which was made wild without being made picturesque; they have contributed variety, comfort, and shade to walks that were designed with bad taste, and have made views of their own, irrespective of the levels and configurations of the principal compartments. Under the skilful care and ceaseless watchfulness of Mr. Prestoe, Victoria Park has become celebrated for its beauty. As an arboretum, it is worth preserving intact; as a place for recreation, and as one of the lungs of London, it is worth any sacrifice to keep the builders from encroaching on its precincts. The population that may fairly claim to have a direct interest in the preservation of this park numbers at least one million persons; so we are assured by Messrs. John Holms and John Plummer, who, in behalf of the toiling population of East London, have besought us to aid in checking the progress of spoliation. It would be a calamity for this now beautiful park to be shorn of its fair proportions. Not an acre can be spared; it is actually too small for the purpose to which it is dedicated, and all the open spaces nearest to it are fast being cut up by railways or covered by houses. Moreover, the eastern parts of the metropolis are the least salubrious: there are factories innumerable; there are vast districts inhabited by the poorest classes, where, owing to imperfect drainage and over-crowding, fever is a permanent plague, and cholera a frequent visitant. In a very few years hence Victoria Park will stand alone, the only breezy No. 110, NEW SERIES.—VOL. X.

open space for miles around, the last refuge of the destitute when desirous of a breath of the pure air of heaven, and the music of a bird or a rustling leaf. To cover one acre of this ground will be a crime; and this crime can only be averted by the power of public opinion, which we earnestly hope will be uttered promptly and without equivocation.

It is impossible to have this case brought before us and not feel that the governing classes are over careful of themselves. We believe there is not an Englishman, rich or poor, who grudges the expenditure incurred for the keeping and embellishing of the West-End parks. We confess, speaking for ourselves alone, that we do not; and we hope yet to see the beautiful gardens lately planted by Albert Gate in Hyde Park extended westward, so as to take in another strip of the sheep-walk which abuts upon the Drive there. But it will be supremely indecent if the government permit the abstraction from the poor of the East-end of London of 100 acres of recreation-ground, while the parks in the West of London, and to which the wealthy chiefly resort, are being made more and more magnificent. It is on this ground, that public expenditure should be regulated by just principles, that we implore the earnest co-operation of all classes to put such pressure upon the government as shall secure the preservation of Victoria Park; for one third part of the whole population of London look to it as their only place of free resort for healthful exercise and innocent recreation. There should be meetings called in all parts of London, and petitions and protests should be poured in upon the government while an hour remains to avert the contemplated mischief. Let Manchester, Liverpool, Birmingham—all the great towns—help in the same direction, remembering that if public parks of which the London poor are almost the sole possessors, can be turned into building ground at the whim of a commission, all the great manufacturing towns in the country may be robbed of their breathing grounds, and the poor be everywhere excluded from the occasional enjoyment of the sight of a green tree, except by climbing the wall of a private garden, or rusticing in the midst of intoxicating drinks. Messrs. Holms and Plummer say in their appeal, "Fancy that portion of St. James's Park abutting on Piccadilly being covered with houses! This is what is being done at Victoria Park." If the people are resolute they can defend themselves, and if they are not the park must go; for the governing classes of this country are strangers alike to the justice and generosity needed to bring about a sufficient opposition to stay the wrong that it is intended to perpetrate in the East End of London.

THE LINDLEY LIBRARY.—In another column will be found copies of correspondence on the subject of the appropriation of the surplus funds of the International Horticultural Exhibition of 1866, in which it is proposed on the part of the Executive to establish a library under the foregoing designation, the nucleus to be the late Dr. Lindley's own library, which the Royal Horticultural Society has already provisionally secured. It will be seen that the Council of the Royal Horticultural Society accept the proposal in its entirety, with the slight exception of suggesting an amendment of the 5th clause. At a meeting of the Executive Committee of the International Exhibition, held on Monday last, the proposals were confirmed, inclusive of the amendment suggested in clause 5. We may therefore consider the "Lindley Library" as a *fait accompli*.

WORCESTER FLOWER-SHOW.—This kind of exhibition has long been in abeyance in Worcester (says the *Worcester Herald*), owing to a variety of causes, jealousies, indifference, &c., into which we need not enter. An effort, however, is at length about to be made for the re-establishment of flower-shows. A short time ago several promoters of the cause issued a circular, setting forth their desire, and several subscriptions were promised, including £5 from the Earl of Dudley. Mr. H. Gummery, of St. John's, was elected hon. sec., and called a public meeting at the Guildhall a fortnight since. The chair was occupied by the Mayor (John Stallard, Esq.); also present Messrs. W. Webb (Sheriff), E. Webb, Josiah Stallard, J. Wood, Redgrave, Birley, Evans, Close, Bozward, and J. W. Williams. The Mayor, in opening the proceedings, said that the objects of the meeting were to decide if it was desirable to hold a flower-show in this city during the present year, and if so to appoint a committee to make the necessary arrangements. He had found that this city was greatly behind other places in this respect, as in almost every small town and country village the great event of the year was the flower-show, but for some reason or other they had not had one in this city for the last three or four years. Those which had been held previously had not prospered very well in a financial point of view, but still he could see no reason why that should be the case, and they must manage to be more careful in the matter of expense. On the last occasion they had gone to a great expense in engaging the band of the Coldstream Guards, but now they had plenty of local talent. Mr. Redgrave said that the expense of bringing the Coldstream Guards' band here was £100. A short conversation ensued, in the course of which Mr. Bozward agreed with the effort being made, but

suggested that a cottagers' show should be combined with the general exhibition. Mr. Redgrave said that had always been done, but Mr. Bozward wished the cottagers' show to be made a special feature. A committee consisting of the gentlemen attending the meeting was appointed; and on the place for holding the show being mooted, Mr. Williams suggested the Market House, which the committee entirely approved of. A sub-committee was then appointed for making the necessary arrangements, to collect subscriptions, and to call a general committee meeting when requisite. Mr. Gummery was unanimously appointed hon. sec. It is intended that the first show shall be held in July, and another in September.

THE MANCHESTER EXHIBITION, which was opened yesterday in the Manchester Botanic Garden, is one of the most extensive and magnificent ever held in the northern parts. Southern growers have contributed liberally, indeed, there are but few names amongst celebrated exhibitors wanting; but the local support accorded is even more satisfactory, we think, than all the assistance rendered from distant gardens. Manchester is a smoky city and has a bad climate, yet the contributions from the immediate neighbourhood are both numerous and meritorious in the highest degree. The Magazine is printing while we insert these few words to chronicle a good beginning; in our next we shall hope to present a report. It is expected that on Monday next many thousands of visitors will arrive from the great manufacturing and trading towns round about, and even from Sheffield, Leeds, and Birmingham. We can assure our friends of the midland and northern districts that an hour or two of travel will be but a small effort as compared with the magnificent spectacle and the abundant interest of this exhibition.

ANOTHER HYDROPULT!—We have been asked to try the "Niagara" (Holman's patent), manufactured by Tangey and Holman, of Birmingham, and 10, Laurence Pountney Lane, London, and it has been fairly tested and taken to pieces. It is not made of "brown paper," as an instrument of this class was once described to be in these pages; nor is it a "foot refrigerator," to use another term applied to a hydrocuilt that wetted the operator's feet as much as the plants for which the water was solely intended. This is at once a substantial and a skilfully constructed engine, demanding no extravagant exertion, and performing its work admirably. It has one piston-rod only, and the possibility of going out of gear by any lateral pressure of the hand is reduced to a minimum; but there are two cylinders, one for drawing, the other for delivery; and an air vessel extending the whole length of the machine contributes in a material degree to render its action easy and constant. It has a solid foot, two lengths of hose, and a jet fitted with a spreader, so that a stream or a fine shower may be produced at the pleasure of the operator. We strongly recommend the "Niagara" force-pump as one of the best and cheapest portable engines adapted for garden use we have hitherto seen.

FINCHLEY, FRIERN BARNET, AND HORNSEY HORTICULTURAL SOCIETY.—A special meeting of the committee was held at The Compasses, Hornsey, on the 28th ult., to receive subscriptions and applications from gardeners and cottagers who wish to exhibit at the forthcoming show, which is to be held in the beautiful grounds belonging to the Priory, Hornsey. To Horatio Cooper, Esq., are the inhabitants of these northern suburbs much indebted for a personal canvass of the whole neighbourhood, which has materially strengthened the funds of the Society. The schedule of prizes to be competed for on the 4th of July next has just been published.

THE late frosts have done much damage to the peach crop in New Jersey and Delaware, U.S.

THE tobacco crop of Virginia now going into the American market is one of the largest and best raised for many years, and is commanding high prices.

A NEW impetus has been given to the fruit trade at Philadelphia by the large number of vessels which are constantly clearing from that port, with petroleum for the Mediterranean, returning laden with Messina and Palermo oranges and lemons, all of which find ready sale at from 50 cents to 5 dols. 75c. per box.

PROPOSED FORMATION OF A HORTICULTURAL LIBRARY AT SOUTH KENSINGTON.

We have been favoured by the Executive Committee of the International Horticultural Exhibition and Botanical Congress with the following correspondence:—

Botanic Gardens, Chelsea, April 11, 1867.

Sir,—I am desired by the Executive Committee of the International Horticultural Exhibition to forward you the enclosed copy of certain proposals for the disposal of the surplus funds now in its hands, adopted at its last meeting, and through which it is trusted the Society will derive some permanent benefit in acknowledgment of the facilities granted by your Council to the Committee at the time the extension of the Great Show was thought desirable.

May I beg that you will lay the proposals before the Council at the earliest opportunity, and that you will as soon as possible acquaint me with its reply.—I am, sir, your obedient servant,

THOMAS MOORE.

To the Secretary of the Royal Horticultural Society.

Extract from Minutes of Executive Committee, embodying the proposals above referred to.

1. That the surplus funds realized at the International Horticultural Exhibition of 1866 be applied to the establishment of a permanent Horticultural and Botanical Library, to be vested in seven Trustees, as hereinafter mentioned, and to be called the Lindley Library, in memory of the late Fr. Lindley, and his zealous devotion to the cause of Horticultural and Botanical Science.
2. £600 of this surplus to be applied to the purchase of Dr. Lindley's own library. As it appears that the Royal Horticultural Society has already provisionally secured possession of this collection with a view to prevent its dispersion, the Society to surrender it to the Trustees absolutely, in consideration of being repaid the sum of £600 in question.
3. The Society to consent to the Library now proposed to be formed being placed in the Council Room during the period of the continuance of their lease under the Royal Commissioners for the Exhibition of 1861.

4. Of the balance of the Fund (about £1,200) the Trustees to expend such sum as they may think expedient in the purchase or construction of book-cases and fittings for the reception of the Lindley Library, and any subsequent extension of it in the Council Room of the Society.
5. The Library to be available for consultation by Fellows, Members, and Associates of the Royal Horticultural Society, and other persons possessing rights of admission to the premises; also by gardeners on their producing a satisfactory introduction from their employers, and by young gardeners who may have passed or are preparing for the examinations held by the Royal Horticultural Society and by the Society of Arts. In the case of other persons to whom it may appear desirable to give the privilege of consulting the Library, the Trustees and the Society to agree upon the conditions under which the privilege of admission shall be given.
6. In the event of the books being kept under lock and key in the book-cases, the Society to entrust the custody of the keys to one of its officers, who shall be prepared at all reasonable times to give access to the books to those persons entitled to consult them.
7. The remaining balance of the surplus, after providing for the above items of expenditure, and setting aside any sum that may be necessary for contingencies (such as the preparation of the trust-deed hereafter referred to, &c.), to be applied by the Trustees to the purchase of further works to be added to the Library.
8. A trust-deed to be prepared for the purpose of giving effect to the present arrangement,—three of the Trustees to be appointed by the International Executive Committee (namely, the three Secretaries of the International Horticultural Exhibition and Botanical Congress, Mr. Thomas Moore, Dr. M. T. Masters, and Dr. R. Hogg), three by the Royal Horticultural Society (namely, the Treasurer and Secretary of the Royal Horticultural Society for the time being, and one other person to be chosen by the Society), and one to be added by the six Trustees above-mentioned jointly.
9. The Trustees to have the power of removing the whole of the books purchased under the trust, or added to the Library by presentation, together with all the book-cases, fittings, &c., referred to in paragraph 4, in the event of the determination of the lease held by the Society under the Royal Commissioners, and of making such arrangements as they may think fit for establishing the Library elsewhere."

Royal Horticultural Society, South Kensington,

April 17, 1867.

Sir,—The Extract from the Minutes of the Executive Committee of the International Horticultural Exhibition, respecting their surplus, which you were good enough to forward me, was yesterday read to the Council, and I am requested to convey to you their thanks for the very liberal proposition which your Committee has made.

The Council will, as wished, surrender absolutely the Lindley Library for the sum of £600; and in accordance with the terms of paragraph 8, has elected Mr. W. Wilson Saunders as the third and permanent Trustee from the Council.

With respect to paragraph 5, the Council would prefer that the admission of strangers should be regulated by the Trustees, and perhaps your Committee will find no difficulty in adding this slight concession to their very handsome present.

The Council desire me to add that in their opinion no better or more acceptable return could have been made to the Society for the facilities afforded to your Committee by the Council.—I have the honour to be, sir, your obedient servant,

HENRY SCOTT, Secretary.

To Thomas Moore, Esq., F.L.S., &c.

ROYAL BOTANIC SOCIETY.

FIRST GREAT SHOW, WEDNESDAY, MAY 29.

(Concluded from page 228.)

ROSES.—The trade class for ten pot-roses brought a lively competition, and secured for the enrichment of the tent several magnificent groups of plants. There could be no question about the superiority of the ten from Mr. Turner, for which the first place was awarded. They were of great size, symmetrical and uniform in shape, not over-tied, yet precisely finished. In respect of leaves and flowers, their quality was such as is but rarely seen; frosh to a marvel, and arresting attention instantly by a certain grandeur of carriage that it would be in vain to attempt to describe. The varieties were Charles Lawson (the grandest of all as to size, number of flowers, and general condition), Viconte Vigier, Anna Alexieff, Souvenir d'un Ami, Céline Forestier, Maréchal Vaillant, Baronne Provost, General Jacqueminot, Souvenir de la Malmaison, Victor Verdier. Second in this class, Mr. William Paul, with fine examples of Lord Raglan, Paul Perras (huge in size and perfect in finish), Madame Willermoz, Juno, Souvenir d'un Ami (with more colour than usual), Lælia, President, Charles Lawson, General Jacqueminot, Caroline de Sansal. Third, Messrs. Paul and Son, of the Old Nurseries, Cheshunt, with a superb Céline Forestier, Charles Lawson, Madame J. Daran, Paul Ricaut, Louise Odier, Madame St. Joseph (splendid), Baronne Provost, Sénateur Vaisso, Victor Verdier, Gloire de Dijon. Mr. Francis came in fourth with plants that had been respectable, but were now worn out, and the flowers falling to pieces. In the amateur class, the best plants came from Mr. Terry, gardener to G. Fuller, Esq., Youngsbury. Cut flowers were abundant in the annexed, Messrs. Paul and Son contributing a beautiful collection.

ORCHIDS.—The display of these was a pleasing feature of the show; but the truth must be told, that there was scarcely a plant in the whole of the bank that merited special attention or admiration from a professional point of view. Nevertheless, there were many beautiful plants, and amongst them many interesting species and varieties. Mr. Peuny, gardener to H. H. Gibbs, Esq., St. Dunstan's, Regent's Park, took the first place in the class for fifteen with a very pretty lot, in perfect health, and comprising a very good selection. They were as follows: Lælia purpurata, Acridis Fieldingii, Acridis virens, Dendrobium nobile, Phalenopsis grandiflora, Saccelabium curvatum, Vanda snavis, Lycaste Skinneri, Oncidium sarcodeus, Cypripedium barbatum superbum, Cypripedium levigatum, Dendrobium Parishii (with two spikes out, and more coming), Acridis Warcei, Calanthe veratrifolia, Odontoglossum phalenopsis. Mr. Wilson, gardener to William Marshall, Esq., of Enfield, took the second place with

an interesting group, comprising examples of *Cypripedium candidum* (with over a dozen flowers, the tails of which were thirty inches in length), *Eriopsis rutilus* (a pretty and valuable orchid), *Warzeowiczella discolor*, the charming *Odontoglossum Alexandræ* (with its chaste and peerless flowers), *Dendrobium densiflorum*, *Cattleya eitrina*, and others. The third prize in this class was awarded to Mr. Gidney, gardener to the Rev. W. Ellis, Hoddesdon. In this group, a good *Cattleya Mossiæ*, also the intensely bright orange-coloured *Lælia cinnabarina*, a good *Phalanopsis grandiflora*, and *Epiphora pubescens*. Fourth, Mr. Peed. The first prize for eight orchids was awarded to Mr. Hill, gardener to R. Hanbury, Esq., Ware. One of the most striking plants in this group was *Cattleya Skinneri*, with five spikes of eight flowers each, of the most lovely rose-purple colour; also *Cypripedium Stonei*, *Aerides Lindleyana*, *Phalanopsis grandiflora*, *Vanda suavis*, *Chysis Limminghii* (with five spikes), *Calanthe veratrifolia*, and *Vanda tricolor*. Mr. Wiggins second, with a good *Dendrobium densiflorum*, *Cypripedium hirsutissimum*, *Saccolabium præmorsum*, and others. Mr. Fairbairn and Mr. Young also contributed. In the collection from the last-named exhibitor, a beautiful *Phalanopsis Schilleriana*. In the trade class for six, Messrs. Veitch and Sons took first place with *Aerides Fieldingii*, *Cypripedium barbatum*, *Lælia purpurata*, *Cattleya Mossiæ superba*, *Cattleya lobata*. Mr. Williams sent *Cattleya Skinneri*, *Dendrobium nobile*, *Wallochianum*, *Angulosa Clowesii*, *Cypripedium barbatum*, *Vanda insignis*. Third, Messrs. Lee.

STOVE AND GREENHOUSE PLANTS.—The display of these was most profuse, and the immense variety of forms and colours found amongst them contributed in a very material degree to the enrichment of this splendid exhibition. In the class for ten, Mr. Baines took the lead with a faultless group; second, Mr. Peed; third, Mr. Kemp; fourth, Mr. J. Wheeler. In the class for six, first position was assigned to Mr. Donald, gardener to J. G. Barclay, Esq., Leyton; second, Mr. Coles, gardener to H. H. P. Henderson, Esq., Beckenham; third, Mr. Wilkie, gardener at Oak Lodge, Kensington. The trade exhibitors were Messrs. Lee, Rhodes, Glendinning, Williams, and Baxendale. In the class for six plants, Mr. Ward, gardener to F. G. Wilkie, Esq., Leyton, first; Mr. Smith, gardener to A. Anderson, Esq., Norwood, second. To enumerate subjects shown is impossible; the following were, however, more especially worthy of notice: *Medenilla magnifica*, grandly done, by Mr. Wilkie; *Acrophyllum venosum*, from Mr. Baines, extra fine; also from the same, *Genetyllis tulipifera*, trained to a huge balloon, and evenly covered with flowers; Mr. Peed had a fine *Allamanda grandiflora*, *Dracophyllum gracile*, and *Erica ventricosa magnifica*. In various groups there were noticeable examples of *Stephanotis floribunda*, *Diplandra crassinoda*, *Leschenaultia biloba*, *Statice Holfordi* and profuse, *Tetratecha verticillata*, *Clerodendron Thomsoniæ* and C. Balfourii, *Ixora aurantiaca* and *coccinea*, *Hæmanthus punicus*, *Pimelea decussata*, *Rhynchospermum jasminoides*, *Polygala cordifolia*, *Aphelaxis macrantha*, &c.—**FINE-FOLIAGED PLANTS** were plentiful; the contributors were Messrs. Lee, Williams, Wheeler, Fairbairn, Baines, Glendinning, Ward, and others. Mr. Baines presented his fine pans of *Sarracenias*; in other collections were *Rhopala*, *Yuccas*, *Aloes*, *Cordylines*, *Palms*, *Tree-Ferns*, *Alocasias*, *Cycads*, *Pandanads*, *Beaucarneas*, *Dracenas*, &c. Mr. Fairbairn showed *Alocasia zebrina*, so placed that its finely-marked stems were near the eye and the leaves overhead. When placed in this way it is a much more interesting plant than when tilted forward so as to display the upper sides of the leaves; it is then somewhat coarse.—**EXOTIC FERNS** were shown by Messrs. Williams, Taylor, Baines, and others. Mr. Ivery presented British Ferns, as did also Mr. James, of Isleworth.

NEW PLANTS.—Numerous certificates were awarded for new plants of merit. Amongst them were the following: *Sanchezia nobilis variegata*, from Mr. B. S. Williams and Messrs. Veitch. *Echites rubro-venosa*, from Messrs. Veitch, Mr. Williams, and Mr. Bull. *Dichorisandra mosaica*, from Messrs. Veitch and Mr. Bull. *Maranta illustris*, from Messrs. Veitch and Mr. Bull. *Coleus Veitchii*, from Messrs. Veitch, Mr. Bull, and Mr. Williams. *Panicum variegatum*, from Messrs. Veitch, Mr. Bull, and Mr. Williams. *Retinospora filifera*, from Messrs. Veitch. *Anthurium regale*, from Messrs. Veitch, Mr. Williams, and Mr. Bull. *Tillandsia argentea*, from Mr. Bull. *Amorphophallus nobilis*, from Mr. Bull. *Agave macrantha*, a fine broad-leaved, glaucous-tinted species, with distinct and formidable spines, will no doubt make a splendid plant when of sufficient age to show its characters: this came from Mr. Bull. *Blandfordia Cunninghami*, from Messrs. E. G. Henderson and Son; this is a valuable novelty, though it is by no means a new plant, having been discovered years ago by Mr. Allan Cunningham. It is a tuberous-rooted evergreen greenhouse plant, with glossy sword-shaped leaves, and a flower-scapa bearing a cluster of bell-shaped flowers of a brilliant copper colour. From the same, the new orange-leaved elm, *Ulmus campestris aurea*, and the new golden-leaved alder, *Alnus glutinosa aurea*, both of them beautiful trees. Mr. Wilson, gardener to W. Marshall, Esq., brought a good variety of *Mitonia spectabilis*, called *rosea*, and a nice plant of the rare *Dendrobium thyrsoiflorum*.

New Pelargoniums.—The new pelargoniums made a distinct and interesting feature, and amongst them were certainly some beautiful and useful varieties, but only two or three were remarkable for distinctness and high quality. From G. W. Hoyle, Esq., Reading—*Man of Mark*, small, neat, quite finished in smoothness and colour, rosy carmine, with small black spots, the top petals dark; first-class. *Victor*, large, fine form, pinkish rose, white throat, dark top; first-rate. *Example*, medium size, perfectly circular, smooth and finished, rich carmine, white throat, dark top; first-rate. From Mr. Nye, gardener to E. B. Foster, Esq., Windsor—*The Emperor*, very large and showy, fine broad petals, but the top petals rather curled at the base, soft clear pink, the top petals reddish pink, with small dark blotch; a handsome flower. *Rob Roy*, large, fine form, smooth, carmine-pink, with superb top, dark shading to lake; one of the best of the season. *Grande*, small, perfect form, pale pink, dark top; first-rate. *Northern Star*, small, orange-red, top dark, rough. *Troubadour*, large, with a slight fold at base of top petals, clear salmon, top petals reddish salmon, with small maroon blotch. *The Peer*, large and fine, only one flower fully expanded to judge it by, and that beautifully formed and quite smooth; colour pink, heavily overlaid with lake veins, top petals maroon-black, with sharp whitish edge; very showy and fine, but not enough of it for a final decision. *Conquest*, in the style of *The Peer*, but apparently wanting in smoothness; very handsome and effective. *Autocrat*, large, rough, salmon-flesh, dark top; pretty. *Magician*, large, good form but scarcely smooth, clear rich carmine, top richly veined; fine for colour. From Mr. Wiggins, gardener to W. Beck, Esq., Isleworth—*Hermite*, large, fine form, blush white, top petals maroon shading to lake, richly veined; first-rate. *Lady of Quality*, small, extremely neat and perfectly finished, clear red with lake veins, top very dark, with sharp red line;

first-rate. *Aspasia*, large, good form, wrinkle in top petals, rosy pink; top petals dark, white throat. *Orange Spot*, small, orange-scarlet and black spots, dark top; good for colour. *Mignonette*, small and neat, top petals wrinkled, lively and lovely shade of carmine, top petals blotted black; very rich. *Armida*, neat, rosy carmine, dark top. *The Cardinal*, large, rough, orange-red. *Calypso*, small, clear salmon-red, dark top; second-rate. *Queen of Roses*, large, good form but not perfect, intense pure carmine, with shade of violet in throat, top petals with dark blotch. *L'Empereur*, carmine-pink, dark top, pale throat; pretty, but second-rate. *Electra*, large, good form, pale flesh, dark top shading to lake, white throat; a fine flower, peculiar and striking. *Aurora*, neat, good form, lake, dark top; good. From Mr. Turner, of Slough—*Thros Fancies: East Lynne*, a pretty flower, large, rich rosy carmine, whitish throat; *Marmion*, neat, but scarcely smooth enough, reddish carmine, whitish throat; *Pink of Perfection*, small, magenta, pale centre. These three varieties appear to be eminently adapted for specimen culture. From Messrs. Dobson and Son, Isleworth—*Magnet*, medium size, quite second-rate in form, flowers in huge trusses, colour fiery carmine and black; one of the most telling varieties for decoration ever seen.

New Zonale Pelargoniums.—An immense number of new varieties in all the classes were shown; to describe them all would be waste of time and space, and a needless tax on the patience of readers. But a certain number must have attention, and if the following should be thought too long a list, it must be remembered that there is much curiosity and inquiry in reference to these plants, and the only way to sift out the best from the thousands offered us is to go through them carefully as opportunities happen. From Mr. Watson, St. Alban's, a series of Tricolors and others: *Miss Gladstone*, leaf top deeply lobed, colours good, in the style of Mrs. Pollock. *Miss Watson*, leaf small, flat, round, no lobes, pale yellow margin, fiery red zone, green disc, a few radiate bars; first-rate. *Mrs. Dix*, like the last, more black and less red in the zone, but first-rate. *Gipsy Bride*, in the way of Luna, but with larger leaf.—From Mr. John Mann, the Nursery, Brentwood, a large collection of zoned, bicolored, and tricolored varieties. The most remarkable among them was one called *Leah*, the leaf large, round, and flat, clear yellow margin, broad brilliant zone of brick-red, not far removed from Egyptian red, disc green and yellow rays. This is an extraordinary variety as shown, but no dependence must be placed on this description for the present, as the plant was evidently a seedling showing its first break of colour, the lower leaves being deep green. If it should keep to its present character, it will be the leader in a new race. *Palladium*, sulphur yellow margin, zone chestnut and dark, disc dark green. *Idothea*, in the way of Luna, but not so good. *Fair Graham*, in the way of Italia Unità, much colour in the young leaves, the old leaves washy. *Mario*, large leaf, broad sulphur margin, broad rufous red and olive zone, green disc. *Little Wonder*, very small and very pretty, a miniature Lucy Grieve; first-rate. *Lady Farnham*, large round leaf, yellow margin, very broad zone of black, amber, and red, green disc. *Dido*, a miniature tricolor, straw edge, pink zone, dark disc with radiate bars. *Rosa*, dwarf habit, very compact and neat, pale yellow margin, zone black and red; good. *Diana*, dwarf and compact, leaves round, edge sulphur, zone red and dark, disc radiate; very pretty. *Prince of Wales*, fine bold leaf, in the way of Mrs. Pollock. *Standard Bearer*, a middling good tricolor, in the Mrs. Pollock style. From the same a series of zoned varieties, with attractive flowers. *Lord Derby*, a fine dark zoned leaf, flowers large, finely formed, stout, smooth, brilliant scarlet; unquestionably one of the finest scarlets ever shown. *Juno*, a neat habited Dr. Lindley. *The Baron*, a good scarlet crimson nosegay. *Orion*, a good scarlet. *Christabel*, salmon red, flowers good. *Eugénie*, good style of growth, leaves distinctly zoned, flowers large, well formed, and stout, colour pale salmon; good.—From Mr. William Paul, Waltham Cross, *Waltham Nosegay*, in the style of Cybister, with carmine shade. *Dr. Hogg*, a fine nosegay, with massive trusses and substantial flowers; a fine shade of violet red. *Peach Nosegay*, a good truss of clear pink. *Jason*, a had or good self, yellow leaf; it is impossible to judge this except in a bed or ribbon-line.—Mr. Paul also contributed a beautiful lot of Standards, most of them tricolor varieties; they are effective ornaments for the conservatory.—From Messrs. F. and A. Smith, Dulwich, a large and beautiful collection. *Brilliant*, in the style of Luna, with a fine bright orange-brown zone; likely to be of the greatest value as a bedder. *Sunshine*, in the way of Sophia Dumaresque, first-rate, the colouring bright and even. *Ariel*, a convex leaf, bold, clean, creamy edge with tinge of rose, dull green disc. *Wonderful*, quite in the style of Mrs. Pollock, clear lemon edge, rather zig zag zone of bronze and bright red, green disc; fine. *Miss Louisa Smith*, like the last, so much so that no one could choose between them having only a plant of each. *Sylph*, very delicate and pretty, pale cream margin and faint rosy zone, dull disc. *Glory of Dulwich*, a small tricolor, with narrow yellow margin, broad bright red zone, through which break a few dark rays; this is one of the best of its class, and cannot fail to become a general favourite. Two or three guineas is nothing for the first start to get a stock of such a thing as this. *Sunrise*, small, round, flat leaf, lemon yellow margin, bright red zone, green disc, radiate bars breaking through to the edge. *Impératrice Eugénie*, in the way of Italia Unità, the young leaves cupped, all the leaves wrinkled. *Queen Victoria*, small, neat, flat leaf, margin varying from cream to gold, red zone; neat and pretty. *L'Empereur*, large flat leaf, quite round, without lobes, margin lemon yellow, zone clear red, with dark shades where rays from the disc break through. *Peace*, large wrinkled leaf, creamy margin, the zone very dark with flashes of flame red; superb for colour, but otherwise faulty. *Sunray*, in the style of *Glory of Dulwich*, leaf quite flat and round; a dull tricolor. *Delicata*, pale cream margin showing tints of pale rose, disc dull green. *Champion*, a very large round leaf, rather convex, margin sulphur, plenty of red in the zone; fine. *Cleopatra*, in the way of Luna, and first-rate. *Mr. Grieve*, medium-sized leaf, pale yellow margin, red zone, rays of yellow and green extending from centre to circumference; handsome and distinct. *Black Prince*; this is a member of the race of the zoned scarlets, and is peculiar and striking; the leaf has a broad black zone almost covering it, the remaining parts being of a deep black green; the flowers are first-rate in form and substance, colour bright orange red. It stands apart from all the other scarlets by the contrast between its black leaves and dazzling flowers.—Mr. Stevens, of Ealing, sent a batch of large-leaved tricolors, but they were of the wrong sort, and nearly alike, the leaves large and flat, margins creamy buff or pale yellow, zones pale red, and dark green discs; rather coarse, yet weak in colour, and wanting in character.

MISCELLANEOUS NOVELTIES.—There are always some subjects that it would be an error to class as new plants, and some such heading as the above becomes necessary for them. Mr. Bull sent a group of new varieties

of *Lobelia erinus*. *Rosy Gem* is much like the variety *Messrs. Carter* sent out a few years ago, called "*Kermesina*," and which nobody would buy, though it was exceedingly pretty: this variety has plenty of purplish rosy flowers. *Celestial*, large, light blue and white; no good. *White and Blue*, very much white, slight tinge of blue; no good. Another not named, and the best of the group, has very pretty flowers, which are heavily striped blue on a white ground.—From Mr. W. Paul a beautiful collection of *Aucubas*.—From several exhibitors, but from Messrs. E. G. Henderson in particular, the *Golden Feather Pyrethrum*, which is a variety of *P. parthenifolia*. It has been a good deal pooh-pooh'd by knowing people, but is likely to be as useful for bedding as many of the best yellow-leaved geraniums, with the advantage of being absurdly cheap and wanting only frame protection all winter, and no protection at all in sheltered dry places. *Jasminum officinale aurea*, richly variegated with gold blotches. A good variegated form of *Althea frutex*, very much white and cream; and a finely variegated *Ligustrum ovalifolium*, the greater part of the plant being of a rich gold colour. S. H.

CAMBRIDGE HORTICULTURAL EXHIBITION.

The exhibition held in the beautiful grounds of St. John's College, Cambridge, on the 23rd of May, was one of the most interesting and successful in the long and bright annals of Cambridge horticulture. The day was piercingly cold, but it was bright and breezy enough for a yacht race. The question arose, would there be a company? and this question was answered as the day wore on by the pouring in of visitors, who at last completely filled the great tent and covered the beautiful lawn, on which the band of the Coldstream Guards, with Mr. F. Godfrey leading, warmed the atmosphere with melody, and sent the wind on its journey westward whistling a pleasant tune. To a stranger, the out-door attractions were the most fascinating, for the grounds of St. John's College are exquisitely green, and pervaded by a quiet which is almost religious. The glorious elm-trees,—Cambridge is a paradise of elm-trees—the ample breadths of emerald-green turf, the romantic shadows, the beautiful and various architecture, and the clear winding Cam, which takes several turns through the grounds, are all so charming severally, and so happily blended into an harmonious whole, that it is a question, when judges are invited from a distance, if they should not pay instead of being paid, for enjoyments of this sort are not over plentiful. In the tent there was a very fine display of plants and flowers: a centre table filled with stove and greenhouse plants, in the midst of which Azaleas made a brilliant show, and on either hand continuous banks of plants, comprising amongst them many fine specimens and examples of superior cultivation. The best group of twenty plants in bloom came from Messrs. Wood and Ingram, second Messrs. Hudson, third Mr. Snell. The best ten came from Mr. Snell, second Mr. J. J. Chater. The best specimen from Mr. F. Butler, second Mr. J. J. Chater, third Rev. Dr. Clark. Best six, Messrs. Hudson, second Mr. Butler. Best three, Rev. Dr. Clark. These collections made an attractive bank. Amongst the subjects shown we noticed good examples of the sweet-scented *Rhynchospermum jasminoides*, in most cases trained out on wire balloon-shaped trellises, a method well adapted to its sub-scandent habit. *Pimeleas*, *Eparis*, *Hoya carnosa*, *Polygala cordifolia*, *Genetyllis tulipifera*, *Eriostemon buxifolia* and *pulehella*, *Boronia serrulata*, *Kalmia latifolia*, *Kalosanthes*, *Scarlet Leschenaultia*, and various ferns, were noticeable for their beautiful condition and effective staging. A *Medenilla magnifica* in Messrs. Wood and Ingram's lot won many plaudits for that eminent firm. There were fine examples also of *Clerodendron Thomsonia* and *C. Balfouria*, covered with their elegant flowers. In Messrs. Hudson's lot, a *Rhododendron*, labelled "*aureum gloriæ florum*," presented a peculiar and beautiful appearance in spite of its absurd name, the colour being a ghostly buff, with pale yellow top petals overlaid with ghostly olive spots. For conservatory decoration this variety is most desirable, but quite unfit for out-door cultivation. Of orchids there were a few good species in these groups, more particularly of *Dendrobium nobile* and *Calanthe veratrifolia*. In the classes for orchids, Mr. J. J. Chater and Messrs. Wood and Ingram were the principal exhibitors. In the classes for foliage plants, Messrs. Wood and Ingram took the lead, Mr. Hurrell, Rev. Dr. Clark, and Mr. J. J. Chater following close. The favourite plants were *Caladiums*, amongst which *Chantini* shone out conspicuously as by far the best. We were pleased with a plant of *Pœcile*, which, although rather burnt through insufficient shading, bore a quite commanding character; the leaf is large, with carmine red veins and pale red centre, the margin dark dull green. *Houlettii*, *Wightii*, and the lovely *Belleymeii* were also well shown. With the *Caladiums* were associated *Crotons*, *Dracæna*, *Marantas*, and one of the best plants ever shown of the variegated *Alcacia macrorrhiza*.

In the classes for geraniums, the principal exhibitors were Richard Heady, Esq., Messrs. Wood and Ingram, Messrs. Hudson, Mr. Hurrell, Mr. F. Butler, and Mr. J. J. Chater. An interesting point arose in judging the groups of six show varieties. Messrs. Wood and Ingram put up six convex, uniform, finely-finished plants, solid with leaf and bloom, and the colours well chosen for effect, both separately and as a group. Mr. Heady put beside them six fine plants that were neither so compact, so perfectly rounded off in convex outlines, nor so effective in respect of colours. But Messrs. Wood and Ingram's varieties were decidedly inferior to Mr. Heady's; the flowers were rough though showy, whereas Mr. Heady's flowers were large, round, flat, and of the true florists' type; indeed, Mr. Heady, as everybody knows, could not endure a rough flower, no matter how gaudy its colours. How are these to be placed? The judges decided in favour of Messrs. Wood and Ingram's *plants*, placing them first, and Mr. Heady second. In the show classes there were fine examples of *Fair Rosamond*, *Sir Colin Campbell*, *Sanspareil*, *Lilacina*, *Fairest of the Fair*, *Rosebud*, *Spotted Gem*, *Admiration*, *Empress Eugénie*, *Guillaume Severeys*, *Lady Canning*. In the classes for fancies, we noticed *Cloth-of-Silver*, *Countess of Waldgrave*, *Evening Star*, *Godfrey Turner*, *Lilac Queen*, *Madame Sainton-Dolby*, *Madame Teitjens*, *Negro*, *Modestum*, *Roi des Fantaisies*, *Undine*, *Delicatum*. Herbaceous and shrubby *Calceolarias* were shown in plenty, and in beautiful condition. Mr. Hurrell took first first place in the herbaceous class with well grown plants, which were too nearly alike; indeed, the herbaceous varieties were all apparently from inferior strains, though admirable as to condition and bloom. Mr. J. J. Chater, Mr. Clarke, and Mr. F. Butler, contributed pretty examples. In the class for shrubby kinds, Mr. Richard Heady stood all alone in his glory, with magnificent examples, mountains of colour, and in condition as to contour and leafage that left nothing to be desired. As we considered the her-

aceous varieties below the London standard, so we thought the shrubby kinds from Mr. Heady far in advance of the same standard. One called *Diana* presented a remarkable appearance. It is in the style of *Lillio*, with immenae trusses, and large round flowers of the purest yellow. *Pot Roses* were shown in a fine condition by Mr. Turner, first for six; Mr. Cumming and Mr. Wallis best single specimens, and Mr. R. Heady first for three. There was nothing new amongst them. *Azaleas* were plentiful: first in the class for six, Messrs. Hudson, second Mr. Heady; in the class for three, first Mr. Heady, second Mr. W. P. Snell; best single specimen, Messrs. Hudson: these were good throughout, rich in colour, and in good training. *Cinerarias* were past their season; the best came from Mr. Heady. *Rhododendrons* were well shown by Messrs. Hudson, Mr. F. Butler, and Mr. Chater; *Heaths* by Mr. Snell, Mr. Heady, Mr. Cumming, and Messrs. Wood and Ingram.

Cut flowers were not plentiful, but such as were shown were good. Mr. Heady presented the best twelve tulips, as might be expected; and from the same exhibitor came the best six, the best three, and the best one. Mr. Barrett, Mr. Wallis, and Mr. Serjeant, followed with beautiful blooms. *Anemones* were shown by Mr. Ingle, Mr. Serjeant, and Mr. Cross. *Pansies*, by Mr. Serjeant Wallis, Mr. Serjeant, Mr. Swan Wallis, Mr. Chater, and Mr. Lilly. There were numerous bouquets and baskets of flowers, which possessed their several points of interest and attraction. Some excellent vegetables and salads were shown in the cottagers' classes. The judges were Mr. Lightbody of Falkirk, Mr. Mudd, curator of the Cambridge Botanic Garden, Mr. Riccard of Cambridge, Mr. Shirley Hibberd, and another gentleman, whose name has escaped our recollection.

A DAY IN THE WEST OF LONDON:

BUCKINGHAM PALACE GARDENS. THE FLOWERS IN HYDE PARK.

On Saturday, the 18th of May last, an impulse irresistible, but not unaccountable, took possession simultaneously of Mr. Crute and myself that we would go and see what was being done for the out-door comfort and consolation of the poor rich people, who during the severities of the London season commonly take air and exercise in the parks. All in pure philanthropy, of course, and very justifiable I am sure, considering how much is done for the poor in these times, and how generally neglected are the rich. For *them* (that is to say, for the rich people) there are no scripture readers, no tracts, no special services, no free drinking fountains, no provision of tea and cake, and amusing speeches, each with a lovely moral at the beginning or the end; no hard free seats near the door, with cold pavement for the feet and a cutting draught to act upon the nape of the neck, in the parish church; no dissolving views and no Christmas boxes. To compensate for these spiritual, moral, and material voids in their earthly lot, they ought to have the consolations of a little nice gardening; and in our anxiety to be assured that this much was done for them, we (Mr. Crute and self) rejected our customary late Saturday dinner and extra half pint of Bordeaux, and, with nothing beyond a couple of chops each and a little brown sherry at the hour of noon to support us on our mission, started together for the scene of our investigation. On the way, the thought struck us that we ought to call upon the Queen first; true loyalty made us anxious about our beloved sovereign's welfare in respect of out-door pleasures. So we turned aside from Piccadilly to Pimlico, having the evident approval of Field-Marshal the late Duke of Wellington, as he smiled down from the cloud-capped tower where, as a mounted sentinel on a house-top, he does duty faithfully at Hyde-Park Corner. As Mr. Matthews used to say of the country man whose "feather died detested and agin his will," that he "went to the Temple and knocked at the door, and the gentleman com'd out his sen," so we went to the Palace and rang the bell; and instead of Her Majesty, as is the custom with great people in receiving distinguished visitors, opening the door, Mr. Wynne, the head gardener, came out instead and gave us a welcome. We then learned that the Queen was at Windsor, so we could not dare to cherish the thought that there was any decline in the observance of etiquette at Buckingham Palace. Mr. Wynne is too well known to the horticultural world, and especially to the readers of the Magazine, to need any introduction. Every one of our readers is always glad to hear mention of his name, and still more glad when his able and experienced pen is employed in these pages for our mutual edification.

We very soon commenced a tour of the grounds, and I can assure you that the beauty of the place is something astonishing, if the scene within be fairly contrasted with the scene without. It need not be said that Buckingham Palace is built in a hollow, and is densely walled in by houses on all sides except that which faces the park. The site might most appropriately be called the "valley of smoke" all the spring and summer, and in autumn the name could be changed to the "valley of fog." That the Queen should now stay at Buckingham Palace only as a matter of convenience, and fly thence to Windsor, or Osborne, or Balmoral, the moment the business calling her to London is concluded, ought not to surprise any one who has surveyed the wondrous semicircle of roofs and chimneys to be seen from the centre of the garden, or who will take the trouble to push through a thicket of trees in order to become clothed with soot from contact with them. It is a wofully sooty place—it is literally bathed in smoke; and many essentials of a good garden have ceased to be possible since the houses have multiplied in Pimlico, and the fields and gardens have disappeared. Nevertheless, for all this, it is a most charming spot, laid out in the English style, rather artificial in some places, especially in the boundaries of the lake, and the proportions and dispositions of the mounds, yet showing ample breadth of treatment, and presenting many beautiful scenes and bits of scenes, such as we look for in a landscape garden. The belts of shrubs, the knolls, recesses, and isolated objects near the garden entrance to the Palace are as beautiful as in any park or garden in the metropolitan district; and I believe I may venture to assert there is not in London, exposed to a smoke-cloud so constant and so dense, and so unfortunately situated as to make a garden at all compatible with this in freshness, beauty, and interest. It is rich in trees and shrubs, everywhere admirably kept, and its smooth green lawns are a perpetual testimonial to the skill and fidelity of our excellent friend Mr. G. Wynne, Her Majesty's gardener.

We went through the gardener's garden first, and saw plenty of those subjects to which Mr. Wynne has more especially directed his attention dahlias, chrysanthemums, fuchsias, and geraniums. The dahlias were already planted out, and chrysanthemums were pretty forward in pots, for specimens hereafter. In the greenhouses there we found extensive

collections of the more useful subjects, and saw our friend's seed-beds of fuchsias, geraniums, chrysanthemums, and lobelias, in which were many good novelties that the public will hear of in time. Mr. Wyness has long laboured in the improvement of the fuchsia, and we are indebted to him for many of our best varieties. Several pretty varieties of *Lobelia erinus* took our attention; but it is only when bedded that such things can be judged, and so we soon got away to the woodland walks, and broke their silence by three talking like one. Comparing the garden with the building it embellishes, it has the merit of consistency, for it presents no such diversities of style as the Palace itself, where Mr. Bloor's rich German front is mixed up with the trashy architecture of Nash. Indeed Buckingham Palace, architecturally considered, is the most heterogeneous jumble of costly, florid, mean, shabby, and vulgar work ever seen in modern times; and, by the way, modern times are sufficiently famous for architectural failures. In every part of the garden Cheerfulness reigns in company with Quiet. We see here the marvellous effect of trees in subduing the harshness of artificial undulations and of harmonizing elements that must originally have appeared incongruous. We commence our walk by ascending a hill, which is thickly clothed with trees. As we descend on the other side we cross a bridge to a pretty pavilion, which was the favourite breakfast room when the Prince Consort was our Queen's companion and the master of this beautiful London garden. This pavilion is octagonal, and is superbly adorned, the compartments being richly gilt in a series of panels, and in every panel is a highly finished fresco by some one of our greatest artists. From the front of this pretty structure there is a charming view extending over gently undulating ground, to the right being an apparently boundless extent of mixed tree and shrub, like the outskirts of a wood; in the foreground tall elms and a great sweep of turf, and in the background the still lake with its wooded islands and rich depth of timber on the opposite shore. No one unacquainted with the boundaries and the immediate proximity of houses could possibly suppose that these gardens comprise only fifty acres in all, so judiciously is the space opened for affording the eye free range from the principal points of view, that is to say, from all points near to the Palace. There are full twenty-five acres of grass-turf, and immediately in front of the Palace itself, that is to say, the garden front, the turf stretches right and left without a break, the water in front, and the shrubberies on either hand, forming its boundaries and screening off the blocks of buildings that hem in the garden.

Having reached the Palace, we took a stroll through the conservatory. This is a hideous *architect's* structure. No horticulturist, no architect, indeed, who had ever grown a cucumber could have built such a sepulchre and called it a plant-house. Mr. Wyness manages to keep it gay, and there are many beautiful plants in it; but I think I would sooner turn my back upon gardening altogether and become a milliner or a lord than give my mind to the cultivation of a sixpenny geranium in such a house. It consists of solemn pillars with heavy capitals, and a very solemn and very heavy cornice with glass between and above. It might do well for ferns, but for any kind of plants requiring a good light it is as unfit as a coal-mine. It is just such a blunder, only perhaps worse in degree, as the engine-room-looking structure once intended for oranges, and now used as a timber museum, in the Royal Gardens at Kew. I am glad I have seen this "conservatory," because I can now understand how it is that the Queen so seldom stays in London. I do not think any person, rich or poor, possessed of any degree of taste could endure to see daily such a plant-house, except as a sheer sacrifice and for some other end. The Royal Family lived here much in the days of the Prince Consort, but then there was nothing gloomy in the round of his daily life, and an architectural abortion would have some beauty in it by contact with his powerful and elegant mind.

Choice trees abound in the shrubberies. There are many fine thorns, and indeed of flowering trees generally a rich assemblage. Coniferous trees are not plentiful, which is an advantage, for it is impossible they should thrive in so dense and constant a cloud of smoke. The big elms are declining in vigour, but many of them are still beautiful and stately, and their grand shadows seem to magnify the amplitude of the grassy space to which they serve as a foreground. The grass-turf is kept in beautiful order by means of one of Green's 42-inch horse machines, which Mr. Wyness describes as doing capital work. It is somewhat of an error, though, to speak of this as "grass-turf," for in some places the predominating plant is yarrow, and in one spot near the margin of the lake there is about an acre of camomile, which far surpasses grass in greenness, closeness, and felt-like texture; it has the beauty of spergula, and is far less trouble to make and keep. Respecting the wild and tame birds, and many other interesting features of these gardens, I must refer readers who wish for further information to an article in the GARDENER'S MAGAZINE of August 26th, 1865; for our way now lies towards Hyde Park, to see what is going on there for the delectation of the upper ten.

It will be remembered that the display of double tulips and other spring flowers in Hyde Park was principally confined to the walks immediately adjacent to Park Lane, more especially in close contiguity to Stanhope Gate. No sooner was that display exhausted than the ground was cleared and planted with summer bedders; and another slip of ground, namely, that lying parallel with the high road between Hyde-Park Corner and Albert Gate, became splendid with the bloom of thousands of rhododendrons. We gave notice of the blooming of these in good time for our London readers to see them, and we trust that many took advantage of the opportunity, for it was a grand display, and is not even now quite past. This feature is the more interesting at the present time because of its newness, for the slip lying between Rotten Row and the carriage drive which proceeds from Apsley House directly westward has but recently been reclaimed from a semi-waste condition, and is newly formed into a garden. Mr. Mann, the superintendent, was unfortunately laid up with illness, and we met Mr. Chamberlain, his representative, making now a party of four, and we went into the enclosure and had an enjoyable look about us. It is well to traverse the whole length of the ground, and look beyond it to a half wild hollow where usually may be seen a number of sheep grazing. Now, just such a dirty savage spot was this skirting ground before Mr. Mann bestowed his skill upon it; and observe the difference. The ground undulates throughout in very nearly the same configuration as it had before the work began, so no one can gain a point in overwise criticism by saying that hills were heaped up and hollows scooped out to make a sham picturesque. Yet the undulations contribute in an eminent degree to the beauty of this garden, and have been made the best use of in the planting. Let us observe, first, that there is an even and close green turf throughout. We are informed by Mr.

Chamberlain that this is true London-grown turf, and is far to be preferred for London use to the best turf from the country. It is the practice to sow down a few acres in some part of the park every year, expressly for special purposes such as this, and when the ground is stripped of three or four year old turf the ground is sown again. Country turf, if well chosen, would look better at first, but would not last; it becomes patchy and bald after a few months' life in London, and never can be restored. Herein a hint perhaps to some of our London readers who are accustomed to difficulties of the kind. The principal embellishments here are rhododendrons, but there are many flower beds richly planted, and a few beautiful specimen hollies and other ornamental trees. The rhododendrons are the governing elements, and there is no such collection anywhere to be found in the metropolis. There are belts of unnamed hybrids of Catawbiense of fine quality and every shade of colour, the so-called "scarlets" being most largely employed. There are also beds of select dwarf species that contribute to vary the scene and afford in their seasons sheets of colour. But the standard rhododendrons are the most stately and splendid embellishments of this series, and they comprise some of the best ever grown, and are by no means few in number. On every hand may be seen trees, with straight stout stems, four to six feet high, carrying round compact heads three, four, and five feet through; some, indeed, of considerably larger dimensions—noble objects irrespective altogether of their magnificent appearance when in flower. As to the behaviour of these trees this season, nothing could be more satisfactory. They have been literally solid with bloom, gigantic bosses of the richest and most varied colours. Those which we especially noted as good were:—*Roseum elegans*, which is for general purposes the best of all, its fresh colour and abundance of bloom render it a general favourite; John Waterer, a fine dark crimson, flowering late, is fine; *Atrosanguineum*, blood red, with grand foliage, is at once peculiar and gorgeous; *Barclayanum*, deep crimson; *Delicatissimum*, blush with a warm tinge of pink; *Maculatum grandiflorum*, rosy lilac with showy spots; Prince Albert, clear lake, fine foliage; Sir Charles Napier, rose richly spotted; Victoria, deep rich claret, free to bloom, and fine habit; and *Blandyanum*, rosy crimson—have all been noticeable for distinctness, richness, and profusion of flowers. It must not be supposed that these trees are doomed to languish in the London smoke. The fact is, if rhododendrons are properly treated in the first instance, they thrive in London; and Mr. Chamberlain assured us that the Catawbiense breed, after they have been in London a year or two, cease to drop their leaves during frost, and actually appear to be strengthened in constitution by town life. No one who has seen—as some hundreds of persons have—the hybrid rhododendrons this season at Stoke Newington, and which have been growing in the same bed for ten years, can doubt the suitability of this noble evergreen for the London atmosphere, or entertain any fear of their well-doing in Hyde Park. The Hyde-Park rhododendrons are all planted in Wanstead peat, which is the favourite stuff with us North Londoners, because it happens to be near at hand and costs little for carriage. But it must be good also, or it would never have been selected for this particular purpose at Hyde Park. Some of the standard trees here have cost twenty to thirty guineas each, and the smallest of them must have cost from three to five guineas each; and they are well worth these prices, for there are many long years of growth in them. Much skill and time have been bestowed in making straight stems and round heads, and finishing them off for such an artistic use as we now see them put to. They were all supplied by Messrs. Waterer and Godfrey, of Knap Hill, Woking; and on the same 18th of May, when the rhododendrons were bursting their sheaths and showing their first trusses, bedding was in progress in the Park, and tens of thousands of plants were put out to risk it. How the frost of the 23rd and 24th served them I do not know, but there were some splendid effects produced there, and that by instantaneous colouring, the practice here being to put out *large plants*, and to *plant them thick*, so that no sooner are the pots cleared away and the workmen gone than the beds are pretty nearly as bright and rich as they will be at any time throughout the summer. Here were *Stellas*, Mrs. Pollocks, Lunas, and other such things, planted at about nine inches to a foot apart, the edges of their outermost leaves touching already, so that there is no waiting till the ground is covered; that is accomplished in the first instance, and one of the gravest objections to the bedding system, namely, the *waiting for effect*, is abolished. But, oh, how the old practitioners are ready with their protests against this system, that it consumes three times as many plants as would suffice at the customary distances, and that long before the season is over the plants will kill each other by overcrowding. Well, good friends, these objections are sound perhaps; but Mr. Mann has anticipated them, and, with the quick discernment and original spirit that marks all his movements, has provided against the possibility of exhaustion at either end of the routine. He meets the first objection, that there must be three times as many plants as on the wide interval system, by simply growing enough. If one hundred thousand would do at 18 inches, and he wishes to plant at 6 inches, he had but to grow three hundred thousand, and that is the way he conquers difficulty No. 1. At the other end of the story, he does not allow the beds to become yellow and flowerless by overcrowding, but when the plants are worn out he takes them up and *plants again*. Think of that, O ye *Desidiosos*, who chuckle with self-satisfaction when your annual crop of geraniums and calceolarias is beginning to show a little colour at the end of June! Here are three crops of flowers in the period between March and September, and no waiting for effect, in other words, *no intervals between them*. See the bedding *now*, and judge for yourselves. Why, when we four—namely, Mr. Crute, Mr. Wyness, Mr. Chamberlain, and self—went over the ground the beds were already rich with the colours required of them; *Stellas* were full of flower, and Lunas full of leaves. But the third crop; well, we can soon dispose of that, by saying that it consists of asters, stocks, balsams, and sub-tropicals. Yet one thing more says *Desidiosus*, "Mr. Mann has the means to do all this; take away his means, and where is he?" Well, it is true he has means, yet perhaps not such a prodigality of means, after all. I suppose he has enough, for I never heard a word of complaint. But he has also some other aids to success; he has genius, industry, pluck, foresight; take away his brains, and where is he? We were so inspired by curiosity that we went on towards the long walk in Kensington Gardens, had a look at the beautiful plantation of flowering ashes (*Ornus Europæus* and other species) there, and the named collection of trees and shrubs. Then went on to Kensington Palace, and experienced a change of sensation. I beg pardon; I remember, Mr. Chamberlain had parted from us, and that Mr. Crute and Mr. Wyness were not cynical at all, but generous and appreciative. Somebody (I leave you to guess who) was in a sneering mood up there; for what the deuce do you think some past government or first

commissioner has been and gone and done, to illustrate the persistency of muddle as an element of official business in England? All one side of Kensington Palace is a vast nursery; yes, close under the windows of one wing ranges of greenhouses, pits, plunging beds, the odour of manure and steaming grass-mowings, the creak of the wheel-harrow and the workshop eteteras, to improve the look-out from one of the royal palaces. I expressed my opinion about the relation of this fact to the fitness of things, but nobody agreed with me, and I can only now say that if Prince Teck, who resides in Kensington Palace, likes to open his windows on a great nursery which consists wholly of working stuff with not a scrap of anything ornamental about it, we ought to be very sensible of the compliment he pays to our craft. If you were to make me a prince to-morrow, and give me Kensington Palace for a residence, I would not move in my sticks or return thanks for benefits received till the nursery was cleared away, and the ground was planted as a garden.

But the nursery. It is like everything else connected with the decorative department of Hyde Park, a model of good management, and peculiar in one respect, and that is in power to turn out immense quantities of plants in a fine condition for the several purposes for which they are required. We saw here houses crammed to repletion with Castor-oil plants, India-rubber plants, Solanums, Wigandias, Cannas, Daturas, Palms, Ferns, and other such noble subjects, in course of preparation for planting or plunging out of doors. A better lot for size and health there could not be. Of bedders generally there was still an immense quantity, though on that same day many thousands had been planted. Nine-tenths of all the bedding plants are grown to as large a size as possible in large 60-sized pots, that is the largest size they can afford. They carry out at one turn nearly 2,000 plants of this size in one barrow, without breaking a stem or bruising a leaf. When I said "barrow," however, I mean a gigantic tray on four wheels, drawn by a strong horse; the said tray consisting of a flat wood flooring, with sides and ends about six inches deep. The tray measures about twelve feet long by five feet wide; and Dobbin takes it carefully along the drives to the places where the plants are wanted, and draws close up to the heds, and thus the plants are scarcely shaken in their transit from the pits to the ground.

The greater part of the geraniums, verbenas, and lobelias, are grown in pits; of these there are several long ranges, with lights eight feet long, some of the pits having one pipe only in front, others having no pipe at all. They are surfaced inside with coal-ashes, kept scrupulously clean and airy; and the result of the routine pursued is that in the month of May there is as fine a lot of plants as it is possible to imagine. I confess I have not seen this season the equal of the verbenas we found here; and as to other subjects, they were, as a rule, considerably better than the average of the stock met with in the best gardens. As most of the geraniums were in bloom, we were enabled to read them off pretty well as we walked round. The following are evidently favourites for this season:—Christine, Amy Hogg, Indian yellow, Dr. Lindley, Adonis, Stella, Cybister, Madame Vaucher, Waltham Seedling, Lucius, Black Dwarf, Beaton's Lady Cullum, Baron Ricasoli, Alexandra, Herald of Spring, Excellent, Madame Barré, Madame Rudersdorf, Merrimac, Rebecca, Gold Leaf, Cloth-of-Gold, Mrs. Pollock, Flower of Spring, Silver Chain, Flower of the Day, Bijou, and Manglesii. Traversing up and down these ranges of pits finished up our strength, and we made an end of our wanderings by compulsion of fatigue, and not by choice. Before we parted we came to the conclusion that we, the people of England, were gratified, delighted, satisfied, in some respects a little astonished, at what we had seen; that we had no objection to the extension of the ornamental slip at Albert Gate a few yards farther west, and that, in fact, an extension is necessary; that Mr. Cowper, who initiated all these improvements under the last Whig administration, had increased the already immense indebtedness of the inhabitants of the metropolis to him for elegant out-door recreations; and that, in respect of outlay from the public purse for the embellishment of this part of London, Mr. Mann is the man for our money. S. H.

BRITISH FERNS IN POTS.

I shall be speaking in strict accordance with the truth when I say that there are amongst the British Ferns some species which not only equal but entirely surpass, in point of beauty, some of our best exotics, when grown in-doors, and subjected to pot-culture. In saying this, I do not for a moment feel desirous to be understood as speaking in any way depreciatingly of the latter; for I am fully sensible of the many forms of beauty which they exhibit. One serious disadvantage to the exotics is this—everybody has not the means to give them the cultivation which is needful to bring them out to the best advantage; whilst, on the other hand, every one, whether peer or peasant, can, if they feel disposed, grow the Britishers with no more expense and trouble than the commonest plant which has ever been grown in a pot; and I feel certain that a few good British ferns in a cold house are far preferable to exotics having that half-starved appearance which they usually present when grown in a temperature too low for their requirements and well-doing. I am not going to advocate a rush to hedgerows, to dig up every *Lastrea filix mas* to be met with, and grow them in-doors, for that is scarcely desirable, although I have at the present time a fine plant of that kind, which I am prepared to back against some exotics receiving similar treatment; my object in this humble contribution is to draw attention to the better class of British ferns, for they really are much better for growing in unheated structures than kinds which require fire-heat; for the one will grow luxuriantly, while the other drags out a miserable existence for a few months, then disappears, to be replaced by others which will eventually share the same fate. I use well-drained pots, and equal parts fibry loam and peat, with a sprinkling of sand, for those kinds which I enumerate below, with the exception of the *Scolopendriums*, and I pot them in loam alone, for I find that it suits them best. I

am not going to attempt any technical account, but shall merely give a little common description, which can be understood by the uninitiated in the mysteries of botanical lore.

Few ferns are more beautiful than the airy and graceful *Athyrium filix femina*, or common lady fern; this is very fine when grown well, averaging two feet high in ordinary cultivation; but I have seen it over four feet in its native quarters. *A. f. f. Peildæ* grows about two feet high, with fronds from one to two inches wide. This is one of the best I have in my collection. *A. f. f. lacinata* is a very pretty dwarf plant, fronds from six inches to a foot long, but spread over the pot, so that the plant itself does not attain a height of over three or four inches. *A. f. f. multifidum* has the tips of the fronds beautifully tasselled. *A. f. f. crispum* is a pretty dwarf-growing plant, the fronds being crisped and tasselled similar to curled parsley. *Lastrea P. m. cristata* is a strong grower, the fronds being beautifully crested at all the points. *Lastrea dilatata coccinea* is also very good, and rather a strong grower; the common form of *L. dilatata* makes a handsome plant. Some of the *Polystichiums* are very good. *P. angulare proliferum* is a magnificent kind, with fronds about two feet long. I have a fine plant of *P. angulare* growing in-doors; but I am almost afraid to include it, on account of its being so common. Most of the *Scolopendriums* are very beautiful. *S. vulgare* looks very well in a pot, if grown to a large size. *S. v. endivefolium* is one of the best, similar to a botanical endive, but more curled. *S. v. crispum* has fronds two feet long, beautifully crisped like the frill of an old dame's cap-border. I should advise any one who intends forming a collection of British ferns to visit a good collection, as there are hundreds of really beautiful kinds. I give my plants a good shift in the spring, before they push up, which generally carries them through the season. Small plants are potted whenever they require. I shake a portion of the soil from the roots of large specimens, so as to give them a little fresh soil without increasing the size of the pot. The house in which they are grown should be well shaded, and the plants should never suffer from drought, or, on the other hand, get sodden.

VINDEX.

A HOLIDAY IN THE WEST.

PART III.—TO EXETER AND THE EXETER NURSERIES.

One of the most entertaining of railway rides is that from Tannton to Exeter; no tunnels, scarcely any cuttings, views of the country all the way, and such country! Hill and dale, high slopes, network of hedgerows, woods nesting in hollows, and woods climbing up precipices and rolling over mountain ranges. Far away, away, away, hills tower above hills, and on the far horizon rise higher still, and to the north-west the prospect terminates in faint indigo and purple peaks and piles; the mountains of South Wales—frowning mountains, but not unkind, for through the hazy distance they seem to whisper while they frown, "Come hither." Every few minutes the scene changes: you glide into woods, and through them, and out of them; you whisk past green corn-fields that stretch out flat and broad, and terminate abruptly at the feet of bright red slopes where the earth is hare; and next you plunge into the midst of picturesque villages surrounded by green meadows, and all the meadows filled with the neat red Devon cattle that take their colour from the red earth, as Adam took his name from it. Endless variety; no! variety almost to satiety, but not endless, for the journey ends where town and country mix beside the Exe; and the first view of Exeter, from St. David's station, is a series of most romantic slopes on the ridges of which are the neat cottages and villas—a poetic preface to a most prosy book; for Exeter, of all the cities in the land, is the most commonplace and prosy in which a human soul can suffer *ennui*. It is well worth enduring the tameness of the city for the sake of the journey there, because you cannot be kept prisoner, and, in fact, it would be an advantage if you were imprisoned in the Cathedral or the Guildhall; for the first is grand and solemn, and increases in beauty with every fresh observation; and the Guildhall has such a picturesque portico that, in passing under it to your cell, you would indulge the thought that Time had reversed his flight to give you a taste of the realities of mediævalism. Yes; Exeter has mean streets, tame churches; there is neither the hurry of trade nor the quiet of gentility to arrest the attention of the stranger; hut, like some of the prosy characters we meet with daily, it improves upon acquaintance, and is after all not so bad as it seems. We visited the cathedral several times during the four days that we were hovering in and about the city. The learned lady who described the interior made us deeply sensible of the peculiarity of the minstrel's gallery and the bishop's throne, of the beauty of the screen and the intricate sculpture of certain of the chapels, and we received all her gabble and female verger verbosity with the attention and devotion of earnest students listening to a Carlyle or a Ruskin. When the tale was told out, we went about in silence, and drank to the full from the fountain of everlasting beauty which has sent many a sparkling rill through this noble pile. The clustered columns, the windows, the vaulted roof, the large east window,—what harmony is there in the combination of these primal elements, and how they all appeal as with one voice to heart and mind to claim respect for the temple of the Lord! The screen, so highly praised, so proudly cherished, so curiously adorned with painted panels, is an abomination, for it mars the glory of a grand architectural perspective, and has but little beauty in itself. A lesson there for landscape gardeners—for all, indeed, to whom true art is precious. It matters not how rare, or costly, or truly beautiful an object may be, it becomes a nuisance when out of place, and like a rockery in the centre of an avenue, to interrupt the line of vision, is this hideous screen, which breaks a grand vista into two parts, and defames the dead designer by shamelessly cutting up his work. I dare not attempt to describe anything; I have no faculty in the guide-book line, and I shall quit the cathedral by observing that the west front is overwhelming in its

grandeur, yet the design is simple even to severity, and is perhaps as purely Gothic as anything of the kind in England. There are three stories and a basement screen, occupied throughout with canopied niches, in every one of which is a figure. From the corner of the little street (don't remember its name) which conducts you from close beside the door of the Globe Hotel into the High Street you have a side view of the whole of this west front, and to enjoy that for ten minutes will amply repay any lover of what is true and good in art for the whole of the journey from London to Exeter and back. This would probably be the finest cathedral in England were it surmounted by some central tower of altitude sufficient to redeem the exterior from the heavy tone that prevails throughout.

It is no mystery that Exeter is all prose; this is the proper transition from the poetry with which it is surrounded. After sweets bitters are pleasant. No doubt the people of Exeter study the prosaic as an antidote to the intoxicating tendencies of the beauties of the country in the midst of which their dull city is situated. Getting away from the trading part, where there appears to be prosperity without trade, we can find in any direction beautiful walks and drives. Wherever the river Exe appears the scenery is beautiful; wherever we see bits of the old city-wall, with ferns peeping out from amongst the stones, and great sheets of ivy hanging over like banners, and dandelions and hawkweeds flowering in the hillocks, and patches of germander speedwell (*Veronica chamædrys*) making hillocks of heavenly blue at the base, we feel the influence of old times upon us, and spring out of prose into poetry with exceeding joy. And the mention of this wild weed reminds me that we saw so much of it on the railway banks on the way to Exeter, that, except that the rattle of the train kept us fully undeceived, we might have thought we were sailing through the heavenly azure. I, indeed, being too deeply involved in a mere material inspiration, suggested to Confidante that if we were to expect any kind of flowers in heaven, I should sooner expect a spiritual reproduction of the germander speedwell than of any other flower I know, with the sole exception of the sylvan Forget-me-not. I was superbly put down for this profanity, and shall not venture such an observation (in the same quarter) again. There are two "hays" in Exeter. What the deuce is a hay or an hay? Is it a dancing green or a green for dancing? Perhaps the Saxon hæz or *haye*, a forest fenced in, or an enclosure kept for the pleasure of the town. The "Northern hay" lies high and dry, breezy, romantic—grand old elm-trees—glorious views. The "Southern hay" is the Finsbury Square of Exeter, green and semi-rural, and crammed to suffocation with doctors, lawyers, and agents for life offices, as if life must be in need of assurance where doctors and lawyers abound. There is no insurance for peace of mind, and yet one might be happy, perhaps, even in the Southern hay, for it is very quiet, has a nice garden and some big trees, and, as respects its inhabitants, might no doubt be described in language that a parish beadle used in my presence, and without awe, when I gave him a voting paper in a neat envelope. He actually called it "gallus genteel."

There are not many nurseries in Exeter, though in the horticultural world it is the most renowned city in the land, save and except the city of cities, where the wise directors of human affairs do mostly congregate. Speak of Exeter to a lover of plants, and he will ejaculate as chorus, "Messrs. Veitch and Sons." There is no such firm there now; the extreme dull prose of the city drove them away. They made their exit from the Exe, and came to the margin of the nobler Thames, to grow, blow, and show in the midst of money. But the name of Veitch lives in Exeter still, and before we quit the city we shall call and see the last of the Mohicans.

Messrs. Lucombe, Pince, and Co. have not toiled in vain to make Exeter horticulturally respectable. There is not a nursery in the British islands better entitled to our respect for the way of doing business, and the quantity of the stuff always to be found on sale. Our visit there was one of the best entertainments in the programme; for though the rain poured down every few minutes, Mr. Pince and self went about amongst the trees without discomposure or inconvenience; and when we all met at the festive board, and tasted Exeter hospitality, we really forgot it had been a pouring wet day and as cold as mid-winter; for it was now pouring wet in quite another sense, and warm as July, and the song most proper to the occasion was "Happy Land."

In the walk round, Mr. Pince took me first to his private pear garden, on one side of which is his own private vineyard. This is a walled-in enclosure crowded with pyramid pear-trees, all at that time full of bloom, beautiful to see and delightfully fragrant. By the way, folks tell me it is a delusion for me to speak about the perfume of pear-tree blossom. Is it? I can tell the folks who say this of another delusion. Yes, it is a delusion for them to suppose that nature has given them noses. She has done no such thing; appendages they may have that deceive the world, but noses!—no, no, no. "Noses were made to smell with," said the wolf to Red Riding Hood, and those who have noses can tell you that pear-trees in bloom emit a subdued odour of *Cratægus oxyacantha*; or, in other words, their fragrance is that of the thorn, but less powerful. But shut up an orchard house for half an hour when there are a few pear-trees in bloom in it, and then enter suddenly. Better occupation than than cavilling with me about the alleged delusion.

To return: the pear-trees in this out-door fructarium are nearly all worked on pear-stocks. Mr. Pince, than whom, to speak in the way of Nicholas, there is not in the land a better judge of what is right and what wrong in fruit-culture, is a decided enemy to the quince-stock, and at the best regards it as a curiosity. If it be said that the quince is to be valued because of its dwarfing property, and its promotion of early fruitfulness, the reply in favour of the pear-stock must be that here the trees are sufficiently dwarfed and sufficiently fruitful; and to me it is quite a question if in any similar extent of ground devoted to pears there can be found a better lot for number, size, shape, and fruitfulness. Mr. Pince believes in root pruning and top pinching, and practises both; and the trees are models in respect of outline and regular distribution of the fruit. To enumerate the varieties is just impossible, for I made no note of them; but the Rev. Mr. Huish's seedlings were all pointed out to me, and amongst them the original trees in several instances. All were smothered with flowers, and I trust are by this time smothered with fruit.

In going through the houses I saw nothing of special note, but on every hand fine examples of the best stove and greenhouse plants. In the show house, *Acacia grandis* is a favourite for spring decoration, and is certainly one of the best when covered with its golden flowers. Some fine examples of *Epidendrum Stamfordianum* and *Brassavola Digbyana*; plenty of *Epaeris*, *Erica*, *Chorozema*, and *Eriostemon*; in fact, everything proper to the season and the place, including swarms of *Aucubas* covered with ripe berries, and palms and ferns innumerable. Lots of glass, bedding plants, stove plants,

pinus, vines, orchids, cool conservatory plants, everything that could be thought as likely to be seen in a nursery. Yet none of these things, or all of these things together, do not constitute the real glory of the Exeter nurseries. The hardy and nearly hardy subjects, the coniferous trees and the cool greenhouse shrubs, are the pink and prime, and those on which Mr. Pince bestows the chiefest of his hopes and cares. Unrivalled collection! where and how shall we match it for specimens in the fullest perfection of their proper beauty? If a sensible echo were to reply to the question, the answer would be, "Nowhere!"

Where shall we begin? Here, among the houses? Good. Well, here among the houses is a new dipping tank, in Portland cement, with a rockery surrounding it, and in the rockery superb clumps of the creamy variegated *Euonymus radicans*, as bright as if but just created. Clumps also of several other of the best of the variegated Japanese plants. On the rear wall of one of the houses *Berberidopsis corallina*, a superb climber, as fresh and bright as if winter in these parts were unknown; close beside it a very large plant of the splendidly coloured *Euonymus latifolia aurca*, which is a great improvement on the old yellow-leaved *E. Japonica*. I have seen this new *Euonymus* almost everywhere, and it is one of our best plunging plants at Stoke Newington, but in no instance have seen it equal to the plant now under notice, which was spread out over quite a square yard of space, and had superb glossy leaves richly variegated. The new varieties of *Eleagnus reflexa* and *angustifolia*, of *Eurya argophylla* and *illicifolia*, of the holly-like *Osmanthus illicifolius*, the small-leaved *Ilex Fortunei*, with many other interesting and beautiful subjects in the same border, and all of them unhurt. A great batch of *Skimmia Japonica* (the one first sold under this name, and which is now *S. Reevesii*, or something else) covered with bunches of white fragrant flowers. This is invaluable at Stoke Newington for its neat growth and red berries, but we never get such growth as I observed here; it is the moist mild atmosphere that makes them at Exeter as free to grow, and nearly the same in habit, as *Rhododendron ciliatum*. Presently we find our way into houses full of such things, and *Aucubas* without end. Keeping a sharp eye for things new or strange, I at last light upon *Ligustrum coriaccum*, a shrub with elliptic, blunt, deep green leathery leaves. When this grows to some size, it will be one of the handsomest evergreens known.

Mr. Pince had talked several times of his rockery, and I was impatient to see it. In due time we found our way there. I shall not soon forget it, nor would you, good reader, if you have any taste in such things. One of our best contributors, who has travelled more than most of us, has averred in these pages that there is but one garden rockery in Britain worth seeing, and that is in the nursery of Messrs. Backhouse at York. I doubt, by this utterance, if he has seen the rockery at Messrs. Lucombe and Pince's. You enter by a winding walk into the very midst of rocks; they hem you in, they arch over your head, they open wide and display between their jaws grim knolls and gigantic blocks; they close again, and the path winds this way, that way, every way, now through a cave, now through a hollow, now over a hillock—endless variety, and on every hand a change in the style of planting and of the subjects employed. I saw here great clumps of double-flowering periwinkle, and of blue, white, and red periwinkle; clumps of *Aubrietia*, *Berberis*, *Forget-me-not*, and a thousand other gay flowering subjects; but the principal furniture throughout consisted of coniferous trees of the choicest kinds, and such as are especially adapted for rockeries. I shall enumerate a few of the subjects that I particularly noticed, as I can call them to mind, irrespective of their botanical relationships. *Berberis stenophylla*, when in flower a beautiful shrub, and admirably adapted for sprawling over great blocks. *Berberis Japonica*, *B. Darwinii*, *B. empetrifolia*, and indeed every variety and species of *Berberis* known, and a vast number of hybrids raised here, and wanting names, and well deserving them. One I noticed as especially good for the shrubbery; it is the result of a cross between *B. fascicularis* and *B. aquifolium*. *Cotonaster microphylla*, *C. thymifolia*, *C. nummularia*, *C. rupestris*, *C. acuminata*, and *C. luxifolia* in plenty and beautiful. I observed a *cotonæaster* with yellow berries that I should like to know more about. The variegated and the green-leaved varieties of *Arundo donax* have been thriving in this rockery for several years past, and no winter frost has hurt them; the snug shelter of this peculiarly sheltered nook no doubt was the saving of them during the winter just ended, for if they had been in open exposed quarters, I believe they must have been cut down to the ground, if not killed. They are in clumps six to ten feet through, and the old canes are 10 feet high; we cannot dream of such vegetation in the keen air of the East Angles. All the species of *Ruscus* are to be found here scattered about; amongst them one called *R. hypoglossum*, which produces in the centre of the leaf another leaf, a tongue-shaped leaf: the large leaf we may call a flattened or winged stem, and the little leaf is a true leaf produced upon it. This is a handsome plant. Of course our native "butcher's broom" is here, and the true Alexandrian laurel, which is the most beautiful of the *Ruscus* tribe. *Arundinaria fulcata* is a grand grass here, and quite hardy, and of course the *Pampas* is not wanting; but I do not remember to have seen the splendid glaucous-leaved *Elymus arenaria*, one of the most distinct of all for the sunny parts of a rockery, and needing only a spoonful of grit to live upon. Several species of *Cistus*; but one can make nothing of them in the month of April. I forgot to look for *Desfontania spinosa*, but I dare say it is here, and as hardy as a holly, though with the Londoners it is less hardy than a camellia. All the good species and varieties of ivies, in fact, a fine collection; so also of *Hypericum*, *Erica*, *Rhamnus*, and *Spiræa*, but it was no time to criticise such things. But the true glory of the rockery all through was to be found in the coniferous trees, with which it abounds. Here, for example, is *Dacrydium cupressinum*, 10 feet high, a tree made of green whippers, and in outline closely approximating to that of a sugar-loaf. I thought I knew something of *Cephalotaxus Drupacea*, *C. Fortunei*, and *C. Harringtonii*, before I went to Exeter; but the fact is I knew nothing at all of their splendour, when allowed for several years to grow in their own way, in a moist warm climate, until they attain the size of a rum puncheon, and broke into flower all over, as if hung with tassels of yellowish silk. Very few of us would expect to find *Picea nobilis*, *P. nordmanniana*, *P. amabilis*, and *P. pinsapo*, in any plenty in a rockery; but here they are, and fine examples too, sitting grandly in the midst of their miniature mountains, and showing their superb forms and colours with increased richness by contrast with the rock. *Cypripedium* in abundance, and of course *C. Lawsoniana* amongst them; *C. M'Nabiana*, *C. macrocarpa*, and *C. torulosa* also; and the transition from these to the unsurpassable *Thujaopsis dolabrata*, *Thuja pendula*, *Thuja gigantea*, the golden varieties of *Thuja (Biota) orientalis*, and the golden and silver leaved varieties of *Taxus*, cannot be out of taste. *Retinospora ericoides* is one of the prettiest of rockery trees, and here it is perfect.

R. obtusa and *R. pisifera* and *R. squarrosa* are hardy here, but in the east of England what are they? Echo, having recovered herself, replies, "What are they?" I have just taken a look at some of the first-named species in my garden, and I find them dead on the north side, and growing freely on the south side. Shall we blame the trees or the climate? Echo answers, "The climate!" No doubt about it at all; this is a horrid climate. Amongst the curiosities of this rockery are several examples of those conifers that may be said not to grow at all. Here, for example, is *Abies alba nana*, as old as Methuselah, and not yet taller than a quarter loaf. Still more diminutive is *Abies excelsa pygmaea*, a variety of the tallest of the spruces, which attains at the utmost the height of fifteen inches, but making ample amends by spreading over the ground like a mossy cushion. Many more such; but we must quit the rockery, for "life is short and time is fleeting," and we have not really got into the nursery yet.

On the way to the pinetum quarters we pass through the camellia house. It is a fine span-roofed structure, 200 feet in length, and about 30 feet wide, 20 feet high at the ridge. The trees look well, but are out of bloom, and we take Mr. Pince's word for it that they have been magnificent, and by the free growth they are making we conclude they will be magnificent again. Passing a sort of extensive shop-window, without any name or announcement upon it, I peeped in and found it was not a shop window, but a make-shift sort of glass wall for the shelter of a great lime-tree—not, of course, a Tilia, but the Lime that furnishes "lime-juice" for the navy, *Citrus limetta*. This tree covers about 150 square feet of wall, and is protected by a glass frame, through the base of which passes one return pipe, which is sufficient in winter just to keep out frost, or perhaps barely do so. The tree is in perfect health, and we brought away with us a few ripe fruits, fresh gathered, and from that day to this (a period of seven weeks) neither of us has been in the least degree afflicted with scurvy.

Now for the big quarters and the big trees. This is a tremendous business, and I shall somewhat shirk it, for fear of lengthening out the story.

On our way we pass a sort of tent or tiffany house, within which are some potted trees of exquisite beauty. Amongst these a perfect pair of variegated *Thuopsis dolabrata*, which surely cannot be surpassed in beauty by any other tree in the whole world. It grows here as if the tree and the climate were designed for each other, but it happens to be one of the hardest trees known. It is at present, whether green or variegated, both scarce and dear, but as to its intrinsic value it is worth any money, and it is almost a rebuke to Mammon that money will actually buy it. Presently we find ourselves amongst Wellingtonias, Araucarias, Cedars, Pinuses, and others of the princes of the mountains. It is a very grand sight to see thousands of gigantic specimens of such things in perfect health and wondrous beauty; the very formality of the nursery rows adds to the interest and effect, and the knowledge that all these great trees are periodically lifted, and can be planted any day in the year—except, perhaps, between the 10th of May and the 31st of July—gives the idea of a common property in them, for they are anybody's who can pay the price. When we admire a tree in a private garden, we know pretty well that we cannot become possessed of it for love or money; and if we could, the operation of removal would probably kill it; but all these trees are ready for distribution to the uttermost parts of the earth; there is just the formality of purchase to go through, and they are all yours, reader; ay, or any other man's. Of course, there are little trees as well as big ones, millions of little ones, but we cannot see them in the presence of the giants. Here, for example, are two Wellingtonias side by side, perfect pyramids, not a gap anywhere in their furniture that would admit one's hand, the lower branches lying on the ground like a luxurious fringe, all the rest contracting regularly till the trees terminate in sharp points. The height of this pair is 21 feet, and the price of the pair is £50. I might go on in this style, and if I said all I should like to say, some jackass would be sure to write an insulting letter and ask me how much I had been paid for the puff. But not for that reason, but to keep these sketches within some sort of limits, I will hurry on. *Cephalotaxus Fortunei*, 10 feet high, in bloom, a splendid object. *Cephalotaxus Drupacea* is handsomer than the last, and a grand tree for a choice garden, quite a proper sort of tree too for a terrace or Italian garden. *Pinus parviflora* is a pretty glaucous-leaved tree, bearing myriads of small brownish cones. *Wellingtonia gigantea stricta* is a seminal variety raised here; its peculiarity is a rigid habit of growth, the leaves being of a thicker texture than the species, and very dense in their arrangement; it is rather glaucous, but not enough so to be valued as a variety. *Picea pinsapo*, in sublime proportions, almost cylindrical in shape, and delightful when showing its new growth. *Pinus insignis* is rather tender here, as everywhere else when young, but when it gets up, and has made a lot of hard wood, it is as hardy as any *Pinus* known. Right opposite to Mr. Pince's residence there stand a pair of *Insignis*, about 30 feet high, noble trees, with not a mark of the past winter upon them. *Deodars* we pass by; the reader will guess that there are plenty of them, and that very many of them are grand in size and proportions. The last thing I shall relate is that I saw a tree of *Cupressus Lawsoniana* covered with both male and female flowers, a rare sight, and one to be remembered. If this *Cupressus* be examined now, in almost any garden, it will be found freely sprinkled with green nearly globular cones. The male flowers are produced at the tips of the branchlets, and consist of red stamens enclosed in purplish scales. When these are produced in plenty, as in the tree I am now calling to mind, the effect is at once peculiar and pleasing.

I must now beg pardon; I intended to finish, but there are two subjects yet remaining for a word each. I found a pretty crah in bloom, a good companion tree to *Pyrus spectabilis*; the name of it is *Malus floribunda*. Book it as one of the best things ever heard of for garden or shrubbery, or to pot for the conservatory. Little trees two to three feet high were smothered with large rose-like flowers of the most lively pink colour. Lastly, I saw, still hanging on the original vine, a bunch of *Mrs. Pince's Black Muscat Grape*, and I tasted a berry and found it to be delicious. When the bunch was ripened I don't know, but suppose it to have been the 20th of September, and the probability is it was ripened considerably earlier than that; yet, in that case, the bunch had been hanging seven months, and was now perfectly clean, and only a little shrivelled. It is one of the most peculiar vines in cultivation, the wood being of a purple colour, and the leaves a peculiar bluish-green. As to its value, there can be no question that for flavour at any time when ripe it is equal to any grape known in its class, and far better than any in keeping properties. Mr. Pince begged me not to make notes, and so deeper than did ever plummet sound I drowned my book, and there may be a little want of arrangement in the foregoing. If such be observable, you must blame him, not me. I can remember a great many tunes, but without my hook I am apt, like a circus clown, to play them all together. S. 11.

ORMSON'S PARADIGM HOTHOUSES.

We lately offered some practical hints on the improvement of soils and situations not naturally favourable for the production of early crops; and it is a matter of the utmost importance to most families that their supply of both fruits and vegetables should not only be early and sufficient, but also that it should be uninterrupted and certain at the season each variety is required. Now in order to ensure this in so uncertain a climate as that of the United Kingdom, many and various methods of protection are resorted to by gardeners, and many schemes invented by scientific horticulturists, in order to modify natural conditions of soil and climate, and secure suitable localities for the thousands of exotic subjects, mostly natives of milder climes, that are introduced to our gardens, by which the enjoyments of life are greatly increased, and, in the present luxurious and refined state of society, are looked upon as real necessities. What would my Lord of Belgravia think if his

housekeeper were able at this season of the year to offer him a dish of cabbage, and last year's potatoes only, with his lamb, &c.; or oranges and nuts with his wine; or my lady, to see her boudoir garnished with lilacs and daffodils? Beautiful as they are, they would fall far short of the dignity and exquisitely refined beauty and fragrance she is accustomed to enjoy in the orchids and other choice exotic forms, reared for her enjoyment in stoves and greenhouses. All these things are become necessities in proportion to the means of each individual to procure them, and are as sure an evidence of growing refinement in society at large as the removal of the glass-duty, which fettered the skill and clogged the energies of horticulturists, was a mark of progress in political economy, and a measure worthy to place its promoters in the foremost rank of human benefactors; for without a free and unrestricted use of this material gardening could not possibly have attained to the importance it has done. What can be done with it where expense is no object has already been shown in the people's Crystal Palace, the Palm

House at Kew, &c. What can be done with it when means are limited has been shown in some measure by Mr. Rivers, and others, in devices for the protection of choice fruits, &c., at a cheap rate, many of which possess considerable merit, though not always so in every particular; for that which is produced at a low rate of cost in the first instance frequently turns out anything but economical in the end. This failing, however, so far as stoves and hothouses are concerned, seems now to have been overcome, for not only may a cheap greenhouse be obtained in point of cost, but also cheap in point of quality; and gentlemen may actually surround their acres of kitchen garden with glass fruit-houses at little more cost than they can build a good garden wall. What the result of such a movement will be remains to be seen; but we confidently anticipate that choice peaches and nectarines will by and by be as freely enjoyed by every school-boy as oranges are now, and that every family that hitherto have been content with raisins for dessert will,

instead, be enabled to enjoy fine home-grown Hamburgh and Alicante grapes, besides which thousands who have never done more than hear of the delicacy and luscious richness of "Coe's" and other late hanging plums, or known figs in the state they are sold at the grocers, have yet a treat in store, and we confidently anticipate that fruit-houses as boundary fences to gardens, instead of brick walls, are destined to work a revolution in our fruit supplies. The anticipation of such a blissful state of things has given wings to our pen, and we find our space exhausted before half has been said that might be said on this subject. We cannot, however, conclude without referring our readers to an exhibition of drawings and specimens of cheap and serviceable fruit and plant-houses, which, as their title imply, are really examples of excellence and simplicity. These are to be seen in the eastern arcade of the Royal Horticultural Society's Gardens, South Kensington. Mr. Ormson, the well known horticultural builder, has made public these examples of his skill and enterprise in the expectation that their cheapness and excellence will be generally appreciated, and we doubt not but he will be rewarded by a liberal patronage.

The "Paradigm Hothouses" (*Paradigma*, an example, Lat.) are made so that all the parts may be quickly separated, the several frames of which the houses consist being bolted together, and there are no rafters in the ordinary sense of the term. The whole of the mechanism is prepared by machinery, which greatly reduces the cost, and ensures greater accuracy of fitting than the best hand-work. The ventilation is effected by side shutters, which exclude cutting draughts of wind, and admit of netting being placed, if desirable, to keep out insects, and by a continuous ventilator at the ridge, which can be opened and shut at pleasure. These houses merit the attention especially of persons who are forbidden by their means to indulge in costly structures, but who nevertheless would rather be without glass than have it in an unsightly or inefficient form. W. H. H.

DECORATIVE GARDENING.

At a time when every one's attention is directed to the replenishing of flower borders, it may be well to throw out a few suggestive hints bearing upon the mode or modes of planting and arrangement that have been practised for the last few years. Much has been said and written against the modern system of hedding out, because of the general sameness, the want of variety that characterizes many of the designs, the incongruity of the picture as representing a few shades of gaudy colours placed in diametrical opposition to the principles of colour arrangement, and scarcely less confused than a variety on the palette of the artist. To this catalogue of exceptions must be added the enormous expenditure of time, which means money, entailed in providing, propagating, preserving, propagating again, and nursing, before the hundreds or the thousands of plants can be turned out to do duty during the gay season. Such a formidable bill of exceptions appears at first sight to be almost overwhelming; and one might be glad to stumble upon any loophole of escape to seek for a simpler and less expensive method. Were it simply a question of pounds, shillings, and pence, there would be no difficulty in summarily dealing with it, for it is as clear as noon-day to any and all who are capable of giving the subject the least consideration that a mixed arrangement of herbaceous plants and annuals will not cost one tithe of the money, if all were reckoned up, that must be placed against the representatives of hedding-out.

Singularly enough, amid all the hue-and-cry, no one appears to be completely satisfied with the herbaceous border and the way it was managed. Ambition prompts numbers of all grades, very differently situated as to length of purse, and consequently size of residence and extent of domain, from the peer to the peasant, to aim at a higher style of elegance, and to seek and cater for a more imposing display. Why, it may be asked, nibble at little haits, and become supercilious and crotchety over the merits of a system which ninety-nine gardeners out of every hundred do not properly understand—that is to say, if we are to judge from actual results? Many good and clever men, no doubt, are crippled from insufficiency of resources, and often attempt far too much to be anything like successful, and possibly forget or are unable to perform certain duties which, under the circumstances, it might have been wiser to attend to. This much must be said, that a thorough intelligent (scientific, if you like) appreciation and application of the principles of hedding-out to surrounding or collateral objects is one of the grandest feats in gardening practice. Because it is so—and many lamentably fail, a few are apathetic, and some stubborn—we have a wail of lamentation against geraniums, calceolarias, and verbenas, as if these and a few others constituted the staple of high-class decorative gardening! One can understand objection being taken to expense, to the excessive formality which some drift into in their mode of arrangement, and to some other knick-knacks which it is unnecessary here to specify; but these mainly point to matters of detail, which are capable of being corrected. The great object aimed at from different points of view is *variety*, but variety is not incompatible with symmetry, as Montesquieu avers; and there must be symmetry in flower garden arrangements, be the space limited or extensive; but it is possible, verily probable, that the variety, so much lauded in connexion with the mixed borders, may degenerate into confusion, and then we have neither the congruity, order, symmetry, or proportion of even a very so-so arranged garden on the hedding-out principle. On that account, if upon no other, we must separate the two systems. Give each of them a place—the one on the margin of a landscape, facing a waving and undulating line of frutescent and arborescent vegetation, the other in juxtaposition to any architectural section, or what is known in gardening phraseology as the dress portion of a landscape. By so doing, winter and spring decoration need not be ignored, nor herbaceous plants or annuals blotted out of the gardener's plant vocabulary.

A few simple things of elegant outline should be improvised, and such things as suggest themselves to us can be gathered up either from stock in hand or bought at very little cost. Uniformity of outline, in so far as uni-

formity is formal and flat, is probably even a greater error than insufficient variety in the make-up of a parterre. By the introduction of a few of the more elegant forms of Coniferae, such as *Cupressus Lawsoniana*, *C. Nutkaensis*, *Thuja dolabrata*, *Thuja Lobbi*, &c., we would have both variety and diversity of contour. One can easily understand how very much more effective a design would become if a little more attention were given in that direction. Even the common Irish yew and the golden one would be very effective subjects. Then might be called in various plants with ornamental leaves, such as the variegated *Negundo fraxinifolia*, and the many other types of hardy forest trees which would do duty most effectively, and embellish a design in their younger stages. Many of them might require to be sacrificed after a time, but first cost is a mere bagatelle, much less than many pelargoniums. Look, again, at plants of a graceful habit, after the manner of *Humea elegans*, than which there is not a more graceful or appropriate subject, only it requires considerable space to winter. The cut-leaved birch would even make a famous fellow, trimmed with the knife; and there are many elegant grasses that could be well improvised, such as the variegated forms of *Poa trivialis* and *Arundo donax*, to say nothing of the more gigantic Pampas and the still more gigantic *Arundo conspicua*, the plumes of which appear in the distance like great white ostrich feathers. We have yuccas hardy enough to stand any amount of fatigue; and would not the *Robinia pseudo-acacia*, the oak-leaved *Hydrangea*, the many varieties of hollies, and the splendid purple Japan maple, add to the interest and beauty of any formal arrangement? Although we have seen the *Arundo* and the Japanese maple in splendid condition at Messrs. Veitch's nursery, where they had proved quite hardy, they will be found too tender in many localities; but they are such fine subjects as to merit a little extra care, in the way of protection, during winter.

Once fairly initiated in the practice of selection of so many interesting and diverse forms to reinforce the hedding-out system, and it is bound to become popular; because we can have variety, form, contrast, and occasionally, "if weather permits," unquestionable grandeur. Let the reader profit by the hints and advice proffered, for now is the time to act, while the hedding plants are being transferred to their summer quarters.—*The Farmer*.

Calendar.

WORK FOR WEEK COMMENCING JUNE 8.

Kitchen Garden and Frame Ground.

ASPARAGUS to be cut as required when it is well above the surface. We gave a note on this subject three weeks ago. Take care that in cutting a shoot you do not spoil one just rising.

BROAD BEANS to be sown again if a late supply is at all likely to be wanted. Top those in flower as soon as a reasonable amount of bloom is expanded; the small early sorts, such as Hangdown, to be topped when about eighteen inches high, and the strong growers, such as Longpod and Windsor, at two and a half to three feet high. But the height much depends upon the way they are grown. When in close rows they run up tall; when in single rows, far apart, they are much shorter and better.

BROCCOLI coming forward in seed-pans must now be pricked out on well-manured beds, four inches apart, and when they touch each other will be a good time to plant them out for flowering. Sow Walcheren and whatever other sorts are to be sown to stand the winter.

WINTER GREENS of all kinds to be planted out as occasions offer; a few of the forwardest plants of Brussels sprouts should be put out where they are to remain in deeply trenched and well-manured ground to furnish an early supply of hutons, as they are everywhere prized when the summer vegetables are over.

CUCUMBERS ON RIDGES may now have the hand-lights or other protection removed, so as to benefit by the night dews and showers. It is not advisable to stop them, but a little pegging to cover the beds regularly is beneficial, as creating a greater extent of bearing surface.

CUCUMBERS IN FRAMES require an abundance of water, both over the foliage and at the root. Put a few cans of water in the pit or in a warm house early in the day, to have it warm and soft for use in the afternoon; then use it and shut up, and if the beds are extra warm give a little air an hour afterwards.

LETTUCE to be sown now where they are to remain. This is a golden rule to prevent bolting when the weather becomes torrid. Wheeler's Tom Thumb and Paris cos are two of the best sorts to sow now for successional use.

PEAS do better without water than with it, if they are in trenches well manured before the seeds were sown. Sow a few first and second early sorts, giving preference to the wrinkled varieties if possible.

TURNIPS.—As there will soon be a demand for these, it will be well to sow a small breadth in some odd place, so as to secure a few small bulbs in advance of the ordinary autumn supplies. Take especial care to break up and manure the ground first, or the crop will come to nothing.

VEGETABLE MARROW.—During warm showers is a good time to plant these out. But they ought first to be somewhat hardened by placing the plants in a sheltered spot for a week. To take them from warm cucumber pits or propagating houses, and plant them direct, is bad practice.

CELERY to have an abundant supply of water if the ground is dry, as slow growth is ruin to it, and may cause half the crop to bolt. Continue to plant out, using abundance of rotten dung well worked into the soil of the trenches.

LEEKS to be transplanted from the seed-bed to very rich ground, and to be earthed up as they grow, to blanch the neck of the bulb. The frequent use of sewage water will swell them to a great size, and with improved quality.

Sow lettuce for succession, broad beans, wrinkled marrow, Emperor, and Advance peas, radishes, scarlet runners, turnips, Early York, East Ham, and Shilling's Grotto cabbage, a few Rosette coleworts, and Walcheren broccoli.

SHOWERY WEATHER brings as much work as drought and sunshine. During a dry heat, ply the hoe to kill weeds, and promote a heavy deposition of dew on the newly broken ground, a considerable quantity of which will be conveyed to the roots of the plants. During showers, plant out whatever the ground is ready for, and whatever is fit for planting. It may make all

the difference between a good crop and no crop at all to seize the right moment for planting out, influence of warmth and wet being so eminently favourable to every kind of vegetation in a youthful state.

Flower Garden.

PINKS must be supported by neat stakes to keep the blooms from being spilt by rain and wind. The best way to propagate is by pipings, and now is a good time to secure plenty of them.

GRASS LAWNS newly made must not be so closely mown as old turf. But mowing must be performed with regularity, or it is impossible to obtain a uniform velvety green surface. To mow close a well-established turf is to encourage the fine grasses, and kill out the coarse kinds.

ANNUALS.—This week or next is a good time to sow any of the quick-growing annuals for autumn display. The blue Nemophila blooms beautifully if sown at the end of June; better by far than from spring sowings. Balsams, Asters, and Stocks to be planted out where they are to flower. Sow Brompton and Queen Stocks.

BEDDERS to have every necessary attention to regulate the growth and display the bloom; peg Verbenas and other trailers as soon as they need it. If the ground is very dry, loosen the surface with the hoe between the plants, and if necessary to water, soak the ground well. Plants running away to leaf to have no water; and where Tropæolums grow rank, remove a few of the leaves, so as to make more room for the blossoms to be seen.

BORDER BULBS may be taken up as soon as the leaves are withered, and to ensure a perfect ripening lay them in clumps as taken up, without damage to the roots, in a shady place, with a sprinkling of earth over them. The practice of laying hyacinths and tulips in a broiling sun is one of the causes why so many are worthless the next season.

DAHLIAS to be tied up betimes, or sudden gusts of wind will tear away the best branches from the base. On hot dry soils mulching is needful, and will prevent need of watering, but in small gardens mulching attracts vermin, and had best not be practised. Those that want a little extra help had best have manure-water.

PROPAGATE at once Neapolitan Violets by dividing; Pansies, by cuttings and layers; Pinks, by pipings and cuttings—if the latter, dibble them into pans and cover with bell-glasses; put pipings in the open ground in a shady place; Chrysanthemums, by cuttings, for blooming under glass in pots; Roses, by cuttings and half-ripe wood; and any summer-flowering plants wanted for late blooms under glass; also Iberis sempervirens, the best of all spring flowers.

TRITOMA UVARIA and varieties require abundance of water now, especially if in pots. Lilioms the same; when throwing up their spikes they can scarcely have too much. Ixias and other Cape bulbs in flower need the same treatment; after flowering, lessen the supply, but allow free growth, that they may die down and ripen naturally, during which process let them go quite dry.

Fruit Garden and Orchard House.

RASPBERRIES are swelling their fruit, and if a few extra large samples are required, it is a good plan to thin the fruit on the canes, and give them two or three heavy soakings with manure-water. But for all ordinary supplies it is best to let them ripen as much fruit as they will. The ground amongst raspberries is now pretty well paved with seedling plants from berries that fell last year. Hoe them down; they only rob the fruiting ones of nourishment.

STRAWBERRY BEDS are showing a good crop, and the plants are generally in good health. The best of all materials wherewith to cover the ground to keep the fruit clean is cocoa-nut fibre refuse. In the place of this grass-mowings may be used, or clean straw or chaff.

BUSH AND PYRAMID FRUIT TREES are generally in better health than standards, because they get more attention; and as they are in a somewhat artificial state through close pinching and frequent lifting, they require extra attention. Shorten in at once all rambling growths; tie in espaliers while the wood is pliable, as, if they harden out of shape it will be difficult to train them hereafter. Keep down grub, fly, and American blight. The simplest remedy for the last-named pest is the Aphis Wash, made by the City Soap Company.

GRAPE-VINE MILDEW AND OIDIUM.—Some short time since Mr. Lazaris, proprietor of well-managed vineyards at Corinth, made a series of experiments in order to discover some cheap substitute for sulphur in the treatment of vines. The result was the discovery that any kind of fine earth may be used in lieu of sulphur, which, he says, acts medicinally and not chemically, and that any fine dry dust will serve the same purpose. The conclusions at which he arrived were stated in the following terms: 1st. The earth should be freed from sand and gravel, dried in the sun a few hours, pulverized very finely, and then sifted or bolted like sulphur. 2nd. That as common clay is easily prepared as above, and adheres well to the vines, it is preferable to other kinds of soil. 3rd. That the instruments generally used to apply the sulphur will serve for this also, at least for the first and second operation, but the third time, as the grapes have then some size, it is desirable to have them more abundantly powdered, yet it is possible here to use the same instrument used for sulphur. 4th. The powdering succeeds best when applied after sunrise, but while the grapes are still somewhat moist with dew. The following times are the best for the application: a. When the young shoots have scarcely attained the length of a span, before the grape is in flower. b. As soon as the flower has fallen, and the young grape entirely set. c. When these are of the same size as is thought sufficient in sulphuration. 5th. Independently of these, even when performed with care, it is necessary sometimes to make extra applications, as, for example, each time after a heavy rain, after waiting a day. 6th. The removal of a part of the leaves, as is usual, is advisable, if practised with moderation; otherwise, the vines deprived of leaves, the grapes may be scorched by the heat of the sun. 7th. If from any cause the first regular powdering has been omitted or neglected, it will be necessary to supply it by two others, with an interval between of eight or ten days. But it is indispensably necessary that it be done before the time of the second regular application. 8th. It is necessary always to perform the operation with the greatest care. It is well to have the workman followed by another, who again carefully examines the vines, and powders any that may have escaped. If after this disease reappears, it is proof that the operation has not been well done, and it is necessary to immediately repeat it with all the care that is bestowed when sulphur is used.

Greenhouse and Conservatory.

AZALEAS that were flowered early have now finished their growth, and may be put out to harden. Select for them a sheltered shady position,

and stand the pots on bricks or slates to prevent worms getting in. Cultivators differ in their opinions, and consequently in their practices, in regard to putting azaleas and camellias out of doors. Long and careful observation has convinced us that if they can be kept under glass the whole year round, it is far better than putting them out; but generally glass is of too much value to be so employed, and it is a matter of convenience to take these subjects into the open air, in order that the houses may be kept gay with other things. Azaleas not yet done growing, or only just pushing into growth, must be assisted with a gentle heat, and abundance of moisture, head and foot.

CALCEOLARIAS of the herbaceous class that are going out of bloom must be cut down if it is intended to keep any of them, as if they are allowed to produce seed they will probably die. When cut down give them a shift into larger pots, or plant them out on a spent hotbed, and take the lights off at night, that they may enjoy the dew. When they break freely, propagate with the help of gentle bottom-heat, and when you have enough of each securely rooted destroy the old stools. The most skilful cultivators, however, prefer to grow from seed, and all the fine collections shown of late years by Messrs. Dobson, Mr. James, and others, have been seedlings, though it has become the custom to name them as if they were grown from cuttings, and had a permanent place in the lists. It is rather early to sow seed yet, but a small pinch may be started by those who wish for bloom at the earliest possible date in 1868.

FUCHSIAS must be shaded, and must have abundance of water, and plenty of syringe.

ERICAS and kindred plants are better off in cold pits now, as it is next to impossible to give them air enough in any plant-house. Indeed, a heath-house should have removable lights, so that the heaths could be treated as peaches are in many places, the lights removed altogether during the summer months, and put on again in autumn.

KALOSANTHES require an abundance of water now, as do all succulents that are growing freely. Liquid manure will now do great things, and careful training must be practised if handsome specimens are wanted.

CINERARIA SEED to be sown in pans of light rich soil, with a sprinkling of very fine earth over. Lay over the pans pieces of glass, or damp moss or tiles, to prevent evaporation, but keep a watch that the plants are not blighted through keeping the covering on too long. Keep the pans in the shade till the plants are large enough to pot off, which will lessen the trouble of watering, and also the risk of loss either by damp or drought. Plant out named sorts to get offsets.

CAMELLIAS need air now night and day, and the swelling of the flower-buds should be the signal to cease watering over-head, which may cause the flower-buds to start into leaves, and spoil the next season's bloom. Plants that want a shift may have it now, but large shifts should never be practised.

LIQUID MANURE.—Any manurial matters can be, to a more or less extent, dissolved in water for the production of liquid manure, and the strength of the material used must regulate the quantity of water applied, and the nature of the plants to be fed with it. The following are generally useful mixtures: One part by weight of fresh cow-dung to six parts by weight of water; stir, and leave it some hours to settle; use only the clear liquid. The drainage from the stable and cow-house is a most valuable basis for liquid manure; add to it eight times its bulk of water. The brown liquid that flows from new dung-heaps is to be used in the same way. One part of fowl's dung to eight parts of water. One peck of fresh sheep's dung to thirty gallons of water. Sulphate of ammonia, half an ounce to every gallon of water. Guano, half an ounce to the gallon of water. The best of the prepared manures is "Standen's Gardener's Friend," sold by Barr and Sugden, and the best way to use it is to sprinkle it on the surface of the soil, that the watering may wash it down to the roots. In all cases it is best to give liquid manures weak, and especially at first. If it is intended to give a plant strong doses, a few weak ones should be given first to prepare it, but to be always weak is much safer and more beneficial in the end; for an overdose will cause the leaves to fall or to become blotched, and do other injuries that need not be enumerated. As a rule, liquid manure should only be given to plants in pots; it is a waste of labour and expense to liquid manure plants in the open ground.

HERBACEOUS CALCEOLARIAS.—These magnificent flowers have been admirably exhibited this season at the London shows by Messrs. Dobson, Mr. James, and others, and have won many new admirers. The best way to raise them is by seed, and good seed may be had of any respectable seed-man; but if you want seeds of Mr. James's saving, you must apply to Mr. B. S. Williams, Victoria Nursery, Holloway, for it. Suppose you have a pinch of good seed, the proper time to sow it is during the months of June and July. These plants are not easily grown; and, unless they are well done, they become a nuisance and a disgrace; for besides giving a poor bloom, they show a wretched foliage, and are alive all over and always with green-fly. So begin properly. Sow the seed in very light rich soil—say peat, leaf-mould, silver sand, and manure rotted to dust (three years old), equal parts. Prepare the seed-pan with a nice bed of small crocks to make perfect drainage; lay on the crocks a thin spread of moss, then fill up quite to the edge of the pan with the compost, well mixed and broken fine. Press it gently to a smooth surface, wet it thoroughly, and sow thin. Sprinkle just enough of fine peat-dust to cover the seed, and lay a thin coating of moss over. Place the pan where it will be warm, close, and shaded. A cucumber pit is a good place for it. The plants will soon appear, and the moss must be removed carefully. Keep them close and moist; they do not require much air, and as to water, they must never be soddened and never go dry. If they get dry, the aphid will appear immediately, and perhaps red-spider too. The best of all (and the cheapest) shading for seed-pans or plants during sunny hours is a newspaper gently laid over them, and of course to be removed as the day advances. As soon as there are a few plants large enough to take hold of, say with about three leaves besides the seed-leaves, begin to pot them. Take thumb pots first, put one small piece of brick the size of a walnut at the bottom, and fill up with the same mixture as was used in the seed pan, and into each of these pots plant one of the little hopefuls, water gently, and place them in a warm shady place, where there is not much air. If you do not keep them growing, the vermin will grow instead, and you will regret it. As soon as another lot can be taken out of the seed-pan, pot them, and so on till the pan is empty. By the way, the best method of lifting them out is with a bit of stick, or the sharp end of a wood tally. The after management consists in potting on as fast as they need it. After the end of August an intermediate house is the best place for them, or a shady cool part of a stove. They do well where Begonias grow

freely, and the same moist atmosphere will suit both. At the first shift out of thumb pots the compost should be light, silky loam, such as will crumble to dust between the fingers without soiling them; what we call "forest loam" on the north side of London is the best ever used for the purpose. Take two parts of this loam, one part good leaf-mould, one part fresh horse droppings, rather dry, and the straw all removed. Mix this together, and break the lumps, but do not sift it. Pot into 60's, then to 48 size, and so on, till you have them in eight or ten inch pots. But if done on a small scale, very nice plants may be flowered in pots of seven or eight inches width. Potting must be done at least once every three weeks all the autumn and winter, and about the middle of February you may consider the potting business at an end, and begin to think about flowers. At that time pick out the strongest plants, and remove from the stove to a warm greenhouse. In the first or second week in March take them to cold pits, and keep them rather closely shut if an east wind blow, but during those bursts of warm moist weather, with a west wind, which generally occur in March, the lights may be taken off for a few hours, and the plants may enjoy a slight wetting. As the season advances, and they acquire some degree of hardiness by this treatment, give them more air, and at last expose them fully, but always shade them from very strong sunshine. As a matter of course, they will all find their way to cold pits by this course of treatment. They will have been grown with the aid of heat, and flowered in a cool free air, and their appearance at least will repay you for all your pains. Vermin will occasionally appear, especially during September and February, even with the heat of treatment. To allow them to get ahead is to sacrifice the plants. Shut them up when their leaves are dry, and smoke them thoroughly with pure tobacco. Do not risk the use of any preparation of tobacco, unless it be "tobacco tissue," which consists of tobacco only, and is merely prepared by pressing, not with chemicals of any kind. I have not tried the aphid wash of the City Soap Company upon them, but have no doubt at all it would cleanse them thoroughly, and without harm. The way to do it would be to mix the wash, according to the directions that accompany it, with water, in a large tub or pan, and turn the plants upside down and dip them, keeping them in the mixture a few seconds, and then holding them above it to drain back before placing them on their feet again. Dipping wets every part of a plant, syringing does not. I say nothing about tying out and many other small matters, for the simple reason that every cultivator either knows what to do or will soon find it out. They may also be propagated from cuttings. This method of growing them has this advantage, that before you begin you know exactly what sort of flowers you will have, which is impossible with seedlings. The named kinds, which of course you would alone select from, are remarkably beautiful. The best time to take cuttings is immediately after flowering, and as soon as enough cuttings are obtained throw the old plants away, for they are useless, and should never be preserved except for some peculiar reason, and then it needs much care and skill to keep them in health. Short, plump, rather soft shoots make the best cuttings, and these root quickly in a mixture of half peat and half sand, on a gentle bottom heat, if kept close and shaded. When rooted, pot them on, and grow them to flowering size in precisely the same way as described above for seedlings. Cuttings may also be taken in February to make nice plants for a late summer bloom; and if a quantity of any particularly choice variety is wanted, cuttings should be put in whenever they can be got.

Forcing Pit.

PEACHES in the succession house will require the same care while stoning as trees in a similar stage in the early part of the season—that is to say, it will be well not to overload them with water at the root, or to syringe very freely. During the stoning period is a good time to thin the crop, especially at the time when they begin to swell a second time, as they are then thinning themselves freely, and the operator can see pretty well what he is about.

PINES must have abundance of atmospheric moisture now that the sun-heat is powerful, and the plants are in full vigour. The temperature may range from 90° to 100° safely if the paths are freely sprinkled, and ventilation is attended to. Shut up with a moderate sun-heat, and use the syringe immediately, not so much to fill the hearts of the plants with water as to moisten the plunging material. Pines requiring repotting must not be neglected, or they will start into fruit prematurely.

VINES in late houses must have the bunches thinned, and the laterals stopped; syringe to be used without stint, and air to be given freely. Ripe bunches in early houses required to be kept will be safer if the house is well aired and kept rather dry, and this will be better also for the vines.

Correspondence.

PROGNOSTICATION OF THE WEATHER.—There is no question but that some mode by which the probable weather for a week in advance may be arrived at, is a matter of great moment to agriculturists and gardeners, in fact, to any person having an out-door occupation. The best guide I have met with has been the seemingly senseless selection by the French General of the 4th, 5th, and 6th days of the moon, and which generally I have found to be a sure guide. The result of the month's observations you published showed how truly the weather followed the indications of the particular days; and I am inclined to think that if the winds of those days were taken into consideration, together with the actual results of the weather of those days, that an almost sure guide would be attained. As I have before said, there does not appear to be any reason for the selection of the particular days, and it seems almost absurd when one announces the reason by which the conclusion is arrived at, whether to carry that misery of most thinking men, an umbrella; for, nine times out of ten, any one who has anything else to think about is sure to forget that such a thing appertains to him, unless a pelting shower or drizzling rain gives him a gentle reminder; so if the indicated days serve no other purpose, they at least are likely to rid one of a bore. In chattering thus I shall forget my errand, which was to send you my sailor friend's indicator, which, for convenience, I have formed into a table, and being sent, you, as well as your readers, must take it for what it is worth, for I have no observations to back it up. I am content with the French general. By the way, I forgot to say that the sixth day of this moon being very fine, and the 4th and 5th more or less cold and rainy, that no indication by his mode could be arrived at for the weather of this month. Had the 6th day been in consonance with either the 4th or 5th days, I should long before now have regretted putting out my plants. My friends the swallows have

been a little deceptive this time. However, I have not suffered yet, and I have had the plants out since the 4th of May; and one night we had 6° of frost, which was Saturday morning, the 18th of May. I looked at the thermometer at half-past 4 a.m.; it stood at 26°; at half past 7 a.m., thermometer in same place, and untouched, it stood at 66°, a difference of 40°, but fortunately the ground was dry.

Table constructed upon Philosophical Principles, from the Attractions of the Sun and Moon, in their several positions respectively, and tested by many years' experience, has been found almost unfailling.

(SAILOR FRIEND *loquitur*: "The last moon and present have not at all obeyed the philosophical principles.")

The Quarters of the Moon commencing at the hours as under may be expected to be for the continuance of the quarter.	SUMMER.	WINTER.
12 o'clock noon, or between 12 and 2.	Very rainy.	Snow—rain.
2 to 4 afternoon.	Changeable.	Fair—mild.
4 to 6 evening.	Fair.	Fair.
6 to 8 "	Fair, if wind N.W., Rainy, if S. or S.W.	Fair and frosty if wind N. or N.E.
8 to 10 "	Ditto.	Ditto.
10 to 12 night.	Fair.	Fair and frosty.
12 to 2 morning.	Fair.	Hard frost, unless wind S.W. or S.
2 to 4 "	Cold, with frequent showers.	Snow and stormy.
4 to 6 "	Rain.	Ditto.
6 to 8 "	Wind and rain.	Stormy weather.
8 to 10 "	Changeable.	Cold rain, if wind be W.; snow if E.
10 to 12 "	Frequent showers.	Co'd, with high wind.

When no particular storm about the time of the spring equinox (March 21), if a storm arise from the east on or before that day, or from any other part of the compass near a week after the equinox, then in either case the succeeding summer will be dry four times out of five; but if from the S.W. or W.S.W., on or just before the spring equinox, then the summer following will be wet five times out of six.—*Dr. Kirwan.*

Walton-on-Thames.

S. BILLING.

[The foregoing table will be found, in the same form, and almost word for word, in "Time's Telescope" for 1814, second edition, p. 357; also in "Time's Telescope," 1831, p. 411; also in "Time's Telescope," 1824, p. 200. These are the only volumes of the work we are enabled to refer to. It will be found, in a slightly modified form, but the same in purport, in vol. ix of the "European Magazine," p. 24, and is there ascribed to Dr. Herschel.—Ed. G. M.]

CUCUMBERS AND PINES IN A QUEER SORT OF HOUSE.—"Every heart knows its own bitterness;" but still there are men who hope against hope, until that hope, although it may be but dim, fades away into nothingness. Gardeners at all times, and even under the most favoured circumstances, have doubtless as many hindrances to success as any other class of men we could mention; but how frequently those hindrances are augmented to an undue extent in numerous and varied instances! The other day, in my rambles I passed through a house construct'd on the following plan: The exact length I do not know, but some'ing like 30 feet; the back wall is 16 feet from ground level, and the front wall 4 feet. At an angle of 75 degrees are placed 10-foot length lights, and at that point another angle is formed, where lights are continued to the back wall at about 40 degrees, thus forming what is called a "hipped roof." The width inside is 8 feet 6 inches. There is a pit 6 feet wide the whole length of front, with six 4 inch pipes for bottom, and two 4-inch and one 3-inch pipes for top heat. The whole is composed of iron and best plate-glass, with a south aspect, with ventilation not ample. Now this house was built for the growth of cucumbers, and the gardener told me he had grown some good stuff early and late, but in the summer months the plants were "scorched to death." Subsequently the house has undergone some slight internal alterations, and is now, as I have described it, appropriated for pines. Every one knows his own circumstances best; but if such a house was so constructed by my employer, after my protesting against its adaptability, I should be disposed to tell him in plain English either to attend to it himself, or call in the services of some one to release me of my responsibility. I have always found both cucumbers and pines to require more atmospheric moisture than, it appears to me, is possible to acquire or retain in such an oven-aired place. Perhaps you will kindly say, if any man with ordinary skill in the cultivation of the pine might or might not successfully grow them in such a place. The matter has been naturally talked over by several gardeners of this neighbourhood who are readers of the "Magazine," and a word from you, or any of the practical friends whose names we so often see in our weekly *impartial* Magazine, would I am sure be read with interest, and not less so by the craft in general. W. H. SMITH.

King's Heath, Birmingham.

RESTORATION OF GRASS-PLOTS.—Some weeks since I read in the GARDENER'S MAGAZINE the use of nitrate of soda to a lawn. I ordered 7 lbs., thinking it would be sufficient for a lawn of about 60 yards by 20. But on discovering that a square rod (on which 4 lbs. were to be put) was only 5½ yards square, I have only tried it on a limited scale. The grass has become thicker and a lovely colour, except where pieces fell about the size of a small sweet-pea; there it was burnt. My object in writing is to ask you to be so kind as to inform me where I can procure the nitrate of soda at a cheaper rate. This small quantity cost 4s. 1d.; it came in such large lumps it had to be pounded in a mortar, which, if a large quantity were used, would be troublesome. J. V.

[Cheap manures are scarcely to be had in any part of the country, and to obtain the commonest salts or alkalis is not always an easy matter. We see nitrate of soda entered at £12 10s. per ton in the last market letter. The rate at which we recommend it to be used—i. e., 4 lbs. per square rod—is equal to about 6½ cwt. per acre, just double the rate which agriculturists consider proper when this manure is applied on a large scale. At the rate of 6½ cwt. per acre, the cost per rod will be about 7d. J. V.'s lawn measures 60 by 30 yards, or about 1 rod; as there are 40 rods to a rod, the cost for the whole should be about 24s., supposing the nitrate to be purchased at wholesale price. Let us now allow the drysalter a liberal profit, and this lawn ought to be dressed for 30s. at the utmost. Good superphosphate of lime sells in market at about £6 per ton; and if a growth of clover is desired, is a better dressing for a lawn than nitrate of soda.]

Replies to Queries.

Cocoa-nut Fibre Waste.—E. Payne.—This material may be put to a great variety of uses besides the formation of beds for plunging pot-plants. As a plunging material it is the best of all, because of its equable temperature, constant moisture, extreme cleanliness, and the general dislike of vermin to harbour in it, though as it decays vermin take to it as if it was spread for their reception. It has been employed, unmixed with any other kind of soil, for the growth of ferns in closed cases, and answered admirably; the ferns grew with vigour, required but little attention, and after two years' residence, with no other soil but pure cocoa-nut fibre, were in perfect health, and greatly increased beyond their original dimensions. But when it was attempted to transfer these ferns to a peat soil, or rather when they were disturbed in any way, or if a little extra air was given it, it was observed that they had less power of endurance than ferns of the same kinds grown in the same way, but with a more substantial soil to root in. Another of its uses is for propagating. Any and every kind of plant will make roots in this material more quickly than in any other, and many plants will throw out roots after their branches have merely rested on a bed of it for a few days. But here again let us observe a fact that, as in the last case, detracts from its value. Cuttings rooted in the fibre should be potted off properly as soon as ever the roots begin to push, otherwise the roots are of the same sort apparently as those formed by cuttings immersed in water, and which usually perish when the cuttings are transferred to earth, leaving the cuttings to the second effort of producing earth-roots in place of the water-roots lost. With judicious management this fibre may be used in every kind of propagation, but we should be prepared to transfer the little plants into suitable soil as soon as they begin to form roots. Another use for this material is to ameliorate and improve any tenacious soil, and the better fit it for the growth of certain kinds of plants. We have hitherto spoken of its use *pur et simple*. When mixed with thrice its bulk of common garden loam, or even with crumbs of clay (by "crumbs" we mean the granulated surface of a bank of clay that has for some time been exposed to the weather, when the top crust breaks up into crumbs of the size of beans and peas), it forms a compost in which almost any robust habited ferns will thrive, and which will suit almost every kind of greenhouse plant. We have grown fuchsias in a mixture of equal parts loam and fibre, and they grew luxuriantly and flowered well, and we have grown scolopendriums in variety in a similar mixture, and in fibre and crumbs of clay, and they presented a beautiful glossy appearance, and were in every respect luxuriant and healthy. Another use of the fibre, where it can be obtained sufficiently cheap, is to dig in where the soil is heavy, or where, as on chalk, it is much parched in summer time. It effects an immediate improvement, and being retentive of moisture is a great assistance to vegetation during summer drought. It is generally supposed that this stuff is destitute of nourishment, but that is a mistake. What are its mineral constituents we do not know, but undoubtedly it contains alkalies and other essentials of vegetable growth, and during its decay a considerable amount of carbonic acid must be liberated, which is a direct aid to plants, and perhaps explains the peculiar suitability of this material for the growth of ferns.

Vines Injured.—G. Bromley.—It is quite certain that your vines have been nibbled by animals of some sort. Crickets may have been the marauders, and as you have found a few of these vermin, the cause of the injury may be thereby explained. But we think it much more likely that the depredators are rats or mice. We know too well that rats and mice (separately, never together) will thrive in viciaries during the summer, and will even condescend to eat geraniums. Only within the past few weeks we have ourselves lost some variegated seedlings, which were eaten close off, and the soil from the pots was dragged about in a way that no insect could accomplish. Your best course is to employ poison, and there is nothing better than carbonate of baryta, mixed with lard or damp flour, or thinly powdered on bread-and-butter. It is a deadly poison, and must be used with caution. The best way to poison rats and mice is to prepare the stuff nicely, using good bread and good butter, not to touch it at all with the hands, and then carefully to hide it under some dry bricks or broken flower-pots. If handled and laid in an exposed position, these cunning gents will be suspicious of it, and your labour may be all lost; but if not touched with the hand, and then put away as if hidden from them, they will consume every scrap, and give up the ghost.

Variegated Geraniums.—Greenhorn.—Probably yours only require to be placed in the sunshine out of doors to acquire their proper colours. Read over Mr. Smith's paper on the subject, published five or six weeks back.

Green-fly in Greenhouse.—Subscriber.—Procure one of Gidney's self-acting fumigators (from Mr. Gidney, East Dereham, Norfolk), and fumigate the house thoroughly with the best shag tobacco. The best time to fumigate is the evening; the plants should be dry, and the house closely shut. Early next morning syringe them well, and a couple of hours after the syringing give air. Gidney's fumigator is furnished with a spirit-lamp, so that having filled the receiver with tobacco, it only remains to light the lamp and walk away. The instrument then delivers a cool dense cloud until the tobacco is all consumed. If the purchase of a fumigator is objected to, take a large flower-pot, throw into it a few red cinders from the fire, and then fill up with Collyer and Roberts's tobacco-tissue, broken into pieces about the size of the hand. This "tissue" consists of the best tobacco in a pure state, and it burns away to the last particle without breaking into a flame.

Cucumbers, &c.—James Luck.—Your cucumbers appear to be wholly dependent upon sun-heat, and as this season we have sun-heat in excess about one day in ten, and the other nine a winter temperature, they live in a series of jerks, growing freely for a short time and then having a serious check. The real want in your case is bottom-heat; secure this by fermenting material or otherwise, and your troubles will cease. It is possible that you give too much air. Your hulk is one of the amaryllis tribe, but we cannot name it from a sample of the skin. The only manufactory of flower-pots we can recommend for you is Messrs. Adams Brothers, Belle Isle, King's Cross, London, just convenient for you to obtain them by rail. If you want the largest sized pots for valuable plants, there are none so good as those made by Messrs. Phillips, Weston-super-Mare.

Stocks and Asters.—Flora has but to read the several papers that have appeared in the Magazine, as for example that at page 98 of the present volume (March 9, 1867), to learn all that books can teach on the subject. Any light rich soil will do for these things, and damping-off is best prevented by giving water cautiously while the plants are very small. Frequently delicate plants in seed-pans are destroyed by vermin that eat through the stem close to the soil, and so sever the head from the root. Many cases of failure described as "damping-off" are really the result of

cating off by such grubs as that of *Tipula oleracea*, of which sometimes the soil in seed-pans contains many. If Flora will refer back to March 9, 1867, and March 11, 1866, she will find abundant information on these matters. It is a good plan, to prevent destruction of seedling plants by vermin, to water the soil in the seed-pans with boiling water, and set them aside for a few days before sowing the seeds.

Lilium hamatochromum.—D. K.—This liliun was figured in the *Illustration Horticole* for January, 1867. It is stated in the description that it was obtained from Japan by M. A. Verschaffel, Rue du Chaume, Ghent, but it is not stated whether it has yet been offered for sale.

Herbaceous Calceolarias.—We have received from "J. E." Chorley, Manchester, a boxful of flowers of herbaceous calceolarias, as samples of "Neill's extra choice strain." The flowers were packed in a most skilful manner, and came to hand as fresh as if but just gathered. In quality they were equal to any we have ever seen, and far better than the average. Large without coarseness, beautiful in form, and of refined texture, and delightfully various in colours and markings. We should prefer this strain to some that are in high favour, because of the fine character of the flowers. The originator of this strain is Mr. Neill, gardener to Mr. Martin, of Rivington.

Mildewed Peach Trees.—E. L. G.—Paint the affected parts with a solution of Gishurst compound, 2 oz. to the gallon.

Calceolarias.—Stafford.—It is impossible for us to say why calceolarias will not succeed in your garden. There are thousands of gardens—ay, tens of thousands of gardens—in which they do not thrive. Probably, as this is a cold wet season, and all tender bedding plants are perishing, the calceolarias may do well, for it is in hot dry seasons usually that they die off. We have treated of the whole case many times, and really cannot go into the subject again. The last we had to say on the subject was to this effect, that calceolarias planted in a mixture of equal parts rotten hothed dung and good loam grew freely and flowered profusely, while others planted in common garden soil were perishing. And again, calceolarias planted in a bed made up of rotten manure only, without loam, made a splendid appearance when others in the same garden were only fit for the muck-heap.

Cherry Tree.—W. S.—It is quite likely that the soil is not well adapted for the tree, a conclusion confirmed by the bad behaviour of the Morellos close by. After seven years of failure it is useless to expect to mend matters by any patchwork; a radical cure is wanted. Prepare a station in September next, and in October move the tree.

Tacsonia Van Volxemi.—H. H. H. N.—Any of the nurserymen who advertise in the Magazine can supply this plant. Write to one and inquire the price.

THE RESTORATION OF A LONDON LAWN.

A very interesting exemplification of the ease with which apparently insurmountable difficulties may be overcome by skill, determination, and patience, is deserving of mention. An amateur who pursues horticulture in earnest, and who is compelled to reside close under the shadow of the Great Metropolis, has been perpetually fighting for his grass-plot, and to a great extent fighting in vain, for till now it has never been perfect during the ten years he has laboured at it. Its appearance, however, at the present time is that of a smooth, bright green Turkey carpet dotted with luxurious cushions of moss-like vegetation, out of which spring various beautiful coniferous trees, such as *Arancaria imbricata*, *Thujaopsis dolabrata*, &c. Perhaps a few particulars of the *modus* followed may be of interest. It must be premised, then, that the lawn has been twice laid down with the very best "forest turf," which is the name applied to a beautifully fine turf obtained from Wanstead. It has also been twice laid down with the very best grass-seeds. In spite of every care it becomes patchy, as it is much overhung with large trees—beautiful trees, too, that the owner would not cut back, though he wishes they would allow the grass to grow beneath them.

Well, the remedies have consisted in first marking out circles round all the trees that are planted on the lawn, and filling these circles with *Spergula filifera* or *Spergula saginoides* where the positions were fully exposed to light and air, and with *Sagina procumbens* where the positions were much shaded. These circles have all become filled with a dense moss-like growth; all the care they demand is occasional weeding, and those that rise into mounds are now and then beaten gently with a turf beater. But the worst parts of the lawn were those near the edges, where large trees made constant drip and shade; but these are now all velvety and deliciously green with the *Sagina procumbens*. This persistent weed was obtained from a neglected garden close by, where it had on its own account made a thick turf of an old gravel walk. All the patches requiring to be mended on the lawn were prepared by removing the soil a foot deep, and then filling up with the sandy stuff which had accumulated in the potting shed from the worn-out contents of flower-pots thrown out in the process of shifting the plants. The proprietor of the garden had observed that *Sagina* grows most freely in such stuff, especially if full of bits of brick and tile, as of course emptyings of pots are sure to be. The result is a perfect success. It is now the best London lawn I have ever seen.

H. S. J., in "The Field."

POLVERS' EGGS.—Of all wild birds' eggs the plover's are considered the best. They are chiefly laid on plough, pasture, and moor land, always in the ground, and are found by the country people, sometimes assisted by dogs trained for the purpose. The full complement is generally four; they are olive-coloured, spotted and blotched with black, and those who rob the nests are, it is said, careful not to take all, to induce the bird to go on laying, and this she generally does to make up her number. Next in estimation is the black-headed gull (*ridibundus*), being a genuine gull, and belonging to the swimmers, or more properly the *Laride*. The nests, contrary to the nomenclature of other gulls, which generally form theirs in the ledges of rocks near the sea, is placed in low situations. Nowhere are they more abundant than at Scoulton Mere, in Norfolk, and Twiggmore, in Seawley, Lincolnshire. At the former place, we are informed, 1,000 eggs per diem are gathered for two or three weeks every year, and the proprietor derives a good rental in consequence. They are often substituted for the plovers', and find their way to the Norwich and London markets, where they are considered dainties. The eggs, which vary much, are generally of a deepish olive, sprinkled with large brown and blackish spots. The birds are very regular in their migratory movements, for such their departure from and to the sea-coast may properly be termed, and their return in spring may in some cases be calculated upon almost to a day. We are given to understand, by a gentleman who has kindly furnished us with information, that rooks' eggs are very delicious, and, but for the difficulty of gathering, would be much eaten.—*The Grocer*.

The Gardener's Magazine.

SATURDAY, JUNE 15, 1867.

SUMMER HAS SUCCEEDED WINTER, and the year 1867 will be remembered as that in which we had no spring, for it would be absurd to designate by the familiar term "spring" the alternations from tropical heat to arctic cold by which the month of May was characterized, or the stormy, rainy, and frosty weather of the months of March and April. Now that vegetation is looking healthy, and the earth is warm, the sunlight is pure and strong, we may, without depression, reflect upon the trials we have gone through, and the truly treacherous nature of the climate of Britain. One meteorological fact has been deeply impressed upon the popular mind; the great race of the year, the Derby, was run during a snow-storm. A correspondent wrote from Nottingham, on the 23rd of May, to say that they had not only had plenty of snow there, but that it was lying on the ground, a most unusual circumstance at so late a period of the year. We have visited gardens and farms in the extreme west, east, and north during the past three months, and seen everywhere identical traces of the ravages of the past severe winter, and in eastern districts the successions of frost continuing quite till the dawn of June, wrought terrible mischief. Everywhere losses of a serious nature have occurred, and the potato crop has been put back a fortnight by the almost total destruction of the growing haulm on the 23rd and 24th of May last; for on the morning of the 24th there were but few plantations of potatoes but were as black as ink, and as uninviting as heaps of rags. The potato is recovering fast, but even now, when the growth is once more green and vigorous, there are still to be found shrivelled leaves and other traces of the terrible ordeal through which the plant has passed. There may be some interest in a few particulars of the peculiarities of the season as observed in our own trial ground at Stoke Newington, and we will briefly summarize them.

It is the rule amongst experienced cultivators of the cold clay soils on the north side of London never to sow seeds of any kind till about the middle of March. This rule we have ourselves followed pretty closely, but the temptation of an outburst of fine weather in February is not always to be resisted, and occasionally we have reaped substantial advantages by following the precept, "nothing venture, nothing have," and by extra early sowing have reaped extra early produce. On the venture theory, we sowed on the 20th of February last one hundred varieties of peas, twenty varieties of spinach, and a few other collections of esculents, and planted one hundred and sixty varieties of potatoes. The weather was then bright and promising, but very soon afterwards winter returned, and the peas had to struggle with cutting winds, frost, snow, and vermin, and though they came up as regularly as could be desired, they soon began to succumb to the unkind influences of the weather, and on the 2nd of May there was but one row in the entire hundred presenting a healthy and promising appearance, and that was the good old Ringwood marrow. The whole plantation was then destroyed and sown again, and the earliest sorts are at the present date blooming luxuriously, and will but be a little later in the first gathering than early peas in the same district that were sown in the middle of March, and that survived the frosts of May. The collection of varieties of spinach failed in a similar manner, the rows being patchy at the best, and several sorts failing to vegetate. On the 5th of May, about twenty-five varieties of kidney beans were sown, one of them a quite new and valuable kind of our own, which produces scarlet pods, and of which it was desired to obtain a stock of seed. These were just pushing through, when the bitter frost of the 23rd smote them, and very nearly completed their annihilation; the rows are now dotted with green at two or three yards apart, where a plant here and there has pushed through since the frost, and they might as well be destroyed as kept for any use they will be, to say nothing of the miserable appearance of rows of beans consisting of single plants a yard or two apart. This loss, including as it did a novelty we are anxious to multiply, reminds us that the Newington Wonder pea, figured in our report on peas last year, and the best pea probably ever raised, is almost No. 111, NEW SERIES.—VOL. X.

lost, for only two miserable plants remain of it, and one hungry snail could finish them both in a night. We had three quarts of the seed, and sowed it all with the rest of the collection on the 20th February. This is a forcible lesson in illustration of the "nothing venture" theory; it may be well to venture with things that can be easily replaced, but it was evidently a mistake to risk the small stock of a new variety in opposition to the traditional wisdom of the locality. Happy shall we be to obtain two or three pods of this variety wherewith to begin again. Cauliflowers have behaved strangely. Our winter kept stock of Early London and Walcheren made a rush in growing during the warm weather in the middle of February, and the plants became so gross that we were afraid they would button in the frames. They were therefore planted out in the middle of March, and about a sixth part of the whole perished very soon afterwards. But those that stood their ground have done well, and we began to cut on the 25th of May, the heads being then small but good, and the Early London has since that date kept up a continuous supply, and the Walcherens are now nearly ready for a first supply of good heads. The winter is past no doubt, and the rapid growth of vegetation consequent on a flood of sunlight will soon obliterate the traces of the trying season through which we have passed. Let us hope that after all Plenty will crown the year, and that our losses will be forgotten in the abundance of our gains. There is plenty of grass, and cereals have improved wonderfully, and we may begin to talk of "the season and the crops" in a hopeful spirit and in faithful reliance upon Providence to give us our meat in due season.

CITY GARDENING IS LOOKING UP. We can add to the list of pretty gardens in the city of London two new examples of "how to do it." In a little churchyard on Fish Street Hill, where dinginess of the extremest dingy sort has been the rule time out of mind, may now be seen a pretty rockery tastefully made and appropriately planted. It is perhaps not the best place in the world for a rockery, but we must not be hypercritical. Better that than dirt; better anything green and cheerful and alive than sour soil looking as if plague-struck, and a standing disgrace to churchwardenism. In Watling Street, on the site where used to stand the church of St. John the Evangelist, is an example of what we will venture to pronounce a perfect model of city graveyard gardening, though the spot is not and never was a graveyard. There are a few tall and beautiful plane-trees, and beneath them a circular bed, a circular gravel walk and borders for the boundary, all the lines marked out with a neat edging made of Rosher's patent stone. The bed and the borders are planted with shrubs, and in all suitable places on the walls and railings there is a screen of Irish ivy. The shrubs employed are Holly, Box, and Rhododendrons, and the effect is not only pleasing but is really tasteful; in fact, this is as pretty a garden of its size as will be found anywhere in the city of London. The immediate promoter of this improvement is Mr. James Crute, of the firm of Crute and Downing, a gentleman whose taste and spirit in the patronage of horticulture is well known to our readers. We invite our London readers to make a visit to Watling Street for an inspection of Mr. Crute's work, and we respectfully admonish all who have the guardianship of similar enclosures to do likewise.

AN INTERNATIONAL ROSE SHOW is proposed by Mr. George Paul, to be held at Boulogne next year. The proposal is worth careful consideration. The French rosarians would no doubt enter into the project heartily, but it would need the hearty co-operation of English growers to render it successful, and, in fact, to give it an international character. It is, of course, too late to say much about it for the year 1867. If it were attempted to carry it out this year, it would fail, but the idea may be cherished with a view to its realization next year.

BAD SEEDS have been sold more largely than usual during the present season. In many instances such chaffy seeds as those of carrots, parsnips, stocks, asters, and lettuces have germinated very unequally. The blame must not all be cast on the seedsman, for he must provide seeds according to the best of his ability, and in 1866 very many kinds of seeds were an entire failure, and to meet the requirements of the market old stocks were resorted to. Chaffy seeds kept in large bulk are more or less good the second year; but kept in small bulk are generally worthless. But large fleshy seeds may be kept, generally speaking, for many years without suffering deterioration. It would be well, however, if seedsman were to announce the fact of their being compelled to send out old seeds; they would be the gainers in the end by plainness of speech. Messrs. Wheeler, of Gloucester, announced that they had failed to ripen seed of their Tom Thumb lettuce, and were dependent on imported seed. We have grown a good stock from their sample, and there is no inferiority in the produce as compared with the best samples of former years.

NATIONAL HORTICULTURAL EXHIBITION,

MANCHESTER BOTANIC GARDENS, JUNE 7TH TO 15TH.

The Manchester exhibition has proved a brilliant success, and in every sense an honour to its promoters. The most experienced habitués of horticultural gatherings pronounced it the second-best meeting of the kind they had ever attended, and by a large majority of the exhibitors, judges, and professional visitors, it was regarded as, in every sense, the most interesting and comprehensive, and at the same time the most effective display of horticultural productions amongst the many such that have taken place during the past few years. Some account of the arrangements appeared in these columns prior to the opening of the show, and we are now bound to say that there was nothing extravagant in the tone of the anticipations that accompanied our brief descriptions of the preparations that were in progress, for the splendour of the display far exceeded the expectations of the most sanguine of the promoters. The garden at Old Trafford is admirably adapted for a fête of this sort. It is situated in a rural district about two miles distant from the city of Manchester, and has ample breadths of lawns and walks for promenading, and the great show-house is an elegant structure, eminently suitable to the purpose both for the convenience of visitors and for the display of plants and flowers with the best possible effect. On the present occasion the exhibition house was occupied with only a part of the vast collection of subjects contributed, for beyond it was a great tent, the ground-work of which was laid out in grass banks and mounds and spacious walks between, and here a gorgeous effect was produced by the judicious grouping of azaleas, roses, pelargoniums, and palms, and tree-ferns, the great sheets of colour being judiciously relieved with rich masses of greenery. We thought there was a want of perspective in the design, but as tastes differ we may be quite wrong in our judgment on this point, and it is a pleasure to set aside that objection, and call to mind the beautiful appearance of the scene, and the high merit of the greater part of all the subjects exhibited. The exhibition house, which became for the time a vestibule to the great tent, was occupied with orchids and groups of stove and greenhouse plants, and in the centre was a table covered with fruits. On entering the tent from thence, the visitor felt as if suddenly transported to some happy island,

Where spices breathe and fragrant roses smile;

for he found himself suddenly immersed amongst masses of gay flowering plants set out on grassy banks in the picturesque style which has long and successfully prevailed at Regent's Park. Having traversed this tent, there yet remained another placed parallel to the exhibition house, and forming the lower part of the letter L to the larger tent. In this were collections of novelties of all kinds, also of calceolarias, zonale pelargoniums, ferns, alpines, and miscellanies. These arrangements were admirable. The learned were gratified by the display in the exhibition house, pleasure-seekers had their fill of floral beauty in the great tent, and the foot of the letter L made a capital rendezvous for conversation and for orities to make and compare notes on novelties. The schedule comprised 80 classes in all, but few of which were not well occupied with entries, and as to the character of the contributions, our report will show that it was of the highest class possible in a competition maintained by the leading horticulturists of England and Scotland. Mr. Findlay, the orator of the Manchester Botanic Garden, has been the guiding spirit in all arrangements from the first, and to his skill, perseverance, and kindly courtesy is the city of Manchester indebted in a large measure for the honour of having attracted horticulturists and botanists from all parts of Britain to assist at and to enjoy one of the most splendid exhibitions of modern times.

ORCHIDS were the most important, as to their value and condition, of all the subjects shown, and it was a matter of equal satisfaction to professional visitors as to the cultivators of the district, that Manchester had the foremost place in this competition. The first prize in the class for twenty was taken by Mr. Toll, gardener to J. A. Turner, Esq., with a group comprising well-grown examples of several kinds that are rarely seen in a specimen condition. The following are the names of the plants shown in this group:—*Aerides affine majus*, 4 spikes out and one coming; *Saccolabium ampullaceum*, a fine healthy plant, in a state of free growth, bearing 13 spikes of perfect flowers, far surpassing average examples of this scarce orchid; *Oncidium bifolium majus*, 5 spikes of flowers, extra large in size, and of the purest yellow colour; *Cattleya mossiae*, good; *Saccolabium guttatum giganteum*, 3 spikes, glorious for size and colour; *Dendrobium Parisbii*, with 16 flowers; *Saccolabium guttatum splendens*, *Cattleya elegans Warnerii*, *Oncidium phymatochilon*, one great spike of its very insect-like flowers; *Vanda suavis*, *Aerides Lindleyana*, *Cypripedium barbatum*, *Odontoglossum navium majus*, *Saccolabium præmorsum*, *Cœlogyne pandurata*, an unattractive but not unhandsome orchid, the flowers green with black spots; *Cypripedium barbatum superbum*, *Aerides Dayanum*, *Vanda tricolor*. The second place was awarded to Mr. Brocklehurst, gardener to A. Turner, Esq., who, though unquestionably second, had some very good pieces. Here we found a superb *Oncidium cordatum*, with 2 spikes, one full out, the cinnamon colouring true; *Odontoglossum Uro-Skinnerii*; a fine *Odontoglossum Pescatorei*, *Phalænopsis Schilleriana*, with one spike; *Cattleya mossiae*, *Oncidium sphaacelatum*, *Saccolabium guttatum*, with 6 spikes; *Cattleya Aclandii*, *Phalænopsis grandiflora*, *Odontoglossum navium*, good; *Calanthe veratrifolia*, had, the leaves yellow, and the plant small; *Oncidium ampliatum majus*, *Cypripedium barbatum*, *Oncidium phymatochilon*, *Cattleya lobata*, *Anguloa Ruckerii*, *Burlingtonia fragrans*, *Epidendrum cochleatum majus*, a fine plant, the merits of which were variously estimated, but which is certainly worth a place in every collection, for it has beauty if it is not attractive, and it is well adapted to bring out the best characters of other orchids. The third place in this class was assigned to Thomas Jones, Esq., who had examples of *Sobralia macrantha splendens*, second-rato in colour and substance; a good *Saccolabium Holfordii*, *Oncidium Phalænopsis*, with 6 flowers, fine; a good *Trichopilia crispata*, *Anguloa Clowesii*, *Aerides Fieldingii*, and others of less importance. In the nurserymen's class for twelve, the first place was taken by Mr. B. S. Williams, of Holloway, London. In this group was a beautiful example of the rare *Cypripedium Hookerii*, a large and finely flowered *Dendrobium cœrulescens*, *Oncidium sphaacelatum*, *Cypripedium villosum*, with nine of its huge flowers; *Dendrobium densiflorum*, with about 30 spikes; and an extra fine *Cypripedium barbatum superbum*. Second, in the trade class for twelve, Mr. John Shaw, of Bowdon. In this group a good *Lælia purpurata*, *Cypripedium Stonei*, *Oncidium sphaacelatum*,

and *Brassia verrucosa*. Mr. Stafford, nurseryman, of Hyde, near Manchester, exhibited in this class some small but pretty pieces, amongst them a nice *Cattleya citrina*. In the amateurs' class for twelve, Dr. Ainsworth (gardener, E. Mitchell) took the lead with a truly noble group. Here we found one of the best plants of *Oncidium ampliatum majus* in the show; a fine *Vanda suavis*, *Vanda tricolor*, *Aerides Lindleyana*, *Aerides Fieldingii*, *Aerides cornutum*, *Saccolabium guttatum giganteum*, *Phalænopsis grandiflora*, *Oncidium hastatum*, *Cattleya mossiae*. The second place in this class was allotted to Mr. Toll, gardener to J. A. Turner, Esq., for *Cattleya mossiae*, *Saccolabium guttatum giganteum*, *Cattleya mossiae Turneri*, fine large flowers of a soft silky texture, colour warm blush, lip fringed, rich magenta veins, buff yellow throat; *Odontoglossum cordatum*, *Barkeria melanocaulon*, and a beautiful *Dendrobium chrysotoxon*. Third, Mr. Baker, of Old Trafford. In this lot the curious and unattractive *Oncidium hastatum*, *Cetasetum cernuum*, *Dendrobium densifolium album*, fine; *Aerides Fieldingii*, *Saccolabium Blumei* Dayii, *Calanthe veratrifolia*, *Vanda suavis Veitchii*, *Cattleya mossiae*, *Saccolabium retusum*, *Vanda Roxburghii*, and Backhouse's variety of *Lælia purpurata*. The first place in the class for eight was assigned to Mr. John Stevenson, of Lark Hill, who had a splendid *Dendrobium densiflora alba*, with 11 grand spikes; *Cypripedium barbatum superbum*, *Odontoglossum navium*, *Saccolabium præmorsum*, *Cypripedium lævigatum*, *Dendrobium nobile roseum*, a very poor *Phalænopsis Luddemanni*, and *Aerides Fieldingii*. Second, Mr. T. Kendall; third, Dr. Ainsworth. In the class for single specimens, there were a few superb pieces brought forward. The first prize was awarded to T. Kendall, Esq. (gardener, George Houghton), for a noble plant of *Saccolabium retusum*, with 4 perfect spikes, most richly coloured. Second, Thomas Jones, Esq., of Whalley Range, with *Phalænopsis Luddemanni*, with 8 flowers, the finest specimen no doubt hitherto exhibited. That it did not take a first position appeared to surprise some who consider value of more importance than beauty; but if beauty was mainly sought for by the judges, Mr. Kendall's *Saccolabium* certainly bore away the palm. Third, Dr. Ainsworth, with the rare and beautiful *Trichopilia crispata marginata*, with 21 flowers. This variety is of a darker and richer colour than the type of the species, and has a clear white margin. It is a curious circumstance that there were but two examples of the lovely *Lælia purpurata* in the whole of this splendid display of orchids, and of *Cattleyas* there were not many.

STOVE AND GREENHOUSE PLANTS.—Mr. Baines, gardener to H. Micholl, Esq., Manchester, took first place in the class for fourteen, with extra large specimens of the best exhibition plants in a wonderful state of freshness and finish. *Dipladenia crassinodes*, quite covered with its charming rosy flowers; *Ixora coccinea* and *I. aurantiaca*, both very fine; *Aphelexis humilis rosea*, a very fine *Franciscea confertifolia*, *Erica tricolor* Leeana, *Azalea Stanleyana*, *Acrophylla venosa*, a good *Hedera*, and a rather thin *Dracophyllum*. The second place in this class was awarded to Sir James Watts's gardener, and the third to Mr. Mitchell. In these collections *Ixoras* were conspicuous for splendour, and there were good examples also of *Stephanotis floribunda*, *Tetratheca ericoides*, *Erica ventricosa Bothwelliana*, *Rhyncospermum jasminoides*, *Acrophyllum venosum*, and *Aphelexis*. In the amateur class for eight, Mr. John Stevenson, of Lark Hill, took first place with a superb group, comprising the finest *Ixora amboyensis* in the show; a *Pimelia mirabilis* about six feet over, a solid convex sheet of rosy flowers; *Erica eximia superba*, *Clerodendron Balfourii*, *Acrophyllum venosa*, *Azalea Gem*, *Erica Cavendishii*, and an *Aphelexis*. Second, T. Kendall, Esq., with a very fine *Pimelia Hendersonii*, *Erica Cavendishii*, *Azalea Criterion*, a good *Franciscea*, and others. In the class for four the awards were to Mr. Kendall, Sir J. Watts, and Mr. E. Phillips, in the order named. The trade class for twelve was led off splendidly by Messrs. Cole and Sons, of Withington, who presented huge plants of *Erica Paxtoniana*, *Aphelexis macrantha purpurea*, *Ixora coccinea*, *Ixora amboyensis*, *Erica Cavendishii*, *Azalea Criterion*, *Azalea Sir Charles Napier*, *Pimelia mirabilis*, *Acrophyllum venosum*, *Dracophyllum gracile*, *Azalea Iveryana*, *Genetyllis Hookeriana*. Mr. B. S. Williams, of London, contributed a group, comprising handsome pyramid *Azaleas* and other plants of the same kinds as have been already enumerated. Messrs. Cole were again first in the class for six, with *Aphelexis purpurea*, *Erica Cavendishii*, *Azalea Duc de Nassau*, and others.

FINE FOLIAGED PLANTS were abundantly produced, and the noblest group of all was that comprising ten plants from Mr. Mitchell, gardener to the Duke of Hamilton. Here we found by far the finest examples of *Phœnicophorium sechellianum* we have yet seen; a grand *Dasyliroium glaucum*, *Pandanus ornatus*, *Theophrasta imperialis*, *Croton angustifolium*, a gigantic and bright green *Latania Bourbonica*, *Cordyline indivisa*, *Pandanus elegantissima*, *Croton variegata*, and a *Dracæna*. Mr. Stevenson came second with a beautiful group; Mr. T. Hobson third. In the amateur class for six, first, Mr. Schloss; second, Mr. E. Phillips. In the trade class for twelve, Mr. B. S. Williams took first place with glorious examples of *Yucca aloifolia*, *Theophrasta imperialis*, *Croton pictum*, in a brilliant state of colouring; *Pandanus reflexus*, and other noble plants. Mr. Shaw second, Mr. Stafford third. In the class for three palms, Mr. Mitchell, gardener to the Duke of Hamilton first, Mr. Broome second. Mr. Baines first in three ferns. The finest group of Stove and Greenhouse Ferns came from Mr. B. S. Williams, second, Mr. Shaw. Mr. Williams also contributed the best group of *Dracænas* and *Cordylines*, second, Mr. Stafford. Again, in the class for *Yuccas* and *Beaucarneas*, Mr. Williams stood first, and Mr. Shaw second. In these several collections the superior size, beauty, and value of the specimens from Holloway gave them a quite distinctive character, and won for Mr. Williams golden opinions. There were beautiful collections of ferns from Mr. Hobson, Mr. Stevenson, Mr. Broome, Mr. Hampson, Mr. Pearson, and Mr. Rowthornam. In the trade class, Messrs. Ascroft, of West Derby, and Stafford, of Hyde, exhibited collections of thirty-six hardy kinds.

AZALEAS.—We shall deal with these in a summary manner. As we have already given full lists of the best varieties exhibited at the metropolitan exhibitions, there will be no need now to analyze the collections, especially as they consisted of well-established kinds that are known to be the best in the several classes. But we have something special to say about them, though we shall not make lists of names. There were collections from Messrs. Cole and Son, of Withington; Messrs. Lane and Son, of Berkhamstead, Herts; and Mr. B. S. Williams, of Holloway, London, all grown in the London style—that is to say, in the form of regular pyramids, equally furnished all round with leaves and flowers, and in beautiful finish of training. There were also several collections from amateurs, notably from Sir J. Watts's gardener; also from Mr. Hauner and Mr. Baines. Our notes do not tell us whether the last named is to be condemned with

the rest of the amateurs for contributing Azaleas which were of great size, full of bloom, but hideous through a false system of training. We are so accustomed to see Mr. Balnes's plants trained symmetrically, that at the moment of writing this report we think it probable that his Azaleas were fit to be seen, but it is quite certain that a considerable proportion of those contributed by amateurs were trained to a face, that the face was the quintessence of ugliness, and the profile unlike everything else in heaven or earth, except sin perhaps, and the back view disclosed a mass of rude and obtrusive scaffolding. Impartial reporting is the rule we follow, and we must risk offending the gentlemen who contributed the great Azaleas that made so brilliant a display of colour on the grass mounds, by saying that we would rather see such plants committed to the flames than admit one of them to a decently-furnished plant-house.

ROSES.—The show was decidedly weak in roses; but as Messrs. Lane and Son, of Berkhamstead, Herts, took the first prize in the class for ten with grand pyramids; and Messrs. Paul and Son, of Chesham, Herts, took first prize in the class for sixteen with beautiful round bushes; and, again, Messrs. Paul and Son first for six, and Messrs. Lane and Son second,—there were many beautiful examples presented, and they were thoroughly appreciated. The climate of Lancashire is not the best in England for the rose, and the suburbs of Manchester are still less adapted for it. Nevertheless we should have been gratified if the lovers of roses in the district had made an effort to show the best that could be done thereabouts. Céline Forestier was shown with flowers of a rich lemon yellow, by Messrs. Paul and Son; Mr. Ashcroft, of West Derby, and Mr. Shaw, of Manchester, also exhibited.

PELARGONIUMS.—Mr. May, of Bedale, Yorkshire, presented a splendid bank of ten show plants of the large-flowered section, and a bank of ten beautiful fancies. These were even in size and bloom throughout, and perfectly fresh. Mr. Rylance put up the second-best group of ten fancies, treading very close on Mr. May's heels in this class, but finally losing first place, as at least three of his plants were not full out, and they were not so uniform in size and shape as Mr. May's. Mr. Rylance also exhibited six good fancy varieties. Show pelargoniums from amateurs were thoroughly good; and it is not often we see finer plants than the first prize six from Mr. Agnew. The second place was awarded to Mr. J. Broome for nicely-finished plants. Mr. Agnew was also first in the class for six fancy varieties, with splendid plants, fresh and sparkling; Mr. Broome second. Zonate pelargoniums were not well shown in any case. We should have rejoiced to see a few groups of large convex plants, such as are now commonly to be seen at the great London exhibitions, for this especial reason, that they are plants well adapted for great smoky cities like Manchester, where roses and some other favourites scarcely do well. The cultivators of Lancashire, in common with cultivators in many other places, have apparently not yet made acquaintance with the broad-petalled varieties of the florists' type, and have not yet turned their attention to the production of fine specimens of any of this race. The best ten zoned varieties came from Mr. H. K. Balstone, and the best ten variegated from Captain Starkey. Messrs. Phillips and Lees also contributed. In the trade classes, Messrs. Yates, R. Barnes, of Macclesfield, and J. Shaw, were the principal contributors. But here we must make an agreeable exception in favour of the exhibitors who put all other contributions in the variegated-leaved classes into the shade by their splendid groups of plants. Mr. Wills, gardener to Captain Starkey, of Huntroyde, noted above as first in the class for ten, presented a splendid group, all seedlings of his own, we believe, and mostly of the race of which Luna is the accepted type. We must go through this lot in detail, for they are destined to become famous in a very short time hence; in fact, only need to be seen by cultivators of these plants to be entered at once in their lists of the best varieties known.

Her Majesty, the most remarkable of all the brown zoned kinds; leaf medium size, round, and nearly flat, very small yellowish-green disk, and very broad bold zone of reddish cinnamon colour; the habit compact; a glorious and novel display of colour. *Beauty of Calder-Dale*, in the same style, but one shade darker in colour, the zone being nearly a pure chesnut. *Princess Beatrice*, a fine strong habit, disk and margin of yellowish green, bold brown zone, very rich and striking. *Model*, large green disk, scalloped chesnut zone, not so good as others in the group. *Beauty of Ribblesdale*, apparently not a good habit; perhaps, being quite a new variety, the plant may have been cut at over-much, and had not yet made itself for show; at all events it was a little leggy; leaf, sulphur-green or lemon-yellow; narrow red cinnamon zone, in the younger leaves shading towards pure red; very distinct and beautiful. *Huntsman*, large and coarse, but handsome; disk and margin of young leaves pleasing pale green, with bold notched zone of deep iron-rust red; the older leaves look rather washy. *Florence*, a grand tricolor in the Pollock style, with splendid shades of red and black in the zone; indeed, the black colour is one of its most distinctive and beautiful characters. For a pot specimen in a group this cannot be surpassed, but it does not look like a bedder. *Magnet*, very compact and neat-habited, and appears to be quite in advance of Luna. *Bridesmaid* a beautiful creamy-leaved variety, the leaves slightly convex, but quite round and neat; small rayed disk, with traces of a dusty zone; the rest of the leaf clear creamy white; a very fine variety. As to the flowers of these there were a few trusses of scarlet amongst them, and they would have looked better if these had been picked off. We have disagreed with Mr. Wills on theoretical matters, but we have nothing but unqualified praise to utter in reference to the best of his varieties, and his mode of presenting them. They were as bright as if horn and bred in a world where dust is unknown. Another pleasing feature was a group of tricolor-leaved varieties, from Messrs. E. and A. Smith, of Dulwich, London, and for which an extra prize was awarded. Here was the celebrated *Jetty Lucy*, one of Messrs. Smith's best; the leaf round and flat, with a brilliant red zone; *Defiance*, with very much yellow in the leaf, and the zone a good red; *Impératrice Eugénie*, the edge creamy, the zone bright pink; *Eclipse*, quite a novelty, the disk rayed, the leaf almost wholly yellow, sharp zone of bright carmine red; *L'Empereur*, exceedingly neat, the greater part of the leaf pale yellow, the zone brilliant red. There were others of scarcely less merit of which we had no time to make notes. Mr. Watson, of St. Alban's, brought three tricolors: *Miss Watson*, has a round flat leaf, with yellow margin, and a fine zone varying from red to pink, a splendid variety; *Mrs. Dix*, a compact, round-leaved variety, with splendid zone, first-rate every way; *Mrs. Gladstone*, leaf large, and much lobed; the colours are good, but there is a roughness inclining to coarseness in the plant, and it does not win upon us as we become better acquainted with it. Mr. Watson also brought forward a good nosegay variety called *Excelestior*, the flowers of which are a fine cerise red. Mr. Cunningham exhibited his pretty creamy-edged, ivy-leaved variety called *L'Élegante*, which will be a

most valuable plant for edgings, and when grown in the full sunshine will probably show a good tint of pink in the leaf, as there are traces of colour in its obscure dark zone. Mr. Wills put up a collection of new variegated-leaved varieties, but they were such small plants it was impossible to judge them fairly. The best were *Fanny*, a pretty medium-sized leaf quietly coloured with yellow, and a zone of mixed dark and red; *Unique*, like the last; *Jewell*, like Luna, very neat, small leaf; *Conquest*, a bold style for a pot plant, the leaf large, with a dashing bold zone of chesnut brown; *Canary*, a weak bronzy zone; *Oracle*, small leaf, dark chesnut zone, no character; *Coronet*, large pale green disk, narrow zigzag zone of dark brown.

NEW PLANTS.—In the centre of the exhibition house was a grand trophy-like group of new plants from Messrs. Veitch and Son, of Chelsea, which not only made a beautiful effect, but comprised some subjects of great value and of exquisite beauty. That most beautiful of all known ferns *Leptopteris (Todea) superba* presented its rich dark green plume-like fronds, with the peculiar dripping-wet-like lustre, and elicited rapturous praises from people capable of appreciating such things. *Aralia Veitchii* is exquisitely elegant, and at the same time curious, being of almost wiry tenuity of structure, with a thin tawny stem and slender toothed leaves in sets of twelve around their common axis like the rays of a star. *Nepenthes hybrida maculata*, a dwarf habited pitcher plant with neat pitchers that hang down below the rim of the pot; interesting and beautiful. *Anthurium Scherzerianum*, now well known as one of the most beautiful of stove plants, its large dark green leaves and scarlet inflorescence rendering it eminently attractive and distinct from everything else of its class. *Sanchezia nobilis variegata*, a very fine variegated plant, the leaves pencilled with creamy lines in the most precise manner; as this produces showy flowers it is doubly valuable. *Croton Hookerianum* is quite distinct and splendid in colouring, the large leaves being of a rich lemon yellow towards the base. *Alocasia species (punctatum)* would be an appropriate name for it) has neat leaves, the ground colour of which is light green, with ten large black spots arranged in marginal rows, a stencilled leaf we may say: if adapted to grow as a large specimen it will be one of the most beautiful of exhibition plants. *Begonia Pearcei* is well known and universally admired. *Phormium tenax*, with fine variegation. *Dracena Regina*, quite distinct, compact, and leafy, the young leaves richly variegated with creamy amber. *Maranta Veitchii* and *Maranta rosea-picta* both good. *Testudinaria elephantipes*, not new by any means, yet as it is rarely seen in a presentable state it is proper to chronicle its appearance in this group in a very presentable condition, the huge woody root-stock being surmounted with a vigorous twining stem, bearing abundance of its cordate leaves. *Lomariopsis heteromorpha* is a beautiful climbing fern with pretty bristle-margined pinules. *Retinospora plumosa*, a hardy shrub, with foliage like a glaucous Selaginella. We must omit mention of many other good things in this group, but it is impossible to forget a pair of plants of our good old friend Spirea (Hottea) Japonica, each measuring about a yard over, the leaves a remarkable tint of deep green, the flowers foamy, showy, and in feathery plumes in number beyond counting.—Mr. B. S. Williams, of Holloway, London, was a large contributor of new plants. In this collection we found the beautiful *Trichopilia crispis marginata*, with flowers of a fine deep red colour, margined with a clear white line. *Caladium magnificum*, the leaf medium-sized, and covered with white spots on a ground of pale green. *Dracena nigrescens*, a close habited variety, with leaves of a purplish bronze colour, very nearly black. *Yucca Stokesii*, *Sanchezia nobilis variegata*, *Dracena sanguinea*, elegant in habit, and well adapted for a grand specimen, the leaves narrow, with central line of dull red. *Panicum variegatum*, a pretty grass, with leaves variegated with creamy, rosy, and purplish stripes; it will not be universally admired, yet will in many places become a favourite for decoration. *Coleus Veitchii* does not appear fated to acquire any degree of importance; it is dull and unattractive. *Areca aurea*, a splendid palm of light graceful structure. *Kempferia Roscoeana*, a curious and beautiful plant, showing two suborbiculate leaves of a deep blackish green, richly variegated, and a charming white flower between them. *Adiantum Farleyense*, a true specimen of this glorious fern, with large, deeply fringed pinules.—M. Linden, of Brussels, sent a pretty group of novelties, amongst them *Echites rubro venosa*, with elegant carmine coloured lines on a dark ground, like some of the species of *Anæctochilus*. A fine example of *Dichorisandra undata*, and also of *Maranta Lindenii*, both of them good stove plants, with fine foliage.—Mr. Bull, of King's Road, Chelsea, London, contributed a number of interesting things, and not the least attractive was the curious but almost repulsive *Amorphophallus nobilis*, a drab or snuff-coloured arad, with the spathe unfolding, and displaying a Priapian inflorescence; this was the subject of many inquiries, and in many instances was regarded as a fungus, but its araceous structure was discernible at a glance by those in any degree accustomed to botanical analysis. *Dalechampia Reitziana rosea*, with rosy pink flowers, reminding one at a casual glance of a Bougainvillea.

MISCELLANEOUS PLANTS AND FLOWERS.—There are many subjects deserving of mention for which it is impossible to make separate paragraphs, and perhaps the most important amongst them are the groups of Liliium auratum presented by Mr. B. S. Williams, first, and Mr. John Shaw, second. How Mr. Williams managed to get these to the end of their long journey from Holloway was a mystery, for there was scarcely a scratch upon them, and the flowers were delightfully large and fresh. Mr. Shaw's were fine examples. Cape Heaths were shown in fine condition by Mr. B. S. Williams, Messrs. Cole and Son, and Mr. Shaw. Mr. Kendall took first place amongst amateurs for single specimen. Rhododendrons were few and small, but exceedingly good, especially the two groups of twenty plants from Messrs. G. and W. Yates and Mr. J. Shaw. In the class for ten, Mr. Shaw was first, Messrs. Yates second. Mr. Hodson presented a pretty group in the section for amateurs. There was a class for fifty hardy evergreen trees and shrubs, and a very useful class it was, because of the handsome masses of greenery it brought to relieve the flowers. All the competitors mixed deciduous trees with their collections, and the judges had to consider in the first instance about disqualifying, but on second thought it was determined to judge them all according to merit, and Messrs. G. and W. Yates very properly took first place; Mr. S. Stafford, of Hyde, second. Fuchsias were not plentiful, but Messrs. Balstone, Bindloss, and Chittick brought good groups of pyramids in a well-flowered and fresh condition. Herbaceous Calceolarias were useful, because showy, but they were not quite up to the standard we have become accustomed to, such as that furnished us, for instance, by Mr. James, of Isleworth. Messrs. Tootal, Keymer, and Andrews were the successful amateurs in this class; and to Mr. Keymer was awarded first place in the class for Shrubby Calceolarias.

Of Amaryllis there were two beautiful collections, the best being from Mr. B. S. Williams; the other, a few degrees less brilliant and finished, from Dr. Ainsworth. In Mr. Williams's group were some new varieties, the most remarkable of which were *William Pitt*, fine broad petals, deep orange red shading to crimson, white stripe in the centre of each petal; *Beauté sans Rival*, bright orange scarlet, with greenish stripes, very showy, and a finely-formed flower; *Cleopatra*, rich crimson, with white stripe and white lines, first-rate. There were several collections of fifty each of hardy herbaceous plants, but only one—that from Messrs. Dickson and Brown, of Manchester—was worth serious attention, for the others were brought forward in the dirty careless way which has done so much to defame this class of plants. Messrs. Dickson's specimens were shown in a large box, measuring about 12 feet by 6 feet, neatly surfaced with moss, the specimens fresh and bright, and the names correctly spelt. The plants shown were as follow: *Achillea tomentosa*, *Viola cornuta*, *Saxifraga affinis*, *Myosotis rupicola* (exquisitely beautiful), *Plox frondosa*, *Geranium cinereum*, *Erigeron speciosum*, *Saxifraga rupestris*, *Saxifraga nervosa*, *Dianthus pungens*, *Saponaria ocyroides*, *Linaria alpina* (a lovely gem, fit companion for any alpine *Plox* or *Myosotis*), *Helianthemum canum*, *Phyteuma hemisphaerium*, *Ajuga alpina*, *Iberis Gibraltarica*, *Aquilegia alpina* (most beautiful), *Silene Pennsylvanica*, *Viola lutea*, *Lychnis alpina major*, *Lychnis viscaria splendens*, *Thalictrum aquilegifolium*, *Erigeron grandifolius*, *Lithospermum fruticosum*, *Astragalus hypoglottis*, *Pyrola uniflora*, *Orchis laxifolia*, *Melittis melissophyllum*, *Erinus alpinus* (beautiful), *Silene Zawdski*, *Jasione perenne humilis*, *Dianthus alpinus* (a charming species), *Pinguicula grandiflora*, *Viola pedata*, *Maianthemum bifolium* (a newly-discovered British plant of great beauty; it is like a miniature lily of the valley), *Papaver nudicaule*, *Linum alpinum* (beautiful), *Ornithogalum umbellatum*, *Viola montana*, *Artemisia alpina*, *Arenaria grandiflora*, *Potentilla pyreniaca* (superb yellow flowers), *Astragalus purpurascens*, *Ranondia pyreniaca*, *Saxifraga aquatica*, *Dianthus petraeus*, *Hyacinthus amethystinus*. We should have taken the names all through of all the collections had they been good, but they were not, and we pass them by. The second prize was awarded to Mr. Stafford, the third to Messrs. G. and W. Yates. We wind up this section with a notice of a few pretty varieties of British ferns shown by Messrs. Edwards and Son, nurserymen, of Nuthall, near Nottingham. *Athyrium Filix femina Edwardsii* is a pretty dense-fronded kind, the pinnae overlapping so as to present an imbricated appearance, and the points curl up slightly, so as to give the whole of the frond a crisped character, though in reality it is neither crisped nor tasselled. This is extremely pretty, and well adapted to grow to specimen size for exhibition. *Polystichum angulare rotundatum* is the most distinct of all the varieties of this variable and always beautiful fern, the pinnae being entire and kidney-shaped, and the colour a rich dark green. *Polystichum angulare depauperatum* bears a close resemblance to *Asplenium adiantum nigrum*, and is better than depauperated forms generally are. These three varieties were not the least meritorious amongst the many interesting contributions to this great exhibition, though they occupied a very humble place there. Collectors of choice ferns may safely inquire about them.

FRUIT.—The display of fruit was by no means extensive, and in respect of quantity more could have been desired. But the quality was admirable, and many examples of extraordinary excellence were shown. Messrs. Lane and Son, of Berkhamstead, Herts, maintained their well-earned fame in the exhibition of pot grapes; for not only were there none to equal them, but the best accustomed cultivators and exhibitors agreed in declaring them remarkable alike for superior cultivation and finish, and for perfection altogether unimpaired by long travel. Mr. Statter took the second place. Messrs. Lane and Son again took the lead in the class for orchard-house trees, the specimens shown being in perfect health and covered with fruit. In the class for Pines, Mr. Miller showed a nice Queen, not quite ripe; Captain Glegg, a good Providence; and Mrs. Holland, of Altrincham, a smooth Cayenne. The competition in Grapes was spirited and satisfactory. Best two bunches of Black Hamburg—first (equal), Mr. Meredith, of Garston, near Liverpool, with huge triangular bunches, in a perfect state of finish, and W. Blenkhorn, Esq., with a handsome pair of bunches. Captain Glegg was a good second in this class, for though his bunches were smaller than those placed above him, he had the best finished berries on the table. In the class for best two bunches of any kind of Black Grapes—first, W. Blenkhorn, Esq., with Bidwell's Seedling. This is a variety of Black Prince, said to "supercede Black Prince," which we think open to question. Second, H. J. Hopwood, Esq., with Black Prince; third, the Bishop of Manchester, with Black Prince. Two bunches of Muscat of Alexandria—first, W. Chillock, Esq., of Bowdon, with small bunches, full ripe. In these bunches were a few small berries, indicating unskilful thinning. Second, W. Blenkhorn, Esq., with fine large bunches, wanting ten days to ripen them; third, E. Greaves, Esq., with handsome bunches, rather in advance in respect of ripeness of those to which a second place was awarded. Two bunches of any White Grape—first, W. Blenkhorn, Esq., with beautifully grown and quite ripe bunches of Buckland Sweetwater. Four kinds of grapes, one bunch of each—first, W. Blenkhorn, Esq., with a very nice sample of Buckland Sweetwater, a good Black Prince, a green Muscat of Alexandria, and a good Black Hamburg. The Bishop of Manchester exhibited Muscat Hamburg, Black Hamburg, Black Prince, and White Frontignan. The first prize for six dishes of fruit was awarded to H. J. Hopwood, Esq.; the collection consisted of Buckland Sweetwater and Black Hamburg grapes, a Jamaica pine, *Violette Hative* nectarines, Royal George peaches, and Keen's Seedling strawberries. Six Peaches—first, Mr. Hopwood, with splendid examples of Royal George; second, Duke of Leinster, with Barrington; third, R. O. Leycester, Esq., with *Violette Hative*. Six Nectarines—first, Captain Glegg, with a fine large fruit, like Bowden; second, the Duke of Leinster, with *Violette Hative*; third, Mr. Hopwood, with *Violette Hative*. Strawberries—none worth a first; second, Duke of Leinster, with a good dish of Sir Harry. Mr. Tillery, gardener to the Duke of Portland, at Welbeck, presented a collection, comprising British Queen, La Marguerite, Princess of Wales, Reeves's Eclipse. An interesting collection of grapes was contributed by W. Blenkhorn, Esq., comprising Trentham Black, Black Prince, Muscat of Alexandria, Mill Hill Hamburg, Buckland Sweetwater, Bidwell's Seedling, White Frontignan, Muscat Hamburg, Black Hamburg, Golden Hamburg, and Grizzly Frontignan—all good except the last. Messrs. Brooke and Co., fruiters, of Manchester, covered a table with a beautiful collection, comprising pines, grapes, peaches, nectarines, strawberries, and cherries, all in perfection of size, colour, and finish, the black and white cherries especially being remarkable for their fine quality. Lastly, we noticed as worth a word of praise a dish of York Pippin apples from Mr. Rylance, of Bold Lane

Nursery, near Ormskirk. This is a large round yellow apple, of good keeping qualities; the samples were not in the least shrivelled or discoloured.

There was a great display of greenhouses, implements, boilers, and garden ornaments in the open air. The greenhouses were, generally speaking, complicated and costly things. Jones's Terminal Boiler deservedly attracted attention, as it was shown in parts and also completely fitted, so that its construction and peculiarities could be understood at a glance. This boiler possesses the rare merit of sucking all the heat from the fire, so that it furnishes a maximum of power for a minimum of outlay in respect of fuel. This was exhibited by Mr. Ireland, of Manchester. From Mr. Bennett, of St. Thomas's Buildings, Liverpool, a new telescope syringe, which is an improvement on all ordinary syringes, as it draws and delivers by one and the same stroke, and is worked in precisely the same manner that a telescope is driven into or withdrawn from its tube. From the same exhibitors, a new kind of wire net, called "jointed netting;" this differs from all other kinds in its jointed construction, the separate breadths being loosely locked together, so that it can be rolled up like paper or canvas. If it can be sold cheap enough, it will make a capital trellis for peas, and the best netting for poultry runs, extemporized summer-houses, and for any and every purpose where netting is wanted of a portable nature. Messrs. Hunt and Pickering, of Leicester, made a grand display of their cast-iron portable flower baskets, which are undoubtedly the best things of the kind ever submitted to public notice, as there can be nothing more elegant when fitted up, so when unfitted they can be packed away in a small compass, and weigh only a sixth part of the weight of vases of the same size of any other make. With these many examples of the Leicester garden-seat—elegant, light, cheap, comfortable. These are the sort of inventions to encourage; those that multiply expense and bewilder by complexity are for the fid-fadding people, who like to part with their money for useless toys, and who, probably, will not be turned from their folly by anything we can say; so we will not stop to describe many attractive and costly but comparatively valueless things that were displayed upon the lawn, and that were more or less admired. S. H.

KINGSTON AND SURBITON HORTICULTURAL SOCIETY.

THIRD ANNUAL EXHIBITION, MAY 30 AND 31st.

The managers of this important society were peculiarly fortunate in obtaining the grant of the beautiful grounds of Norbiton Hall for holding the summer show of this season, for the well-known character of the place undoubtedly induced hundreds to visit the show that otherwise would not have done so, had it been held in a less attractive situation; and so far as the number of visitors, and the grandeur of the display provided for them is concerned, it can without question be pronounced a decided success.

STOVE AND GREENHOUSE PLANTS were both plentiful and good. In the class for eight, Mr. Kemp, gardener to Earl Percy, Albury Park, Guildford, first, with a grand lot, comprising fine examples of *Allamanda grandiflora*, *Aphelexis humilis rosea*, *Arpophyllum venosum*, a splendid *Phænomia proliferum Barnesii*, *Stephanotis floribunda* (superbly flowered), and a fine *Leschenaultia biloba major*, and *Genetyllis tuliperum*. Mr. Ransley Tanton, Nurseryman, Epsom, second. Amongst them was a capital plant of *Azalea Eulalie Van Geert*, perfect in shape, and a mass of bloom; a good plant of *Allamanda grandiflora*, not so full of flower as Mr. Kemp's, but the individual blooms much larger; *Clerodendron Balfourii*, *Erica ventricosa carnea*, and *Aphelexis sesamoides*. Messrs. Thomas Jackson and Sons, Nurseryman, Kingston, third, with immense plants of *Eriostemon buxifolium*, *Erica Cavendishii*, *Stephanotis floribunda*, *Epacris grandiflora rubra*, *Hedera tuliperum*, *H. fuchsoides*, *Clerodendron Thomsonæ*, *C. Kæmpferii*, superb in foliage and flower; the plants in this collection were not showy enough, otherwise it must have been placed second, for every plant was a masterpiece of good cultivation. Mr. Gray, gardener to W. Hardman, Esq., Norbiton Hall, Kingston, put up a splendid six, which deservedly obtained the first place, and included a very fine *Azalea Gladstanesii*, *Allamanda nerifolia*, *Aphelexis macrantha purpurea*, *Franciscia latifolia*, and a magnificent *Rhynchospermum jasminoides*.

Good collections of twelve miscellaneous plants in flower were contributed by Mr. Carr, gardener to D. L. Hinds, Esq., The Lodge, Byfleet, Surrey, and Mr. Baxendine, Nurseryman, Guildford. First, Mr. Carr, with *Stephanotis floribunda*, *Clerodendron Balfourii*, *Allamanda nerifolia*, *Rhynchospermum jasminoides* (each seven feet by four, beautifully trained and flowered good plants), *Clerodendron fallax* (seven spikes), *Polygala Dalmaniana*, *Rhododendron Edgeworthii*, and others. Second, Mr. Baxendine, with *Boronia serrulata*, *Coleonema rubra*, *Draconophyllum gracile*, *Pimelea Hendersonii*, *Polygala oppositifolia*, *P. Dalmaniana*, and the curious *Hæmanthus puniceus*, with six heads of bloom.

CAPE HEATHS were particularly good. Messrs. Jackson and Son, first, with the following six: *Florida*, *Candidissima*, *Perspicua nana*, *Ventricosa coccinea minor* (very fine), *Cavendishii*, and *depressa*. Mr. Kemp, gardener to Earl Percy, second, with *Cavendishii ventricosa superba*, *Tricolor Wilsonii*, *Westphaliugii*, and two others. Mr. Baxendine had a good third.

AZALEAS were very good. In the class for six, Mr. Kemp came off victorious with a nice group, containing *Gem*, *Criterion*, *Juliana*, *Beauty of Reigate*. Messrs. Jackson and Son, second in this lot, with a fine plant of Messrs. Jackson's new kind, *Jackson's Grand Crimson*, which is A 1; the flowers are extra stout, immense size, and a deep crimson colour; this variety has the peculiar property of retaining its flowers for an immense length of time, an important consideration to exhibitors of these beautiful plants. For four, Mr. W. Polley, gardener to J. A. Barton, South Bank, Surbiton, first, and Mr. Breach, gardener to W. Home, Esq., Surbiton, second.

ORCHIDS were shown by Messrs. Jackson and Son, Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, and Mr. Dawson, gardener to E. C. Baring, Esq., Kingston Hill. For four, Mr. Dawson had a very fine *Vanda suavis*, with ten beautiful spikes, *Cypripedium barbatum superbum*, and a good *Phalænopsis grandiflora*, not out sufficiently. In the class for six the judges put Messrs. Jackson first, and Mr. Wiggins second, which was evident to any one having any knowledge at all of orchidaceous plants to be wrong; they were both good collections undoubtedly, but taking into consideration the health and rarity of the specimens in Mr. Wiggins's lot,

it is impossible to conceive how they could be placed second; the most charitable construction would be to suppose that they were not judged at all. Messrs. Jackson and Son had *Vanda suavis*, one spike; *Lælia purpurata*, three blooms; *Chysis bracteosa*, two spikes; *Phalænopsis amabilis*, one spike, quite past its best; *Dendrobium densiflorum*, three spikes, and *Cattleya Skinnerii*, four spikes. Mr. Wiggins, *Cypripedium villosum*, *C. hirsutissimum*, large plants and well flowered; *Cattleya Skinnerii*, three spikes, a splendid variety; *Dendrobium densiflorum*, fifteen spikes; *Saccolabium præmorsum*, three spikes; and the scarlet-flowered *Saccolabium minutum* with one spike.

FINE FOLIAGE PLANTS made a grand display. Messrs. Jackson and Son first for eight, with two noble Palms, an immense *Dasyliion*; *Alcacia macrorhiza variegata*, finely variegated; *A. metallica*, superb, and a large *Caladium Chantunii*. Mr. Carr, Byfleet, second, with superb plants of *Spherygna latifolia*, *Croton elegans*, a *Marsanta*, *Alcacia metallica*, and others. Sixes, Mr. Gray first, Mr. Breach second. In Mr. Gray's collection were examples of *Alcacia macrorhiza variegata*, finely variegated; *Croton variegata*, *Cyanophyllum magnificum*, eight feet high, with an immense and beautifully shaped head; *Marsanta zebra*, and a splendid plant of *Chismærops elegans*. Mr. Breach presented good plants of *Pandanus revilis*, *Arslia leptophylla*, *Maranta zebra*, and *Dracæna terminalis*. Some good *Caladiums* were shown, but as the collection containing the finest varieties and best grown plants, twice the size of those in either of the other lots, were put second, the less said about them the better. Ferns, both British and Exotic, were exhibited in great abundance. In the class for eight Exotics, Messrs. Jackson and Son first, with *Todea Africana* (fine), *Angiopteris evecta*, a remarkably fine plant of *Gleichenia hestiochylla*, *Lomaria gibbs*, *Gleichenia vestita* (an immense plant), *Asplenium furcstum*, and *Neopteris stipitatum* (with immense fronds). Mr. Carr, second, with some very good plants; conspicuous were *Gymnogramma chysophylla aurea*, the beautiful *Nephrodium molle corymbifera*, and *Nephrolepis davallioides*. Third, Mr. Gray, with well grown healthy plants of *Pteris argyrea*, *Asplenium nidus-svis*, a magnificent *Adiantum cuneatum*, and a fine *Calypteris proliferum*. The same remarks will apply to the six exotics as used for the *Caladiums*, the ferns being rather the worst of the two. For twelve British, Mr. Morse, Epsom, first, with a capital lot. Prominent were *Osmunda regalis cristata*, *Lastrea Filix mas Moreri*, and *Polypodium alpestre*. Second, Mr. Carr, who had a remarkably good specimen of *Adiantum capillus veneris*. Third, Mr. Kemp. For nines, first, Mr. Crofton, gardener to A. Marshall, Esq., Kingston Hill, with a fine lot; Mr. Baileys, gardener to the Rev. E. Phillips, with a good second.

PELARGONIUMS.—Mr. Wiggins made a grand display with his leviathan plants, the nine occupying the whole of one end of the tent, and, as they thoroughly deserved, received the first prize, the varieties being, *Maid of Honour*, *Princess of Denmark*, *Royalty*, *Flambeau*, *Cynosure*, *Pericles*, *Alba regina*, *Aimée*, and *Regina formosa*. Six, first to Mr. Head, gardener to F. A. Du Croz, Esq., of Kingston Hill. For nine Fancies: first, Mr. James, gardener to W. F. Watson, Esq., Isleworth; second, Mr. Wiggins. In the collection of fancies, the sorts were principally *Godfrey Turner*, *Cloth-of-Silver*, *Arabella Goddard*, *Ame*, *Rosabel*, *Roi des Fantaisies*. Six fancies: Messrs. Dobson, Isleworth, first, and Mr. Turner second, with fine collections.

FUCHSIAS.—Several good collections were staged. Mr. M'Phearson, gardener to A. Allenby, Esq., Surbiton, was first, with six really good plants; each stood about 8 feet high, perfect pyramids, and loaded with flowers from the base to the apex, the sorts being, *Wiltshire Lass*, *La Crinoline*, *Rifleman*, *Venus de Medicis*, *Rose of Castile*, *Souvenir de Chiswick*; Mr. James, Isleworth, second. In another class for six, Mr. Smith, gardener to W. F. Hoare, Esq., Marlborough House, Kingston, first; Mr. Crofton, second.

Good collections of *Achimenes* and *Gloxinias* were contributed by Mr. Gray and Mr. M'Phearson; variegated and zonal geraniums by Mr. Lowman, gardener to W. Hannay, Esq., Norbiton, and others. Two splendid sixes of herbaceous calceolarias were exhibited by Mr. James, gardener to W. F. Watson, Esq., Isleworth (fine); and Messrs. Dobson, Isleworth, second; Mr. M'Phearson, third, with good plants, though not so large as the other collections. Mr. R. Tanton, first, with three tastefully arranged hanging baskets.

In the FRUIT tent Messrs. Jackson and Son, first, in the collection of eight dishes, with very fine grapes, Sir Charles Napier strawberries, and cherries. Mr. Pople, West Moulsey, first, for dish of black grapes; second, Mr. Rowe, Roehampton; both dishes were fine examples of grape growing, large, well-shouldered bunches, and of first-rate colour. Dish of white grapes: first, Mr. Rowe; second, Mr. Gray, who was first with peaches and nectarines; Mr. Davis, Roehampton, second for the former. Mr. Smith first in all four classes for melons. Capital strawberries were contributed by Messrs. Gray and Breach. The best pine in the tent was disqualified, the other two being so dead ripe, like East Indian pines in appearance, that because this pine was quite fresh and plump, the majority of the judges, with an unaccountable ignorance of what really constituted a good pine, supposed it to be unripe, and a part of a pine took its place, it being destitute of its top. They appear to be determined to have everything at its full maturity, otherwise the first prize for a brace of black spine cucumbers would have been awarded to Mr. M'Phearson instead of Mr. Penfold. Mr. M'Phearson's brace were several inches larger, fine deep colour, and much less in circumference than the others. The dozen cut roses which stood second must be noticed. The schedule states that they must be distinct, whereas this lot was one kind only, and ready to fall to pieces, yet obtained a second. Why were they not disqualified as the rules require?

A very important feature in the exhibition was the dinner table decorations, competed for by ladies only, the competition being very spirited both for the Society's special prize and that offered by the President (W. Hardman, Esq.). Hand bouquets were poor, with the exception of a very tastefully-arranged one exhibited by Mrs. Gordon, The Elms, Hampton Wick. A fine *Monstera deliciosa* was exhibited in fruit by Mr. Hills, gardener to H. Western, Esq., Berwood, Horsham, and a fine bunch of *Musa paradisiaca*. The roses in pots must not be forgotten. Several collections were shown. First for six, Mr. Polley, gardener to G. A. Barton, Esq., Surbiton; second, Mr. James, single specimen; both foliage and flowers were good. For flower: Mr. Gray, first, with an immense plant of *Aphelaxis macrantha purpurea*, four feet through, and a mass of flower. For foliage: Mr. Crofton, first, with a splendid specimen of *Dicksonia antarctica*. A much better appearance was given to the stages by using tape to separate the different collection

instead of chalk as in former years, through a suggestion made in this paper. The different arrangements reflect much credit upon the Secretary, Mr. Kirk, and his assistant, and it is much to be regretted that it has been necessary to call attention to other unsatisfactory points in the course of the report.

WEST LONDON ROSE SHOW.

This exhibition took place at Ealing, on Tuesday last. We regret we cannot speak of it as a decided success, but it was carried out with much spirit, and there were some very good roses, and some excellent collections of plants and fruits shown. It appears that a paper circulating in the district threw cold water on it, and created a prejudice against it, and the promoters were badly supported in consequence. We hope they will have the courage to live down such opposition, and enter upon the undertaking next year with the same or even with increased zeal, and they may be sure they will succeed, for a good flower-show is one of the best of entertainments, not only for horticulturists, but for the general public. Twenty-four cut roses, first, Mr. James, gardener to W. F. Watson, Esq., Isleworth, with *Bronne Prevost*, *Joseph Fiala*, *Madame Charles Verdier*, *Maréchal Vaillaot*, *Madame Boll*, *Princess of Wales*, *Gloire de Dijon*, *Madame Charles Wood*, *Lælia*, *Colonel de Rougemont*, *Prince Csmille de Rohan*, *François Lacharme*, *Souvenir de la Malmaison*, *Paul de la Meillerez*, *Eugène Appert*, *Madame Alfred de Rougemont*, *La Fontaine*, *John Hopper*, *Thomas Rivers*, *Pierre Notting*, *Charles Lefebvre*, *Jules Margottin*, *Monte Christo*, *Céline Forestier*. Second, Mr. Marlow, gardener to J. Wigan, Esq., Mortlake, with *Sénateur Vaisse*, *Maurice Bernardin*, *Rev. H. Dombrain*, *Madame Falcot*, *Elizabeth Vignerot*, *Lord Clyde*, *Model of Perfection*, *Princess of Wales*, *Souvenir de la Malmaison*, *Prince Camille de Rohan*, *Madame de St. Joseph*, *Madame Victor Verdier*, *Baronne Prevost*, *Géant des Batailles*, *Mademoiselle Emain*, *Alex. Fontaine*, *Souvenir d'un Ami*, *Souvenir d'Elise Vardon*, *François Lacharme*, *Gloire de Dijon*, *Mrs. W. Paul*, *Madame Damsizin*, *Charles Lefebvre*, *Comtesse Chabriland*. Mr. W. Soden, gardener to C. Hanbury, junor, Esq., of Brentwood, presented a pretty box of twenty-four. In the class for twelve, first, Mr. W. Soden, with *Madame Willermoz*, *Charles Lefebvre*, *Madame Amelia H. Iphen*, *Princess of Wales*, *Rubens*, *Victor Verdier*, *Jules Margottin*, *Louise Van Houtte*, *General Jacqueminot*, *Gloire de Dijon*, *John Hopper*, *Madame Yeatman*. The first prize for the best twelve Tea and Noisette roses, was awarded to Mr. George Marlow, whose flowers were *Madame Damaizin*, *Julie Mansais*, *Clara Sylvain*, *Souvenir d'un Ami*, *Gloire de Dijon*, *Rubens*, *Goubault*, *Comtesse Ovaroff*, *Madame de St. Joseph*, *Madame Willermoz*, *Madame Falcot*, *Madame Brvy*. In the class for new roses of 1865 and 1866, Mr. Marlow was placed first with *Duchesse de Medina Cœi*, *Dennis Helye*, *Charles Margottin*, *President Mas*, *Madame Fillion*, and *Charles Wood*. The best bouquet of roses came from Mr. Marlow, second, Mr. W. Soden. There was a pretty group of plants in flower, comprising pelargoniums, fuchsias, &c., from Mr. H. Brunell, East Acton. Some good samples of fruit were shown by Mr. A. Fraser, nurseryman, of Aylesbury, Bucks, and Mr. T. Humby, gardener to W. Jupp, Esq., Old Brentford. Mr. Fraser also contributed good samples of English grown lemons and oranges.

NOTES OF A TOUR THROUGH KENT.

HENSTED PARK, THE SEAT OF THE RIGHT HON. GATHORNE HARDY.

I visited this very superior residence on Saturday, May 11th, in company with a respected friend and correspondent, Mr. J. Staply, to whom I am indebted for the pleasure of a delightful morning walk through a beautiful wooded portion of the above estate, which lay in our way towards the mansion. We entered the grounds by a private entrance on the Cranbrook Road, and at once made our way to the kitchen gardens, where we were soon introduced to Mr. Stalker, the head gardener, who, with the usual frankness and courtesy that it has been my good fortune to meet with everywhere, kindly consented to show us everything that would be likely to amuse us or please us. We at once set out towards the more ornamental portion of the property. In leaving the kitchen garden by a rustic gateway, we at once enter into a delightful portion of the pleasure grounds, with noble and stately trees dotted here and there, and luxuriant banks of shrubs. Standing, as we do now, upon elevated ground, and catching, at every few paces we make, between fine belts of shrubs, views of the distant country, the spot becomes most enchanting; for the more immediate surroundings are diversified by hill and dale, while away farther in the distance, as far as the eye can reach, the scene is one of unusual splendour, with rich and charming valleys and fertile fields, and bold and striking woodland banks, lighting up the scene, until the eye rests with delight upon the distant Kentish bills. But if I enjoyed this view, which I did amazingly, how much more did I enjoy the one from the opposite side of the park from here, where the view, for a broad expanse of country, is second to none I have yet seen in this part of England! But I must not attempt a description further than to say it was rich in subjects and glorious in extent, for as the eye gathered in its focus the more immediate objects, it became a vast panorama of majestic splendour, while the distant objects blended with richness upon the horizon.

Turning our attention now towards the mansion, we find it an imposing and noble structure, surrounded by a well-timbered and an extensive park, while the surrounding country is rich in woodland scenes and luxuriant corn-fields. And in coming again to the private portions of the grounds, we find them designed with taste and in the best of keeping, with a noble conservatory in excellent order, and gay with some choice and good subjects, and a few good ferns in excellent condition, such as *Adiantum cucullatum*, and the old Stag's Horn fern of monster size. I noted also two artificial vases or stands, exquisitely and most tastefully arranged with the more hardy exotic ferns and mosses. Then there were very large specimen plants of the *Aphelaxis macrantha purpurea*, and a host of other subjects, all in such excellent condition as to furnish a ready key to the industry and intelligence of the directing mind.

In the forcing department we saw in the way of plants a choice collection of *Caladiums*, such as *Bellemeys* and others; also a superb collection of ferns, chiefly exotic, as well as some useful ornamental foliage plants. Mr. Stalker had also secured an excellent strain of herbaceous calceolarias from Messrs. Downie, Laird, and Laing. They were superb varieties, both in form and colour. The majority of calceolarias I have seen this season have been so poor and destitute of form, that I consider this case deserving of a remark.

A, Section of cucumber house. B, Strawberry pit. C, Pier of garden wall. D, Boiler. E, Walk. F F, Flue. G, Ground level of house. G G, Ground line.

There is here a continuous range of five vineries. In the early house the first crop was fast colouring, and of a uniform size both in bunch and berry; in the second vinery the crop was equally good, as well as remarkably clean and healthy, and the same remark applies to the other houses. In the third vinery I noticed a fine lot of succession pines for autumn and winter fruiting. In the fruiting pine-stove there was an excellent show of fruit in various stages; and in an adjoining house running parallel to this was a good assortment of generally useful plants for conservatory decoration. Of melons, the Scarlet Gem was swelling off a fine crop of fruit, and successional crops were making good growths, as also were cucumbers in the same range of pits.

I give here a sketch of the end section of the cucumber house, now under repair; also end section of an adjoining range of pits, with the position of the boiler. I do so chiefly to show our young readers how a chimney in connection with the boiler has been dispensed with, as in this particular position the sight of a chimney would be objectionable, and how by a clever contrivance the difficulty was got over. As will be seen, the flue is carried from the boiler (outside), but just under the ground, a little below the ground-level of the houses. The distance from the boiler to the pier of the garden-wall, as shown, is about 24 feet. The flue is then carried up in the pier of the wall, so that no chimney is visible.

As a closing remark, I must just refer to the excellent condition of the bedding plants, which were here in great number and stout sturdy stock. On the walls I noticed excellent crops of both peaches and nectarines, and other fruits.

J. C. CLARKE.

A SELECTION OF VEGETABLES, WITH HINTS ON THEIR CULTURE.

The season is fast approaching when every gardener who cultivates a kitchen garden will be anxious, as each plot of ground becomes cleared of the summer crops, to fill up the same with those plants that are needed to supply the kitchen with vegetables during the winter and early spring months. To those who have not a yard of ground too much for complying with the requirements of the household, we would say—and especially to young gardeners so situated—do not, by way of experiment, attempt to plant too many plants of any kind of vegetable with the habits and productive qualities of which you are not well acquainted. The descriptions of new things in the seedsmen's catalogues may be correct, but then situation, soil, and other collateral circumstances may not be favourable to their yielding properties, so that with such varieties it is best to only plant a small breadth, and thus test their worth, with a view to their adoption, if desirable, in future seasons. I have often thought, in the desire to avail ourselves of favourable weather for planting, when we have had a piece of ground vacant, that we have not always well thought over the arrangements of our crops previous to planting. I have seen a border alongside of a wall, to some extent, planted entirely with Brussels sprouts and other kinds of vegetables of a robust constitution. This practice is decidedly wrong in principle, because such vegetables are gross feeders on the soil, and grow very rapidly in moist seasons, thus depriving the ground on which they are planted of a deal of its nourishing materials, and proving injurious to the trees which are planted against the wall, so that it is no matter of surprise to witness the inferior and scrubby growth presented by many of the trees planted against walls in various parts of the country. This, I am certain on investigation, may be traced to the cropping of the border year after year with luxurious-growing vegetables. As these borders are generally formed with a gradual slope towards the pathway, they thus quickly and naturally drain themselves in wet weather. This, then, is an advantage which is favourable to the preservation of the dwarfed kinds of vegetable products, which are so liable in cold wet soils to canker or rot off in the stem during the winter months, such as lettuce, endive, &c. If necessity compels you to use the

fruit borders for the growth of the larger sorts, then let your selection be confined to the dwarf and more tender varieties of broccolis. Where you are somewhat pressed for space during the earlier period of planting, it is better to always prick out a few over the required number of each kind of plants into nursery beds as soon as they are fit, as by such practice you are enabled to wait a little longer time, till in due order your summer crops are all cleared away, because the operation of planting them first in nursery beds keeps them dwarf and robust, whereas, if allowed to remain in the seed bed till the period of planting commences, they in many instances become tall and weak, and very many of the broccoli plants will become blind; besides, it encourages the formation of club roots. Although this practice entails on us a little extra trouble at a very busy season of the year, yet we are more than twofold repaid in the future.

We cannot, where we are expected to furnish the table with plenty of greens during the winter, do better than plant plenty of that very hardy borecole the Cottager's Kail. It thrives well if planted between the rows of dwarf trees, such as gooseberries, currants, &c. Then again, of that old popular variety known as Scotch kail, the tall kind is the best. When planted out rather early, it will produce some extraordinary heads, which are very acceptable to cut from in severe frosty weather, after which their strong stalks will yield an abundance of sprouts till late in the spring, if needed. These are the only two varieties among the list of hardy kails that I would recommend for general culture.

Brussels Sprouts.—Not half enough of this delicious but profitable vegetable is cultivated in our gardens. Their hardy constitution makes them very desirable. Their heads are about their tenderest part as regards constitution, and should be cut in the earlier part of the winter months, as wet and frost cause them very often to rot. The Roseberry variety is a very tall grower, and a great favourite with me on account of the abundance of sprouts it yields. Though some of the dwarfed kinds afford very large and compact sprouts, yet the former for general use is the most preferable where space is limited. Many when gathering the sprouts are apt to tear them off, or rather pick them with the thumb and finger. Now, if you wish for a continuous supply of sprouts from the same plants, you may ensure them if, when gathering, you cut them off with the knife, leaving as much of the stalk of the sprout as it will give. By this means you will have three or four sprouts instead of one as originally. This vegetable is always acceptable at table on account of its delicious flavour.

Of *Broccolis* there are but very few, in regard to quality and hardiness, to surpass many of the older varieties that have been familiar to our gardens for more than one generation. It is true that in the extreme southern parts of England many of the newest sorts attain the very highest state of perfection to which the broccoli can be grown. Yet, where we have no ground to afford for experiment, let us still confine our planting to such kinds as the Brimstone or Portsmouth for early spring use. Knight's Protecting is a very hardy sort, requiring less room for its growth than the former. Then Grange's Early White Cape is a very valuable broccoli, as in favourable seasons it will continue to produce nice heads till Christmas. There is another good hardy sort which no winter, however severe, will destroy; that is Miller's Dwarf Hardy. This does not require more room than a foot from plant to plant, and they produce nice white heads late in the spring. The principal objection to this variety is that nearly all the heads are fit at one time for table, so that it is a waste of ground to plant many. But for market growers the ripening of the whole crop at one time is perhaps an advantage. We must not forget that very useful broccoli the Purple Sprouting, and the old established variety of this is far better than a few new ones that have been described as superseding it.

JOHN F. M'ELROY.

PARIS UNIVERSAL EXHIBITION, 1867.

(From our own Correspondent.)

No. III.

I continue to attend flower shows until I am giddy and weary, but more than all, distressed that I cannot send you reports worth printing. The fact is, looking sharp as you do after English exhibitions, you really don't need to be kept strictly informed about French ones, for they are inferior to such as we are accustomed to in England, and furnish but few useful suggestions to experienced habitués of floral gatherings. Before I sat down to summarize what I had seen at exhibitions lately, I turned aside instead into the department of silks and silk fabrics (Group IV., class 31), where I spent the whole of yesterday making a careful study of the numerous and valuable examples of dressed and undressed silks. To tell you that the Italians and the Christian inhabitants of the Turkish dominions show themselves to be expert in the cultivation of silk would be superfluous information, and I might be reminded that the subject was just beyond the domain of horticulture. But I must tell you I have seen samples of the silk from the Ailanthus worm and the Japanese oak-worm, in the collections from Signor Filippi of Clavesana, and in the collections from Gallizia of Turin, Bozetti of Milan, Conti of Milan, and P. Gavazzi, who was one of the first to encourage the introduction of the new silk-producing moths into Italy. I should probably have made some very learned notes about these things, but I happened to fall into conversation with M. M. Palluat and Piquefen on the subject, and as we were all in a rather mutually communicative and inquiring mood, I told them I was anxious to know something about the produce of the new worms, the more especially as there was a bit of a rage for their cultivation in England. I will not pain those of your readers who believe in the Ailanthus silkworm by repeating any of the deprecatory language employed by these practical men, when informed that English cultivators of silk were still hopeful as to ultimate results. We got very warm upon this subject at last, and gathered a few statistics from head-quarters, and found that in the best

can get fruit, whereas, the most fruit-loving birds will quit the orchards and settle amongst the silkworms; and it costs as much as all the silk is worth to keep the birds in check. In every respect, then, these worms are unfitted for the English climate, and the profitable cultivation of silk in England must be looked upon as an impossibility. A Mr. Mason, of Farnborough, has sent a nice sample of English grown silk; it has been very skilfully prepared for exhibition.

I could repeat all the praises I have lavished on the gardening at the Exhibition. Billancourt is a dead failure; not so the gardens in the park, and the reserve garden, and the central garden, which are all now in beautiful trim, and present the most varied scenes and effects. No English horticulturist possessed of catholic tastes will regret a visit to our great Exposition, if it be only to see the plantations and rockeries, and other special features illustrative of horticulture proper, and of landscape gardening. I have made a sketch of the central, or inner garden, to give you some idea of the style in which this is embellished, and which you will observe is in the so-called "sub-tropical" manner. They have new planted out in this favoured spot, which is sheltered from wind on every side, quantities of Yuccas, Cannas, Dracenas, Caladiums, Wigandias, and Ricinus, with things yet more choice than those, extending even to big Palu-trees, and other of the most costly fine foliage subjects. The colouring is quiet but rich, but it is to form they have trusted most for that artistic repose and refinement which is essential to the scene, and which I am happy to say has been perfectly secured.

That you may not conclude me to be idle, I must tell you that I went to the Imperial farms to witness the trial of mowing machines, and only failed to report thereon because there was no trial; the weather was bad, and the grass quite unfit. "Grass," I say, but I mean weeds. I could not see any grass, but plenty of docks, dandelions, and nettles. I am told that the trial will take place in earnest shortly, but I simply don't believe it; but if it does happen, it can be of no use, for the ground is quite unfit, and the competition will be tame. If any betting takes place—and the French let me tell you, are becoming as fond of betting as the English, and, therefore,

PARIS UNIVERSAL EXHIBITION, 1867.—THE CENTRAL GARDEN.

parts of Italy the produce of the Ailanthus worm in the very best seasons had not exceeded in value at the rate of 20s. sterling of English money per English acre. M. Barré, who joined our party soon after the conversation began, jocosely suggested that the worms ought to be waterproof for the English climate, and with great *éclat* pronounced it needful they should wind off their own cocoons. Having had some practical experience in silkworm culture, I was not at all surprised to hear that the cocoon of the Ailanthus worm is a troublesome thing to deal with, and requires an altogether different treatment to that adopted in winding off the mulberry worm. The vice of the Ailanthus worm is that it does not spin a continuous thread. As to the success of this worm in England, you will be able to form some idea when I tell you that the most experienced silk growers consider the climate of the south of France and Italy not good enough for it. Last year was a very bad year, but 1865 was good. The worms are heavy, sluggish, helpless things, and during stormy weather they get blown or washed off the trees, and never get up again. M. Dumas, who travels much as a buyer of silk, assures me that he has solemnly made up his mind not to buy any of the alanthus or oak-worm silks until the last hank of mulberry silk is sold; for, says he, with a shrug of the shoulders, "I do not buy silk for myself, but to sell again, and these coarse silks are unfit for any market but such as fools assemble in." A curious circumstance in connexion with the introduction of these worms is, that their very existence is in a great measure dependent on the extermination of birds, and it is the preservation of birds that observers in natural history, together with all farmers and gardeners, are interested in. Wherever these new worms are grown birds must be kept down by poison, trap, and gun, for they find out the plantations and swarm to them to gobble up the fat lazy caterpillars to become fat and lazy themselves. Here is a new argument, however, to hurl at those thick-headed people who insist that birds will not touch insects while they

as likely soon to come to ruin—I shall back Wood's American machine against all others with a certainty of winning. I have paid some attention to the grasses which prevail in pastures and lawns, and I think I may venture to say that the French are in just about the same phase of undeveloped Acrostography as we were before Sinclair began his grass garden at Woburn; when, in fact, one kind of grass was supposed to be as good as another, and poisonous herbs were cut with the swathe, and no one thought it a matter of much consequence if half the field consisted of hemlock or ranunculus. There are good pastures to be sure, but not yet can it be said, respecting the growth of grasses and the making of hay, "they do these things better in France," for the truth is they don't, nay, nor a third part so well.

METEOROLOGY FOR MAY.—(Pencailland, East Lothian, N.B., 284 feet above sea level.)—Therm.: max. 70°; min. 25°; range, 45°. Sol. max., 82°. Grass therm. 21°. Barom.: high. 30.02; low. 29.25; range, 00.77 inches.

Rain-fall, 2.03; in 1866, 1.10; in 1865, 5.60; in 1864, 2.10; in 1863, 1.40; in 1862, 3.17; in 1861, 0.80; in 1860, 0.60 inches.

On the 14th, the min. therm. stood at 25°, being 7° of frost; and the grass therm. 21°, 11° of frost. Considerable damage to vegetation; potatoes blackened, bursting buds on beech hedge and fern leaves killed, shoots on the pines nipped. The centre of the bloom of the strawberry blackened, and a great deal of damage to geraniums and other plants in the bedding-out garden. 21st: Hail showers, and on the Lammermuir Hills, highest point 1,716 feet, snow fell sufficiently to indicate its very distant.

Tyneholm, June 4, 1867.

TREVELYAN, J. P.

SOME BEAUTIFUL TREES AT BEAUPORT, THE SEAT OF J. BRASSEY, ESQ., NEAR BATTLE.

Beauport, the seat of the late Sir Charles Lamh, is so well known in the horticultural world as offering attractions of a superior order to lovers of beautiful trees, that the mention of the place will revive to many pleasing reminiscences. It is pretty generally known that the late worthy and enthusiastic proprietor not only devoted much of his leisure time, but also expended yearly large sums of money on the embellishment of the park and grounds with all the rare and beautiful trees that were introduced to this country.

It was to inspect these grounds, and collect at the same time some notes and information of this extensive collection of hardy trees, that I specially made my way to Hastings, and from thence to Beauport, which lies about midway between Hastings and the ancient town of Battle. On arriving at the mansion, Mr. M'Bean, the intelligent foreman (who, I may take the liberty to state, has been there thirty years), kindly offered to show me all I desired to see; and in drawing upon my notes I shall take them in the order they were made on the spot.

Starting from the steps of the flower garden, on the eastward front of the mansion, a glorious scene presents itself—a fine open space of ample width, looking through a mighty bower of large trees down far away into the distant valley, with various tints of foliage of extraordinary cheerfulness and variety. Such a scene cannot be met with in any other part of England. As we stand here admiring the many magnificent specimens of choice and beautiful trees within view, and the changing and ever-varied hues of the different varieties of foliage, we lift the eye to scan the distant country, when in the distance we observe the sea-shore, known on that part of the coast as Dungeness. From this same point, too, there is on a clear day a fair view of the coast of France. The scene here is indeed a rich one for those who can appreciate perfect harmony and judicious planting. The many beautiful combinations secured on this lovely spot, by the exercise of skill and taste in arranging the various trees and shrubs which make up the scene, speak much for the good taste and superior foresight of the designer. To give the reader an idea how varied are the effects, and how valuable the collection, I will now notice some of the subjects which especially interested me. On the left, about twenty yards from where we stood, were two magnificent specimens of the Cedar of Lebanon, *Cedrus Libani*, and next these, in the same line, was a noble *Cedrus Deodara*; the dimensions of the *Deodara* are as follow: height 46 ft., diameter of branches 36 ft., girth at three feet high 6 ft. 2 in. These trees are hacked by a variegated plane and other large trees, such as oaks and heeches, towering far above them. Following up these two lines on either side by well-defined outlines, there are Irish yews, arbor-vites, rhododendrons, and the graceful single pink and double flowering thorns, *Crataegus oxyacantha* vars. in abundance. Farther on, as the distance increases from the house, is a grand scarlet-flowering chesnut, *Aesculus rubicunda*, standing out boldly in the foreground, and making quite a striking feature, giving variety and character to the scene. This spot is still more enriched by the graceful drooping branches of a copper beech, *Fagus sylvatica cuprea*, hard by; while on the opposite side are good examples of *Cupressus* in variety, some from 9 ft. to 10 ft. high. The background to these extends far away in the distance, increasing in beauty and adding variety to the scene. Leaving this spot, and turning our footsteps in a more northern direction, we come upon another superb *Deodar*, 46 ft. high. Near this, and in a most luxuriant condition, is the Swiss Stone Pine, *Pinus cembra*, with its almost scarlet-like flowers at the base of the new growth peeping up in the most erect manner above the foliage, giving a very pleasing effect; this plant is 30 ft. high, and 3 ft. 6 in. girth. Of *Cupressus torulosa* there are but few to compete with the many large plants here. I noticed one especially, before we had gone far into the park, over 20 ft. high, a noble plant. Of weeping subjects perhaps the most graceful and effective were the silver birches, *Betula alba pendula*, as they stood on the edge of a charming dell; or as some more noble and favoured tree stood out with plenty of space for extension, their slender branches dipped gently down in most graceful attitudes, presenting a fine contrast to the more rigid and formal characters of our English oak. Then there was that majestic-growing subject the *Pinus ponderosa*, 36 ft. high. Of the superior specimens of *Pinus Douglasii*, which are here in strong force, the following dimensions of the largest tree will give the reader an idea of their imposing character: height 66 ft. 6 in., girth 6 ft., diameter of branches 39 ft.

Of *Araucaria imbricata* there are some of the finest in the kingdom, and in such numbers as I have not yet anywhere else met with, as there are no less than three hundred, averaging from 14 ft. to 40 ft. in height, the highest plant being 41 ft. in height. I thought this one a superb specimen, as it was very evenly furnished from top to bottom, but soon after I lighted upon another, the stem of which could not be seen at ten paces from the tree except about two feet of the leader at the top; from this point down to the ground the branches were so dense and symmetrical in outline that not a particle of stem was visible. This specimen is 38 ft. 6 in. high, girth 4 ft. 1 in. at three feet from the ground, diameter of branches 23 ft. For beautiful outline and density of growth this tree surpassed all the rest. I met with that scarce variety also here, *Araucaria lanceolata* (or *Cunninghamii*, as it is sometimes called), but it was evidently not at home here, as it is in a very sickly state, which was quite an exceptional case, as I saw nothing else but what was most vigorous and healthy, which speaks wonders for the fertility of the land, as the fact that everything here escaped the severity of last winter's frost does for the suitability of the position for valuable and somewhat tender trees. But the distant reader must not be misled by these statements, because the grounds of Beauport are perhaps the most favourably situated of any in this country for the growth and cultivation of all choice hardy plants, and more especially those of doubtful hardiness, standing as it does (about midway) on a ridge of hills that extends itself to the eastward down to the sea-coast, and to the west on to the town of Battle; it enjoys such an immunity from all impure atmospheric influences as to render it at once the position of all others that would be likely to be conducive to a vigorous and healthy vegetation. This fact, taken in connexion with the statement above made, that the soil is of a fertile character, and naturally well drained, must prepare our readers for the success that has attended the cultivation of the trees here named.

Referring again to my notes, I have *Pinus Nordmanniana*, a beautiful subject for a prominent position; the specimen under notice is 30 ft. 6 in. high, girth 2 ft. 6 in., diameter of branches 14 ft. Then we have another magnificent subject, the *Cupressus macrocarpa*, upwards of 50 ft. high.

This was a striking feature, and the best specimen I have yet seen. Of *Wellingtonia gigantea* there were many excellent plants, the largest measuring 23 ft. 6 in. in height, girth 3 ft. 5 in., diameter of branches 25 ft. This was 2 ft. high when planted in 1859. The rate of growth of the leader, therefore, must have been about 3 ft. annually. The next six are 18 ft. in height, from which they vary down to some considerably smaller. I noted also that fast-growing conifer *Pinus Menziesii*. This was 64 ft. 6 in. high, but straggling in habit. There was also here another *Pinus Douglasii*, towering up to the height of 66 ft.; this is a grand and an imposing tree. One of the best habited *Pinus insignis* I have ever seen is here, standing in the grounds near the carriage entrance to the house; its height is 37 ft., girth 6 ft. 5 in., diameter of branches 40 ft. It was planted in 1840, and was then 6 in. high. Near here was the beautiful fern-leaved beech, *Fagus sylvatica heterophylla*, and many other choice and rare things, including some fine varieties of rhododendrons, araucarias, copper heeches, the flowering ash (*Ornus Europaea* and *O. Americana*), and a host of other equally interesting subjects. There, too, was *Abies Braziliense*, close and compact, 5 ft. high; and also *Pinus morinda* (*Abies Smithiana*, *A. Kurotzu*), 36 ft. high, in fine condition, as was also *Cryptomeria Japonica*, better than usually seen. The height of this plant is 29 ft., diameter of branches 25 feet, girth 3 ft. 6 in. The greatest curiosity amongst deciduous trees is a marvellous fern-leaved oak, *Quercus filicifolia*; it has been planted twenty years, and has only grown to the height of 5 ft.; the diameter of the branches does not exceed 10 ft., and the girth 6 in., with a flat top in the form of a bush. In this part of the grounds the most telling subject, as looked upon from the distance, is the noble pine, *Pinus nobilis*. It is dense in habit, dark in foliage, with an erect and noble bearing, and altogether a magnificent plant; its height is 32 ft. 6 in., girth 2 ft. 7 in., diameter of branches 13 ft. Near here was also *Picea Cephalonica*, towering up to the height of 29 ft., while a little farther to the right is *Pinus Webbiana*, with its young dark purple cones peeping up erect above the leaves. This is a superb species, very effective and grand in its bearing, and worthy of extensive cultivation where trees of character are required; the height of the plant under notice is 26 ft. 7 in., girth 3 ft. 2 in., diameter of branches 18 ft.

In the above list I have only attempted to notice some of the most effective and largest trees that are to be seen here, as there is perhaps a larger collection of hardy trees and shrubs in this place than in any other private garden in this country. When I say the largest, I mean principally of the more choice and rare kinds; and these, he it remembered, are so judiciously distributed, that any one going with a view to see them finds that the interest never flags, for in every part of these extensive grounds we were ever and anon coming upon something curious or rare or beautiful. But the time is at hand when this extensive and valuable collection of trees will require the attention of some interested person, as the beauties of many of them are already partially shut out from view by the surrounding trees and undergrowth, and as these were evidently planted with a view to shelter and protect the more choice ones, the time is coming when they will require to be gradually taken away, to give room for the fast extending branches of the many beautiful trees with which this place abounds; and sincerely do I hope that the litigation in which the estate, I am told, is involved, may not be the means of preventing this being done. So great was the love of trees in the mind of the late Sir Charles Lamh, that every available position is occupied with them; indeed, to such an extent, that the disposition of the ground cannot now be seen to advantage, and the character of the park, as a natural consequence, is becoming heavy and monotonous; the open glades and green slopes are hidden from view. There is a great want of relief from the overpowering richness of the planting, and it is only at wide distances that the beautiful fertile valley below can be seen.

I truly enjoyed the few hours I spent in this beautiful park, and there was only one circumstance which tended in any way to mar our pleasure, and that was the absence of the respected head-gardener, Mr. Streeton, who is busily engaged superintending the making of a new garden some four miles distant, where the present occupier of Beauport, J. Brassey, Esq., has bought a new estate, but which time did not permit me to visit, though I hope some day to do so, and report. J. C. CLARKE.

ON THE ORIGIN OF TRICOLOR-LEAVED PELARGONIUMS.

PAPER READ BY MR. GRIEVE, GARDENER AT CULFORD HALL, NEAR BURY ST. EDMUND'S, AT THE SCIENTIFIC MEETING OF THE ROYAL HORTICULTURAL SOCIETY, MAY 21.

The cause or causes of variegation in the leaves of plants, including, of course, the pelargonium, are as yet, I believe, unknown; consequently, no means could be successfully used to produce it; but when from some unknown cause it spontaneously developed itself in an individual plant, then in accordance with the law or doctrine of hereditary transmission of qualities, little difficulty is experienced in inducing it to reproduce itself in succeeding generations.

The chemical or other changes, however, which must take place in a plant to induce its foliage to become variegated, present undoubtedly a very interesting subject for inquiry, and one worthy, it may be supposed, of the attention of the vegetable physiologists. I have at different times consulted various authorities upon this subject, without, however, being much enlightened thereby. Doctor Hope says:—"That there is in plants a colourable principle consisting of two separate parts, one of which forms a red compound with acids, while the other forms a yellow with alkalies." And he attributes the green colour produced by the latter to the mixture of the yellow matter with the blue infusion. The two principles, according to him, may exist together or separate, in different parts of the same plant.

Dr. Balfour also says:—"The whitish or brown spots which occur on the leaves are often produced by thickened cells containing peculiar colouring matter underlying the chlorophyll cells. In such cases variegations might be traced to an alteration in the epidermal cells, and the same is true of certain bright colours assumed by the surface of some leaves."

With regard to the leaf of the tricoloured pelargonium I have sometimes been inclined to think that the zone undergoes no change whatever when the leaf becomes variegated, or yellow margined, and notwithstanding the fact of red being one of the primary colours, consequently, according to theory, cannot be produced by any combination of colours. But covering, as the zone does, the junction of the yellow margin with the green disk, or centre of the leaf, we find that whatever part of the zone rests upon the yellow appears bright red, while the portion which may rest upon the

green part of the leaf retains its normal or brown colour. The question now is, how is this red colour produced? For my own part, I too hastily jumped at the conclusion that the brown and yellow had produced the red; but this, according to the theory of colour, could not have been the case. So I must leave the settlement of this interesting question to those whose scientific knowledge may qualify them for the task.

Before proceeding to what was intended to have been the principal part of this paper—viz., the furnishing what little information I could as to the history of the tricolored Pelargoniums—I may notice a defect incidental to the Silver tricolored section, but without being able, I am sorry to say, to suggest a remedy. I alluded to the cupping, or crumpling of the foliage, more particularly when the varieties are cultivated in the open air, and if the weather is at all cold and wet. This crumpling appears to be caused by the fact of the white or colourless margins being unable to expand in proportion to the growth of the green, or central part of the leaf, consequently cupping or crumpling is inevitable; and very possibly this deficiency of expansive power in the white margins of the leaves may be attributed to the nearly entire absence of chlorophyl, or the green colouring matter; and that this defect does not in any way apply to the yellow-margined varieties may be accounted for by the fact that their yellow margins are not entirely destitute of this principle.

Some twenty years ago there were, I believe, but few varieties of variegated Pelargoniums in existence. Of these the two best fitted for the purpose of bedding or massing in the flower garden were a sort known as Variegated Nosegay, and another called Mangles' Variegated Nosegay. Of the origin of the first named I know nothing. Of the latter I have heard that it was obtained by the late Captain Mangles as a sport from a green-leaved variety. This sport is well adapted for the purpose of bedding, and is still, I believe, extensively used for that purpose. The two varieties named above were both silver-margined sorts, with Nosegay, or very narrow-petalled flowers. The only golden-margined sort of any merit was the variety known as Golden Chain, and of its origin I am also quite ignorant, but I have been informed by an old gardener that he recollected having grown it along with a collection of stove plants nearly fifty years ago.

But somewhere about seventeen or eighteen years since the horticultural world was somewhat startled by the announcement of a Scarlet Pelargonium, having broad-petalled flowers and variegated foliage. This proved to be the celebrated and now well-known variety called Flower of the Day, and I believe that we are indebted to Mr. Kinghorn for the introduction of this forerunner of a highly ornamental race of plants. This variety was soon followed by others of increased merit, the production, I believe, of more than one successful raiser, amongst which the names of Lennox, Elphinstone, &c., deserve to be mentioned.

Amongst these new introductions the beauty of several varieties was greatly enhanced by having, in addition to their silver margins, a well-defined red or pink zone, well defined and exceedingly beautiful when the leaves were in the early stages of their development.

These varieties, combining as they certainly did three distinct colours in their foliage, may with propriety be designated as the forerunners of the silver tricoloured race. And to Mr. Kinghorn, I believe, belongs the credit of having originated the first of them, and the variety was, I think, named Attraction.

About the year 1855 or 1856 I had succeeded in originating several varieties which were considered as advances on their predecessors, the best of which, however, was the variety named Italia Unità, which in its class is perhaps unsurpassed. And about the time stated above it occurred to me that similar improvement might possibly be effected in the golden-margined varieties, which at that time consisted only of Golden Chain, and I think one or two other sorts inferior to the sort named. But at all events I confined my experiments to the variety I have named (Golden Chain), and after trying many experiments, many of them resulting in failures, I at last succeeded in originating two varieties which were considered as worthy of being distributed under the names of Golden Tom Thumb and Golden Cerise Unique.

These were succeeded by Gold Pheasant, which was also in its turn eclipsed by the variety known by the name of Sunset. And in the following year I succeeded in raising the now well known variety, Mrs. Pollock, which was succeeded by Mrs. Benyon, Lucy Grieve, and lastly Lady Cullum, which is now being distributed by the Messrs. Henderson, and about which variety it is quite unnecessary to say that it will be sure to prove a public favourite. The great desideratum in a variegated pelargonium is a vigorous constitution, and consequently the power of rapid increase by cuttings. And this quality is possessed in an eminent degree by the variety last named, and in a still greater degree by the variety which I had named Queen Victoria, which I consider to be in all respects the best I have ever raised, and on that account took the liberty of giving to it the name of her gracious Majesty. But since doing so I find that I have been forestalled, as the name appears to have been already assigned to another variety; but I think that I may still adhere to the name in the slightly altered form of Victoria Regina.

Soon after the introduction of the variety named Mrs. Pollock, the attention of other cross-breeders appears to have been directed to this subject, and the consequence is that the number of tricolored pelargoniums may now be said to be legion; and growers have ample opportunities of selecting and adding to their collections varieties of the greatest merit, including, of course, habit of growth, quality of bloom, &c.

I have recently given the pedigree of the variety Mrs. Pollock. All the Golden Tricolor Pelargoniums which I have originated have descended from Golden Chain. I have also at various times tried sundry experiments with the variety called Mangles' Variegated Nosegay, without having been very successful. It is a sort which did not produce pollen freely, nor did it seed freely when fertilised by the pollen of other varieties; and even when it does appear to ripen seeds, they very frequently refuse to grow. I have, however, succeeded in raising a few seedlings from it, and one of them is known as Stella variegata, and was produced between a seedling Nosegay variety (raised from a very strong growing sort known as Mrs. Vernon), and Mangles' Variegated Nosegay. This variety (Stella variegata), greatly resembles sports which have at different times, and in various localities, been obtained from Beaton's Stella, although their origin, as I have endeavoured to show, is entirely distinct, and their flowers, it will also be observed, are of a different shade of colour.

Last year I fertilized blooms of a small-leaved seedling Nosegay sort, with well-defined zones, and which has been named Blackband, with pollen taken from Stella variegata, and one of the results is the Minimum variety, with very white leaf margins, which has been named Minnie Warren.

Some years since, on the introduction of some of the better sorts of the white-flowered zonal varieties, such as Madame Vaucher, White Tom Thumb, &c., all kinds having well-defined zones, it occurred to me that if sorts with foliage similar to Mrs. Pollock, Lucy Grieve, &c., could be induced to produce pure white flowers, that it would be a very desirable acquisition. And I immediately set about experimenting in the matter, but found the process to be much slower than I had at first calculated upon; and I fear that if I were to attempt to describe all my experiments and failures, that it would justly entitle my paper to be considered as tedious and lengthy, if it be not already entitled to that distinction. But suffice it to say, that in four generations I succeeded in producing plants having golden tricolored foliage, and also in producing pure white flowers, but unfortunately accompanied by an exceedingly feeble constitution, and apparently a strong determination to leave this world as soon as they conveniently could, and which most of them succeeded in doing; still I managed at the same time to persuade a few of them to live, and one of them is now before you; it is named The Ghost, as it is only the ghost of what I wished it to be. But the first two points had been gained, viz., tricolored foliage and white flowers; and the third point only is wanting, and that is vigour of constitution; and the first step towards that point is, I believe, successfully taken, and the proof of which is now before you in the variety named Eva Fish.

Two principles, it will be observed, had been active in tending to enfeeble or debilitate the constitutions of the white-flowered and golden tricolor race; that is, variegation itself, which always tends to diminish the vigour of any variety; and also what is called the "in and in" system of breeding, which is known to have a similar effect in the vegetable as well as in the animal kingdom. And the method I have adopted to throw fresh blood, as it were, into the race is as follows, and as far as I can judge at present, I think that it is likely to prove successful:—

I selected one or two strong-growing, silver-margined seedlings, having very light pink, or nearly white flowers; these I fertilised with pollen taken from Madame Vaucher, White Tom Thumb, and some other green-leaved, white-flowering sorts. Most of the progeny proved green-leaved; a few, however, showed variegation; but I selected a few of those which showed no symptoms of variegation whatever, and when they bloomed they nearly all proved to have white flowers, and these I fertilised with pollen taken from the variety named The Ghost; and the result of this cross is the plant named Eva Fish, and one or two other promising seedlings, which I have little doubt will produce white flowers.

It would appear that because the hand of Science has not directed such experiments as I have endeavoured to record above, scientific men hardly feel inclined to assign to the rough and ready cross-breeder the amount of credit which he may possibly consider as due to his exertions. Professor Morren, in treating upon this subject, says that the cause that operates in the production of such varieties as Mrs. Pollock, Sunset, &c., is a multiple or complex one; and draws attention to the apparent diversity of the origin of such plants, and to the simultaneous appearance of similar forms in different localities in England, in France, and in Belgium. Now, all this I believe to be incorrect, and to be an instance of conclusions being arrived at without trouble having previously been taken to ascertain the facts. I believe, in common with most growers and raisers of these plants, that no Golden Tricolored Pelargonium deserving of the name existed antecedent to Mrs. Pollock and Sunset; and if any similar varieties originated simultaneously, either in this country or on the Continent, let me ask where they are to be found, or what has become of them? M. Morren further says:—"These varieties are not the result more or less directly of man's agency, nor of this or that operation of the cultivator, but they are the indirect but inevitable natural and spontaneous consequences of the mode of development belonging to the species when grown under artificial circumstances, &c." Possibly we may be told some day that St. Paul's Cathedral was a spontaneous production, independent of man's agency, &c.; and some, perhaps, may be found to believe it.

For my own part, I believe that the pelargonium is grown at present under much the same artificial circumstances as it was grown a hundred, or, possibly, two hundred years ago; and our great-grandfathers might have enjoyed the luxury of hedging-out tricolored pelargoniums in the summer of 1767 in precisely the same way as their descendants are doing at the present time, had their tastes led them in that direction, and if the idea had occurred to them to use the means at their command.

As I have said before, I believe that the cause of variegation is unknown, and consequently cannot be produced; and the cross-breeder does not for a moment presume to say that he can control Nature. All that he can do is to watch her closely, and when he perceives her in the least degree inclined to tread the path he wishes her to pursue, he can as it were smooth that path and render it as inviting as possible. He may, perhaps, even go a little further, and policeman-like touch her gently on the shoulder, and respectfully request her to move on. More than this he cannot do, for what the poet has said with regard to nature's fairest production will also apply to nature herself—

"For if she will, she will, you may depend on't;
And if she won't, she won't; so there's an end on't."

I have stated that the pedigree of the pelargonium Mrs. Pollock has been made public. But as some who may read this paper may not recollect the particulars, the seed parent of Mrs. Pollock was Emperor of the French, and the pollen parent Gold Pheasant. The seed parent of Gold Pheasant was also Emperor of the French, and the pollen parent Golden Tom Thumb. The seed parent of Golden Tom Thumb was Cottage Maid, and the pollen parent Golden Chain.

As to the parentage of some of my seedlings of the present and last years, I am unable to give any information, as in most instances both parents were themselves seedlings, and many of them have not been preserved.

MUSHROOM GROWING IN LIGHT OR DARKNESS.

The quality of the forced or artificially produced article is very inferior, indeed, to the natural production from the pasture and the sheep-walk. The former is generally brown, hard, and leathery; the latter snowy white, soft, and crisp. It lacks, too, the delicate pink colour of the gills and fragrance characteristic of the field mushroom. As to flavour and digestibility, we will not institute a comparison. We are told to study nature, because nature is a friend to truth. Do we do this in the cultivation of the mushroom? Are we altogether right in consigning the mushroom bed to the dark shed or cellar? or still further excluding light by the conventional covering of straw or musty hay—the latter, at least, neither adding

to the flavour or aroma of the produce? Who in quest of the genuine wholesome article would go seek for our favourite *Agaric* in the dark shade, or among the long, dank grass? Would he not, even if found in such a situation, reject it, and turn his steps to the comparatively bare upland pasture, or still more closely-cropped sheep-walk, fully exposed to all the vivifying influences of air, heat, and light? The best forced crop of mushrooms we ever saw was at a place in a southern county. The shed was made quite flat on the floor of a shed, the roof of which had a very small pitch, and supported only by a couple of slight iron columns. The shed was also fully exposed on two sides; consequently there was abundance of air and light. At the time we saw it the shed was without any covering whatever, but we cannot say, for we did not inquire, if it had been always so. Again, the most extraordinary crop of field mushrooms, as well as the most beautiful in appearance, and doubtless delicious in flavour, we ever met with was on a very elevated plateau in the Co. Wicklow, more than ordinarily exposed to all those influences from which we take pains to exclude our artificial plateaux for the growth of this much-prized esculent. Is our practice of the exclusion of light, and growing them in dark sheds or cellars, merely conventional, because they will grow without the former, and in any out-of-the-way place like the latter? We rather think it is. In the absence of that all-important element, and in such places, they can, as said before, be produced in quantity, but—and this is the point we venture to throw out for the consideration and test of our practical friends—subjected to the influence of light and the situation improved, would not perchance the quality be also improved, so as to approximate more closely to that of the delicious produce of our pastures? Even as regards quantity of produce, there may be some doubts of the correctness of our practice; for though darkness is generally favourable to the growth or extension of the mycelium of fungi, it is by no means so to the development of their fructification. We may be wrong, but one day or other cheap glass and double glazing, we fancy, will do something in improving the quality of forced mushrooms.—*Irish Farmer's Gazette.*

GRASS "IMMORTElLES."

The now important and still rapidly increasing demand for winter floral decorations has not only led to great improvement in the manufacture of artificial flowers, but has also given rise to the extensive sale of "immortelle bouquets," in which the dried flowers of *Helichrysums*, *Xeranthemums*, *Gnaphaliums*, and other so-called everlasting, are largely supplemented, and their sameness agreeably relieved, by tastefully introduced spikes and culms of grasses, many of which are, from their beauty and delicacy of structure, highly available for such a purpose. Their producers, or caterers for the market demand, have, from the want of sufficient variety in their colours, been led to attempt their improvement by means of artificial dyes, which in many instances are far from being either tastefully selected or applied. Dyed wool and artificially-coloured feathers have been looked upon as being in unison with correct ornamental taste, from very early times, and we may have no right to find fault therewith, provided the colouring be well applied and permanent in its endurance. Nor do we mean to disparage the colouring of immortelles, provided it be effected with sufficient care and a reasonable regard to the observance of nature's laws, which seldom distribute the same colours over flowers and flower-stalks, and never without accompanying them with a beautiful shading off and blending with those of the still more remote stems, whereas all our artificially-coloured flowers, grasses, and even mosses, present disagreeably decided markings of the dip into the dye-pot. "Whatever is worth doing at all is worth doing well," is a truism which our "immortelle" dyers seem to ignore, or at least disregard; but they will do well to take care in time, or their craft may be endangered by that unpopular but highly artistic class of colourists, the clover-seed dyers, who are now threatened to be deprived of their dishonest vocation; for assuredly they, who possess the ingenuity requisite for imparting several beautifully blended shades of colour to a small speck like a clover-seed, will find little difficulty in adapting their skill to the more legitimate calling of flower-dying.

It is commonly remarked that coloured grass-heads never present that purity and delicacy in their tints which is so conspicuous in coloured feathers; this is, no doubt, chiefly, if not entirely, in consequence of the pure white ground on which, in the latter case, the colours are laid; whereas in the more common grasses the ground or basis for the artificial colouring is generally dark green, more or less shaded with purple. With white-headed grasses, such as the feather grass, *Stipa pennata*, and the first introduced variety of the pampas grass, *Gynerium argenteum*, purity in colouring is easily effected, but it is very different with many of the other favourite bouquet sorts, such as the *Aira caespitosa* and other hair-grasses; the two native soft grasses, *Holcus mollis* and *H. lanatus*; *Poa trivialis*, and other meadow grasses; the elegant annual and perennial quaking grasses; the delicately paniced family of *Agrostidae*; the magnificent reed tribe, *Arundineae*; the pretty melic grasses; the robust but graceful brome grasses, and others, the ordinary forms of all of which have the ground colours too dull or dark for taking on pure dyes, unless such as are of the darker tints. To a certain extent this imperfection in their grounds may be overcome by bleaching, but only in most instances at the risk or certainty of destroying that beauty of structure which has recommended them for selection. Most grasses have, however, like other plants, their albinos or white-flowering varieties, in which the colours of the plants are lightish green, while to that of their inflorescence the term *whitish* is strictly applicable; and these have only to be selected with discriminating care, propagated by division, and cultivated to a sufficient extent, to supply all that is desiderated both in quality and quantity. Among common grasses these albinos are perhaps most frequent in *Poa trivialis*, *Holcus lanatus*, and *Aira caespitosa*, but a demand has only to be created for them when they will soon be forthcoming of any other species; and we would specially advise those having opportunity to look out for a white-flowering variety of the common reed, *Phragmites communis*, on the muddy shores of rivers and fresh-water lakes, the discoverer of which will be rewarded by possessing a perfectly hardy grass, equal in elegance and beauty to either the somewhat tender South-American pampas grass, *Gynerium argenteum*, or the famous *Tobi-tobi* or *Toe-toe* reed of New Zealand, *Arundo conspicua*.

Large sums of money are now annually expended on the importation of grass immortelles, the production of which could be equally as well, if not better, done at home—for the delicate ramifications and elegance of structure, in the paniced grasses more particularly, render them very susceptible of injury from packing and long transit. Here, then, is a new branch

of industry specially suited for females—the wives and daughters of gardeners for instance—and which for its establishment would only require a little initiative example and support at the hands of any willing to undertake such a labour of love, aided perhaps by a little stimulating encouragement from city and village horticultural societies. Flower culture has of late been largely superseded, or rather greatly supplemented, by fern culture, and why should not grass culture have its turn of popularity? Assuredly a little minute examination and acquaintance with the beauty, delicacy, and diversity of their forms should secure for them a fair share of cultural care from all plant lovers who can spare a small space, either in the open ground or in pots, for their occupation.—*The Farmer.*

Calendar.

WORK FOR WEEK COMMENCING JUNE 15.

Kitchen Garden and Frame Ground.

CELERY.—The early crops to be earthed up as soon as the plants have attained a good size. If the ground is dry, give a heavy soaking of water the day before intending to mould them, and be careful that the soil is nearly dry, or at most only moderately moist, when the moulding is to be done.

CABBAGE.—If there are any vacant plots of ground, and no occasion to crop them with successional summer vegetables, it will be advisable to sow good breadths of *Early York*, *Rosette Colewort*, and *Dwarf Early York* cabbages. These will come into use in advance of the ordinary winter greens, and will be very acceptable.

BROCCOLI.—The last sowing of *Walcheren* may be made this week. Any plants remaining in seed-beds must be planted out at once where they are to remain.

BROAD BEANS may be sown for late supply.

RUNNER BEANS sown now will give supplies late in autumn, when the peas and early-sown beans are gone. We have for several years past sown on the 20th of June or thereabout, and found the result most satisfactory.

LETTUCE.—It is a good plan to sow some quick-germinating kinds, such as *Wheeler's Tom Thumb*, where they are to remain, as the operation of transplanting tends to cause them to "bolt." Dig and manure the ground, and sow thin in drills a foot apart. As soon as large enough to handle, thin them to six inches apart. Begin to draw for use as soon as they show a tendency to bearing, which will give more room to those that remain. Lettuces to be transplanted from seed-beds now should have a very rich soil, and if possible a shady position, and abundance of water. If they can be kept from bolting, they will form fine hearts very quickly. The best preventive of bolting is to keep them growing fast, and manure, moisture, and shade are favourable agencies.

LEeks to be planted out from seed-beds on deep rich soil; on dry stony ground they should be put into well-manured trenches in the same style as celery, but on ordinary good soils it is better to plant them on the level, as they stand the winter better. A convenient mode for earthing up is to plant them in four-foot beds, six rows in a bed, the plants six inches apart.

PEAS.—To get good late crops it is advisable to sow in well-manured trenches six inches below the general level, as in case of drought the trenches can be filled with water quickly, and will keep all that is given them. The principal enemy of late-sown peas is mildew, the result of a starved condition of the plants. Peas advancing in growth should be staked in good time; if they once fall over, they can never be got up again to do as well as they should. Watering peas, as a rule, is objectionable, and if they are on ground deeply dug and liberally manured—and it is mere vexation to attempt to grow peas on poor ground, or ground badly prepared—they will not want water.

TURNSIPS must be sown now, as there will be a demand for them soon. Use abundance of manure; sow if possible just before rain occurs, or between flying showers.

ENDIVE to be sown on rich soil, and early sown to be planted out.

CUCUMBERS in frames often show a stubbornness in swelling off their fruit, though apparently full of health and vigour. Very often a good soaking at the root will cure all this. Cucumber plants may be and often are kept alive by the syringe merely, but they want soaking to be fruitful. Where the plants are still pushing, and are full of vigour, put on about two inches of fresh soil. In the case of cucumbers that have grown large, and there is likelihood of waste, half a fruit may be cut, and the other half left on the vine. The half left will continue to grow, and may be cut when wanted. This is a better way than waiting half a cucumber.

WINTER GREENS to be got out in plenty now, as peas, potatoes, and other crops are taken off. Collards, Brussels sprouts, and other quick-growing subjects that will mostly be used before Christmas, to be planted in manured ground; but those to stand till next spring, to furnish sprouts, not to be manured, as it renders them less able to withstand severe frosts. Continue to plant broccoli, Brussels sprouts, Scotch kale, and everything else of the kind from the seed-beds.

GARDEN VERMIN.—The rains have favoured slugs and snails, but of caterpillars there is happily a scarcity this season. The vermin that can be most successfully combated are snails, woodlice, and ants. The first two are destructive marauders; the last is rather troublesome than destructive, though they destroy sometimes—as, for example, when they construct a nest in a seed-bed, and bury the young plants in mounds of fine earth, or when they take possession of a frame in which a number of cuttings have been bedded out. Three years ago we lost four-fifths of a batch of rose cuttings by the mining operations of a colony of ants. The batch consisted of about 3,000 cuttings, and the operations of the ants commenced just when the roses were forming their first roots, and when we were beginning to leave them to take care of themselves, having removed the lights to expose them to the showers. Let us consider the snails and woodlice first, and add as a make-weight earwigs. The grand preventive of all these is active tillage of the ground. Neglect of any kind is favourable to their increase. They are sure to multiply where there are heaps of rubbish, rank crops of weeds, fences unclipped, and dirty holes and corners. The frequent use of the hoe, the immediate clearing off of crops that have had their day (whether vegetables or flowers), and the manuring and planting of the ground with successions, will do wonders to check the depredations.

tions of vermin. Every disturbance of the soil exposes them and their eggs and young to influences detrimental to their increase, not the least among those being the keen eyes of birds, kept vigilant by the calls of hunger. Frequent dressing of the surface soil with lime and soot will do wonders, both to kill the vermin and produce a healthy vegetation. We do indeed see lime used so freely sometimes that it must kill the plants as well as the snails; but we do not advise the wasteful and destructive use of so powerful an agent. A sprinkling which suffices to make a barely perceptible gray coating on the soil is as effectual as a heavy dressing, and the repetition of the thin dressing will in time bring the whole piece into so clean a state that vermin will be virtually unknown. We come next to consider special means of eradication, and these are many. Trapping should be followed up in a systematic manner wherever vermin abound. Small heaps of brewer's grains will draw snails together in a most convenient way for killing them. Lettuce-leaves placed under empty flower-pots will collect the woodlice in dozens or hundreds, and while they can get lettuce they will not care to eat anything else. Slices of potato, carrot, and apple are also good baits. Moreover, any dry and dark hiding places soon get filled with woodlice, and a dose of boiling water poured into such dens daily, without disturbing the materials of which the dens consist, will clear them off wholesale. The writer of this has waged war in all sorts of ways with these plagues for many years, having valuable collections of plants in a garden which is surrounded with breeding grounds for all sorts of vermin. Among other methods adopted, one is to put a few empty pots one inside the other, in cucumber frames, and every morning to pour boiling water into them. The water soaks into the bed, and does no harm if near the woodwork, and when the pots are shaken asunder dozens of dead woodlice are found. But another and more systematic plan is adopted, and, having proved eminently successful, we advise any of our readers who are situated as we are to proceed as follows: Procure a portable copper—that is to say, one of those “iron coppers” which are made for boiling water in the open air for tea-parties, and which are often used in out-houses by laundresses. Londoners can find such in Barbican and Old Street, and the prices range from thirty shillings to three or four pounds each. Suppose a border, in which asters, stocks, phloxes, and pentstemons are planted, and in the rear of the border an old privet hedge, out of which the vermin issue in swarms. Such, indeed, is the nature of our border on which the operation is conducted. In the front of this border a number of small flower-pots are plunged to the rim. Every evening these pots are filled with lettuce-leaves, pea-shells, slices of cucumber, or whatever tempting stuff is at hand. The pots are then covered with cabbage-leaves or tufts of moss, with, in short, anything through which woodlice can push or a snail eat its way. Every morning a fire is lighted with garden rubbish, such as *débris* of woodstack, &c., and a few gallons of water are obtained boiling hot. A dose of this is poured from a water-pot into each of the traps. In the evening the traps are cleared out and filled again, and so on for ever. This appears a tedious process, but without it we should have to relinquish horticulture under our present circumstances. We adopted the “iron copper” to make an end of the diurnal row between the gardener and the cook, the latter refusing the thermal element, or because of the demand made upon her putting the *cuisine hors de combat*. Now for the ants. If the nests are so situated that boiling water can be administered, why the remedy is easy enough. It is very seldom, however, that this can be done, for in the first place the water cannot be obtained, or the nests are in places where the destruction of vegetation by the process could not be borne. It is not generally known that fresh Peruvian guano will drive ants from any spot, however firm a hold they may have obtained upon it. Suppose a colony of ants to be commencing operations on a lawn, it is an easy matter to trap them all by placing a large empty flower-pot, with the hole stopped, over it. The ants will build up into the pots, and in a short time it may be lifted with a shovel and he carried away and dropped into a vessel of water, which will make an end of it. When they make a run up the stem of a fruit tree, a line of gas tar all round will put a stop to their progress, and do no harm to the tree. To poison them, mix arsenic with sugar and water, put the mixture in a saucer, and lay a slate over it, and on the slate a stone. This, of course, is a dangerous plan, and any one who thinks of adopting it must use their own judgment as to the safety of any larger animals. In Jones's “Gardener's Receipt Book” it is said that ants will avoid any tree which has a circle of chalk round it. Having never made use of chalk to check their movements, we cannot say if this be true. Lastly, as to earwigs, any dry dark trap will take them, such as stems of the elder-tree from which the pith has been removed, four-inch lengths of bean-stalks, or the dried stems of the great Heraclium, or bits of paper crumpled in the hand and tucked amongst the plants they infest.

Flower Garden.

HARDY BULBS, such as hyacinths, tulips, snowdrops, crocuses, &c., may be taken up and stored away. Where planted in a mixed arrangement, and the ground need not be disturbed, it is a good plan to allow all these bulbs to remain two or three years in the ground.

ASTERS AND STOCKS to be planted out from pots and seed-pans during moist weather.

DAHLIAS to be staked at once, if not already attended to, and the forwardest shoots to be carefully tied.

ROSES are in most districts infested by grub and fly. Heavy rains will do them more good than any kind of artificial watering. The removal of the grubs that curl the leaves and gnaw out the hearts of the buds is usually accomplished by hand-picking—that is, when accomplished at all; and it is such a tedious job, that nine-tenths of all the rose-growers leave the trees to fight it out. Probably the “Aphis-wash” of the City Soap Company, which is so immediately effectual in the destruction of fly, would be equally destructive of these grubs. We advise rosarians to give it a fair trial. Pot roses must have abundance of water now.

CHRYSANTHEMUMS must be made to grow freely now, or it is impossible they should bloom well. Give abundance of water. Where quantities are required for plunging or other rough purposes, it is a good plan to plant them out on an open sunny spot, and take them up early in October, and pot them for flowering. But genuine specimens cannot be obtained in this way: they must be grown in pots from the first. Chrysanthemums in the open ground to be topped again, and the soil between them lightly pricked over with a small fork, and some quite rotten dung worked in. It will be found that they always root near the surface, and a dressing of dung will greatly help them, and save the labour of watering.

LILIUMS to have abundance of water.

CALLA ÆTHIOPICA is an aquatic, but is usually grown as if it was un-

acquainted with water. We shall see everywhere, now especially, in nurseries and great gardens the plants standing on coal-ashes, and getting a daily drop of water in common with other things. By this treatment they flower once a year. We have some that were potted on in very rich unctuous loam, after their spring flowering was over, and then plunged in water, one inch deep, out of doors. They have grown prodigiously, and are now flowering profusely.

BEDDING GERANIUMS should be propagated at once for next year, and the best way is to use cuttings only two or three joints in length, and pot them singly in 60-sized pots. By being struck early, there is time for the plants to make ripe wood before winter, and instead of waiting till July for bloom, they will, if well managed, be in full bloom in May next, when first planted out.

TALL-GROWING BEDDERS need a little care now to protect them from high winds. A very effectual and expeditious method is to insert strong stakes, and run a few lengths of stout tarred string amongst them, so as to form a support to the back and front of every row. Small forked branches will serve the same purpose where the plants are not sufficiently regular to be supported with string.

Fruit Garden and Orchard House.

PLUM-TREES in orchard-houses are in many cases covered with fly. If this is not checked, the trees will be barren next season. Make a strong infusion of tobacco, and at the same time dissolve a little glue; mix them together, and add water in a large tub, and into the mixture dip the trees. Any that are too large to be dipped must be laid on their sides and well syringed. Those dipped must also be syringed the next day. If the labour can be found, it will be more effectual to paint with a soft brush every leaf, under and upper side, with a mixture of one pound of dissolved glue, one pound of tobacco, and four gallons of water. The leaves will appear after the operation as if varnished, but not a leaf will fall, and it will make an end of the vermin. After a few days, syringe them freely.

EGGS producing a second crop to be fed liberally, and have a top-dressing of quite rotten dung. The top growth must be pinched back.

Greenhouse and Conservatory.

CAMELLIAS showing their flower-buds at the points of the new shoots should have more air and less water. The syringe need not be used any more upon them, but they ought never to go dry at the root, for that is a sure way to cause the buds to fall.

PELARGONIUMS as they go out of bloom to be cut down, and placed in a warm, sheltered, and rather shady place for a week, then to be put in the full sun and kept rather dry at the root, with occasional sprinklings of the stems and leaves till they break, and then to be re-potted back into small pots with sound lumpy turf to make their new roots in.

CINERARIAS coming up in seed-pans to be pricked out as soon as large enough to lift, and have separate thumb-pots, with light rich compost, and be put in a frame to grow on. By securing a vigorous growth from the first, they will be less troubled with fly, and make fine specimens. Those who have not sown seed yet must do so at once, or it will be too late.

HARD-WOODED PLANTS requiring a shift this season must have it at once, or the time will go by for them to derive full benefit from the operation. The most important matter of all is to secure good drainage and to use the compost in as rough a state as possible consistent with the size and nature of the plant. Whenever the cultivator is in doubt about the best soil for any hard-wooded plant, he will be pretty safe in using half peat and half loam, both in a turfy and sweet condition—the more elastic the better.

FUCHSIAS must be syringed twice a day, and have moderate shade. Fine plants in comparatively small pots will be greatly benefited with weak liquid manure every three or four days. They should be propagated now in quantity for next year's supply. The smallest cuttings make the best plants, and there is no need to cut to a joint. A mild bottom-heat will hasten the formation of roots, but it is not needful, as if shut up in a cold frame, and shaded and regularly kept sprinkled, they will be well rooted in a fortnight. It is a saving of time in the end to put all cuttings singly in pots at this time of year, as they can be allowed to fill the first pots with roots, so as to grow strong from their first start. In preparing pots for the cuttings, use smallest sixties or thumbs; put a mixture of turf and old dung over the crocks, and fill up with half sand and half leaf, in which the cuttings will root as quickly as in sand alone at this season, and have something to live upon while filling the pots with roots. This is the best method for amateurs who are much away from home, as the single cuttings require less care than when dibbled into sand only in shallow pans.

ERICAS.—At this time of year it is usual to overhaul the heath house and make notes of losses and of desiderata, and to shift specimens and put in cuttings of choice kinds, as well as prepare composts for future use. The heath is a native of the Cape of Good Hope, where it clothes the sides and tops of mountains, and springs out of the crevices of rocks, growing in very sandy soil, such as, in this country, we call peat, and is found on our dry heaths, where our native ling grows. One of the first things, then, for the intending heath-grower to do is to select a stock of soil, and having looked out a spot where it is black and unctuous-looking, with a good sprinkling of clear bright sand sparkling in it, he may proceed to clear off the rough herbage that grows upon it—for the heath is generally found where the ling grows strongest; then to pare off the surface only a few inches thick, and avoid the poor, gray, hungry soil that lies beneath. The supply should be renewed every year or two, for if kept too long it loses its fibrous texture, and is then only fit for very small stock from the seed-pan or cutting-pot. For larger plants, soil somewhat fresh and lumpy is best. Some peat is wanting in due proportion of clear white sand. This may be corrected by the addition of silver sand, and this should be done upon the potting-bench, as some of the free-growing, soft varieties, such as *Bowieana*, *cruenta*, *exurgens*, *flammea*, *refulgens*, *Willmoriana*, *intermedia*, *metulæflora*, *verticillata*, *Bergiana*, *cupressina*, *gracilis*, *grandinosa*, *hyemalis*, *Linneana*, *pyramidalis*, *sulphurea*, &c., being the hardest and most suitable for beginners, will flourish best in a peat not very sandy; whilst the very hard-wooded, or delicate growing varieties, such as *Hartnelli*, *ampullacea*, *aristata*, *elegans*, *Massoni*, *Templeana*, *tricolor*, *vestita*, *Sprengelii*, *gemmifera*, &c., though very beautiful, are more difficult to cultivate, and require a larger proportion of silver sand in the soil. It may be necessary to caution the inexperienced against falling into an error we have known amateurs to commit, viz., the mistaking bog soil, met with in swamps and by river-sides, for the peat soil above described; for no composition, however carefully prepared, can enter into competition with

pure native peat soil for hesth-growing houses. As the heaths delight in a cool airy house, they must not be associated with such soft-wooded plants as pelargoniums, cinerarias, &c., but must either have a house to themselves or have for their associates other hard-wooded plants which will bear the treatment the heath requires. In the latter case, a low span-roof house, with side-lights to open, or with ventilators instead, and with slate benches or beds of gravel, upon which the plants stand cool, and are not so subject to alterations of temperature and moisture as they are upon spline stages, and in "pitched" or "lean-to" houses, is the kind of place in which the heath delights. Some cultivators manage them very successfully in houses with a northern aspect; and in such houses the hardier kinds of ferns may be cultivated with them, and will form a very pleasant accompaniment; but let the house be of what kind it may, above all things it is important that thorough ventilation should be provided; for when the weather is neither frosty nor foggy established plants can scarcely have too much air. The heating apparatus need not be powerful, its only use being to keep the temperature just above freezing point, and occasionally, in wet weather, to dry up damp, at which time the top ventilators should be sufficiently open for the moisture to escape; but where young stock are to be reared, a common garden frame or a low pit is necessary, or at least desirable, as in such places young plants may be made to grow more freely. Indeed, in such places alone thousands of nice little specimens, loaded with flowers, are annually produced for the London market.

Stove and Orchid House.

ORCHIDS.—The general collection may be kept in perfect health now without fire-heat, by shutting up early, and sprinkling the floor of the house to cause a humid atmosphere. Do not shade over-much—generally from ten till three will be quite sufficient from this time, till shading is dispensed with altogether. Small specimens of Stanhopeas should be now shifted into large baskets, in which they can push their flowers downwards. The best material to fill the baskets with is chopped moss, and the tough felt-like fibre of good peat, with all the soil removed. The baskets should be shallow. After shifting, keep them well supplied with atmospheric moisture, but only moderately moist at the root. Specimens that do not require a shift are to be encouraged to grow as soon as they have done flowering, in order to assist the completion of their pseudo-bulbs, and then they must be reduced to a state of rest by gradually withholding water, or to have but little until they again begin to grow. All the Stanhopeas will grow in either house.

Forcing Pit.

MELONS swelling fruit to have plenty of weak manure-water; those ripening their fruit to be kept tolerably dry, but if kept too dry will get infested with red spider, so endeavour to keep them in good health on the smallest possible supplies, and give plenty of air. Those that have borne good crops may be cut back, and set to work again with the help of linings to the beds. Keep these rather close after pruning in, and frequently sprinkle the sides of the frames and the surface of the bed, and give only moderate waterings at the root. Never allow water to fall on the main stems. If the plants cut in appear rather poor, let them break moderately, and then remove a portion of the soil from one side of the roots, and replace with fresh turfy loam. When the roots have run into the new stuff, do the same on the other side, and they will swell a second crop admirably.

PEACHES AND NECTARINES must be fully exposed to the atmosphere as soon as the fruit is gathered. Where the fruit is still hanging, give plenty of air, and every morning a light skiff with the syringe over the leaves. Stop the strongest shoots a few at a time, to swell the ripe buds. Trained trees are generally loaded with superfluous wood, through the prevalence of a delusion in favour of plenty to choose from at the winter pruning. Choose now, and remove all that will not be wanted, and what is left will ripen properly.

VINES now require air night and day from the time the grapes are gathered, unless they are in poor condition, and the wood very green. If so, shut up early, and in another eight or ten days the wood will be getting hard, and then there may be air on night and day. Grapes ripening not to be syringed, but to have a moderately moist atmosphere and plenty of air.

PINES.—The bottom-heat must be kept up, and there must be plenty of room between the plants for a free circulation of air. Do not shade. Maintain a moderate humidity among all advancing crops, and young stock, and in giving air guard against drying winds and draughts by keeping one side close while the other is open. Where the fruit is swelling nicely, sprinkle the surface of the paths and soil frequently; but where the fruit is changing colour, discontinue the sprinkling, and give only just enough moisture to keep the plants in health. After cutting fruit earth up the stools, and give a brisk bottom-heat and plenty of moisture. Beds in which pines are plunged must be kept constantly moist, as the heat will not rise through any dry material.

ON LANDSCAPE GARDENING.

I have been much amused in reading the works of some of our great authors on gardening, especially landscape gardeners; and my opinion is that we have not made much progress in the present century. Tasso and Milton have been considered as the heralds of this improvement. In the garden of Armida of the one, and in the Paradise of the other, some of the beautiful combinations of nature are described; but it really appears to me extravagant to imagine that either of them had an idea that he was giving a design for constructors of gardens to copy; and if not, they only admired what others had admired before them, they only described what others had previously described. Witness Cicero's description of his villa at Arpinum, or that of the villa of Lælius on the height of Misenum. Witness the grounds which Nero laid out, and Tacitus describes. These in some degree anticipated Addison, Pope, Bridgeman, and Kent, whom we consider the originators of landscape gardening in modern Europe, as they not only admired and described picturesque scenery, but they imitated it. There seems to have been almost a spontaneous effort of reformation in the style of gardening in France and England. Dufresnoy succeeded to Le Notre in 1700 as director of the French monarch's gardens. He constructed several gardens in which natural beauties were imitated; but his example was only admired by his countrymen and not followed. Dufresnoy was a man of taste and a poet of merit, and his designs, or similar ones, were executed

before such constructions appeared in England. Addison, in one of his excellent papers on Imagination, in the "Spectator" (No. 414), says English gardens are not so entertaining to the fancy as those in France and Italy, where we see a large extent of ground covered over with an agreeable mixture of garden and forest, which represents everywhere an artificial rudeness much more charming than that neatness and elegance which we meet with in those of our own country. Now Addison in the same essay was advocating landscape gardening, and attempted to exemplify it at his seat, Bitton, near Rugby. He had travelled in France but a few years previously. He was a contemporary of Dufresnoy, and therefore is one of the best authorities. The essay of Addison above cited is dated June, 1712, and is the first that ever appeared in which an imitation of nature is advocated as the basis of ornamental gardening. This was followed by another in the same work (No. 477). To this succeeded an essay by Pope, dated September, 1713, in the "Guardian" (No. 173). Two years afterwards he purchased his villa at Twickenham, and laid out the garden in the style which he admired. In 1732 he published his epistle to Richard Boyle, Earl of Burlington, the first work in which any precise rules for landscape gardening are laid down. The rules, from the shortness of the composition, are of course compendious, but they contain the fundamental principles of the art. Four-and-twenty lines include the whole. I conclude these remarks by quoting them:

To build, to plant, whatever you intend;
To rear the column, or the arch to bend;
To swell the terrace, or to sink the grot:
In all, let nature never be forgot,
But treat the goddess like a modest fair—
Not over-dress, nor leave her wholly bare;
Let not each beauty ev'rywhere be spy'd,
Where half the skill is decently to hide.
He gains all points who pleasingly confounds,
Surprises, varies, and conceals the bounds.
Consult the genius of the place in all:
That tells the waters or to rise or fall,
Or helps th' ambitious hill the heav'ns to scale,
Or scoops in circling theatres the vale;
Calls in the country, catches opening glades,
Joins willing woods, and varies shades from shades;
Now breaks, or now directs th' intending lines;
Paints as you plant, and, as you work, designs.
Still follow sense, of ev'ry art the soul;
Parts answering parts shall slide into a whole.
Spontaneous beauties all around advance.
Start e'en from difficulty, strike from chance.
Nature shall join you, time shall make it grow;
A work to wonder at—perhaps a Stow.

WILLIAM GILES.

Replies to Queries.

Asparagus Bed.—George.—As to the length of time an asparagus bed may be kept on depends very much on soil, climate, and management. We know some beds that are a quarter of a century old and in the finest condition, and we know some that are only seven years old, and that were never worth a farthing per linear yard. Preventing the ripening of seed by early removal of the berries will no doubt tend to conserve the vigour of the plants. Greenhouse plants for winter and spring are plentiful—Cytisus, Primula prænites, Cinerarias, Gauntlet Pelargoniums, White Ageratum, Thysacanthus rutilans, Justicia, Echeveria secunda, Erica hyemalis, and Daphne Indica are the principal subjects grown, but many more may be added to the list. The best plants for plunging in spring are Hyacinths, Tulips, and Crocuses for the first start, and Yellow Alyssum, perennial Iberis, and Arabis alpina to succeed them. If you can do Spirea Japonica well, you will find it one of the very best of plunging plants.

Royal Botanic Society's Last Show.—An error occurred in our report of this show in representing that the awards for Show Pelargoniums in the trade class were to Mr. Turner first, and Mr. Fraser second. The collections from these two exhibitors were considered so equal in merit that to each competitor was awarded a first prize.

Leyton, Walthamstow, Woodford, and Wanstead Floricultural Society.—The flower-show of this society took place at J. G. Barclay's, Esq., Knott's Green, Leyton, on the 11th. Two tickets for the show came into our hands on the 10th, and we had then too many engagements before us to make arrangements for reporting. We will never again report any show unless we have good notice, say a week at least. It is absurd for people who are preparing months beforehand to defer giving us notice till within a few hours of the event, and then expect it to be reported. We have put ourselves to many inconveniences to oblige, but will do so "never no more."

Herbaceous Plants.—J. W. B.—Two of the most beautiful flowers of the present month are Campanula alpina and Phlox amœna. Great sheets of these hardy plants are delightful if well placed, but they have very little beauty in a botanic garden, as they cannot there be associated with suitable relief agents. Let us know when you have obtained all the plants in your list. As to the best time to buy or plant, any time is best that you can do it most conveniently. The rule we follow is this: whenever we meet with a plant of which we desire a bit to begin with, is the best time to secure a bit and make a beginning. In other words, the best time for anything is when you can get it.

Acrophyllum venosum.—Senex.—The judgment was perfectly right. Yours was the largest plant, and was in every sense respectable, but your competitor brought a plant better grown, though a smaller specimen; it was round, dense, and bright, and above every bit of bloom was a red crown of young leaves, which in yours were wanting. We occasionally point out errors in judgment, but we take care to have reason on our side first. According to the canon you lay down, you would place the elephant in the first rank in the order of beauty and the antelope in the last, with the camel between them. When we are called upon to decide that case, if we are told to judge according to beauty, we shall give the antelope first prize, the camel second, and the elephant third.

Weigelia.—H. Watson.—We suppose all the species and varieties now in cultivation to be hardy. We cannot aver that they are so, for we have not tried them all in open borders; some of them, indeed, are scarce and dear, and are not likely to be much planted out until they are cheaper. But we should have no hesitation at all in planting out from pots any and every kind of Weigelia we could get, and this is as good a time as any for such a business.

The Gardener's Magazine.

SATURDAY, JUNE 22, 1867.

ARTIFICIAL STONE is one of the most important aids in the embellishment of gardens. It is true that real stone is to be preferred, but the cost is a serious impediment to its general adoption. The difference of cost of works of art in real and artificial stone is not due alone to the difference in the value of the material, for indeed, bulk for bulk, and regarded as to bulk merely, it is probable that stone would always and everywhere be found cheaper than any imitation of it. The advantage of adopting a composition is that it may be impressed with any desired form without the aid of the sculptor. To cast a mass of pasty material in a mould is a comparatively costless process, but to chisel a block of stone to produce a result equivalent to the taking of a cast of a good pattern must be under any circumstances an expensive proceeding; and the great interest attaching to stone manufacture arises out of the saving of the cost of skilled labour, and the case is analogous to that of printed pictures versus oil or water colour originals. Some fifteen years ago, we strongly recommended to public favour a material which subsequently became famous under the designation of RANSOME'S PATENT IMPERISHABLE SILICEOUS STONE. It was unquestionably the best substitute for stone at that time invented, and was alike remarkable for its hardness and durability, as for its bright crystalline texture, and the highly artistic character of the works—such as balustrades, jardinetts, statuary, fountains, and vases—that were produced in it. This stone was largely employed by architects, builders, and landscape gardeners, as it was soon discovered to be frost-proof, and its beautiful texture and hardness rendered it fit for any purpose to which the best marbles would be applied, provided only it could be modelled or cast in the required form, which was generally speaking a merely mechanical operation.

Very early in the history of the Imperishable Siliceous Stone it became apparent that the process was in some points defective. This stone is wholly composed of siliceous grit and a soda-flux. It is cast in the required forms, and then subjected for a considerable length of time to heat, the effect of which is to partially convert the mass into glass, or rather to form a glassy kind of cement throughout the whole bulk of the material, owing to the chemical combination of the silica and the alkali, in a manner very similar to that which takes place in the manufacture of glass. The necessity of subjecting the material to heat for a great length of time was always felt to be an impediment to its universal employment; for during the process of baking accidents would happen, and at the best there was a great outlay, so that a more simple process of manufacture was greatly to be desired. This has at last been attained, and we were present yesterday at a great demonstration made in the presence of a commission of scientific men at the works of the Patent Concrete Stone Company, East Greenwich, the object of which was to show that imperishable stone of admirable texture and appearance may be made at a cheap rate, and of a quality which renders it in many respects preferable to the best products of the quarry. Mr. Frederick Ransome, the inventor of the new process, was led to its discovery by an inductive process of thought, and it is in some sense a counterpart of his former invention; but the baking process is dispensed with, and there is no need for the employment of pure silica, or for any length of time to elapse between the casting in the mould and the transference of the finished work to the hands of the purchaser. It is an interesting fact that the patent concrete stone is in some part the result of Mr. Ransome's inquiries and experiments when acting as adviser in reference to the preservation of the new Houses of Parliament at Westminster, the facings of which are fast decaying, owing to the corrosive action of the sulphurous acid which always exists in appreciable quantity in an atmosphere charged with the products of the combustion of coal. Mr. Ransome's leading idea has been to take advantage of the readiness with which certain alkalies and silica combine together—in other words, to assimilate the manufacture of stone to that of glass, and to produce in stone, or rather in an imitation stone, all the qualities of glass minus its transparency and fragility, the last named of its properties being doubtless a result simply of the thinness of the plates in which it is manufactured. It is astonishing how simple are the solutions usually to puzzling problems, when we know them; at all events, it proves to be so in the present case.

No. 112, NEW SERIES.—VOL. X:

We saw yesterday some beautiful works of art in imitation stone, produced by a process which we may fairly pronounce to be instantaneous. Certain quantities of chalk and sand are mixed together with a due proportion of silicate of soda. The chemical combination of these ingredients is impossible, and therein lies the secret of success. The soda and the silica separate, and the silica combines with lime and forms a silicate which is of a hard imperishable nature. Thus is produced the patent concrete stone, at a price not greatly in advance of the raw materials of which it consists, and in artistic forms equal in beauty of design and finish to the best productions of the sculptor's chisel—that is, in respect of such works as edging curbs, finials, cornices, and other works of everyday usefulness, and which admit of endless repetition from one design.

The question arose amongst the persons assembled to witness the process yesterday, "How long will this stone last?" We can throw some light upon the question. When Mr. Ransome first discovered the new process, in the year 1863, he placed at our service, for trial at Stoke Newington, several examples of products adapted for garden use. We selected about fifty yards of an elegant edging curb, which was appropriated to form the front of the border in which the principal part of the display by the plunging system is carried out. That edging has been subjected to severe frosts on a cold clay soil, and it is in no way changed, except for the better, since it was originally put down. It is in fact harder than it was originally, and so exceedingly beautiful that we confess we have not yet met with its match in that respect. We cannot doubt, therefore, that the Patent Concrete Stone is destined to play an important part in the embellishment of gardens and buildings, and to serve many other purposes to which stone is usually applied, and at considerably less expense. The company engaged in carrying out Mr. Ransome's patent have judiciously employed able artists to design various useful works in the new material, and we anticipate for it a great and continually increasing demand. At all events, it merits the attention of all whose avocations render the cost of stone a matter of any consideration.

ROYAL BOTANIC SOCIETY.

SECOND GREAT EXHIBITION, WEDNESDAY, JUNE 19.

This exhibition was favoured with delightful weather, and a genial temperature, and the company assembled at an early hour in extra full force. As an exhibition it was quite equal to the average, that is to say, rich, full, tasteful in arrangement, and abounding in interest. Stove and greenhouse plants were largely represented, and formed the principal part of the display, Ixoras, Francisceas, and Pimelias, giving richness of colour, and amply compensating for the scarcity of azaleas and roses. The bank devoted to Pelargoniums was exceedingly rich with the grand groups from Mr. Turner, Mr. Fraser, Mr. Nye, and other exhibitors, and the display of colour here was gorgeous. On the bank immediately facing this were staged the new florists' flowers, of which there were many meritorious contributions. The orchid bank bounding the upper side of the central space was richly furnished, and the groups from the gardens of H. H. Gibbs, Esq., and W. Marshall, Esq., attracted, as they well deserved to do, continuous and unqualified admiration. The smaller banks lower down were filled with groups of fancy pelargoniums, ferns, and miscellanies; and beyond all, shining in the distance like a galaxy of stars upon the horizon, were the lovely flowers of a group of fifty plants of *Lilium auratum* from Mr. Bull, a splendid display of one of the most valuable acquisitions of modern times. That there should be a ridiculous group of the ridiculous *Raphanus caudatus*, or tailed radish, beside the *Lilium* was a misfortune; but probably the radish is not so ridiculous a thing considered commercially as horticulturally. Beyond, in the annex, fruits and flowers abounded, and as usual very few people could see them: it is an inconvenient narrow corridor, and sometimes a trap for the east wind. Farther on still, the tent of Mr. John Waterer, of Bagshot, glowed with the splendour of thousands of rhododendrons, azaleas, and kalmias, not wanting in admirers, for the tent was crowded from soon after two o'clock till dusk. It may be gathered from the foregoing, that people of all sorts had seasonable entertainment, and that this was in every sense a glorious exhibition, and a reunion alike for horticulturists and the seekers of pleasure. Let us now proceed to report in the usual way on the composition of the gathering in general and in particular.

PELARGONIUMS constituted the principal feature as respects a display of colour, and were extremely good. In the trade class for nine show varieties, Mr. C. Turner, of Slough, first, with fine fresh specimens of Royal Albert, Viola, Miss Burdett Coutts, Patroness, Lord Clyde, Guillaume Severeys, a splendid plant of this splendid variety; Regina forma-a, Jewess, Mary Hoyle, very fine, the petals as broad, and the flowers as round and smooth as when exhibited as a seedling. How well Mr. Hoyle's varieties wear! Mr. Fraser, of Lea Bridge Nurseries, second, with Amy, Fair Rosamond, Excelsior, Favourite, Lord Clyde, Princess of Prussia, one of the finest whites known; Inez, Ariel, Guillaume Severeys, the last extra fine. Messrs. Dobson and Son, of Isleworth, third, with Pasha,

Purity, Patrician, fine, the flowers large, smooth, and richly coloured; Léopard, Caractacus, splendid for colour; Constance, Regina formosa, Favourite, Bacchus.—In the class for nine plants from amateurs, Mr. Nye, gardener to J. B. Foster, Esq., Clewer Manor, Windsor, first, with Madlle. Patti, Conflagration, Pericles, Empress Eugénie, Lord Chancellor, International, Perdita, Lord Clyde, Fair Rosamond. Second, Mr. J. Ward, gardener to F. G. Wilkins, Esq., Leyton, with Diana, Viola, Bacchus, Empress Eugénie, Conflagration, Madame Furtado, Caliban, Fairst of the Fair, Lord Clyde. Third, Mr. Crawley, gardener to C. J. Houghton, Esq., Leyton: in this lot were nice examples of Landseer, The Charmer, Lucy, Mirabeau, and Rosy Gem. The tickets attached to Mr. Crawley's plants were very badly written; we hope he will be enabled to improve this part of his contribution in any future appearance as an exhibitor. Fourth, Mr. Windsor, gardener to R. Ravenhill, Esq., Essex, who had good examples of Pericles, Eugénie Lagraverre, a good white; Sir Colin Campbell, Caractacus, a small flower, wanting finish, but glorious for its lovely tinge of violet and its abundance of bloom; Conqueror, and Madlle. Patti.—In the trade class for six fancies, Mr. Fraser, of Lea Bridge Road, first, with the finest six Pelargoniums (of any class) in the show; they were of great size, most beautifully moulded to a watch-glass convexity, extravagantly flowery and fresh; in fact, verging towards the azalea extreme of colour and precise training; shall we say?—yes, we will say—the perfection of perfectness in every respect except one—they were too much alike; they wanted at least two very light kinds to make variety of colouring. The varieties in this group were Hebe, Ellen Beck, Miss in her Teens, Lady Craven, Arabella Goddard, Roi des Fantaisies. Second, Mr. C. Turner, with Sarah Turner, Delicium (passé), Anne Page, this turns out to be a first-rate exhibition variety, and justifies the place given it the other day as a seedling; Silver Mantle, Mrs. Dorling, Clemantbe, the last extra good. Third, Messrs. Dobson and Son, with very pretty, small, round-headed plants of Fairy, Arabella Goddard, Lucy, The Rover, Delicium, Acme, Roi des Fantaisies.—In the class for amateurs, first, Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, with pretty round-headed plants, in an admirably managed and quite fresh state, of Ellen Beck, Hebe, Marionette, Cloth-of-Silver, Celestial, Roi des Fantaisies. Second, Mr. Bailey, gardener to T. T. Drake, Esq., Amersham, Bucks, with Clemantbe, Delicium, Zoe, Eleanor, Madame Dolby, Bridesmaid. Equal second, Mr. Windsor, with Miss in her Teens, Delicium, Mrs. Ford, good, and especially so for lively colour; Roi des Fantaisies, Arabella Goddard, Godfrey Turner. Third, Mr. S. Crawley, gardener to E. J. Houghton, Esq., Leyton, with Loveliness, Cloth-of-Silver, Arabella Goddard, Delight, Countess of Waldegrave, Mrs. Ford. This lot was so well done that we can consistently encourage Mr. Crawley to persevere; in a few years he may rise to the top of the tree, and when he is there we hope he will write plain legible tickets, as he will be farther off than now.

ORCHIDS.—In the great class for fifteen plants, Mr. C. Penny, gardener to H. H. Gibbs, Esq., of St. Dunstan's, Regent's Park, took first place most honourably with a splendid group, comprising a fine example of *Cypripedium grandiflorum*, with twenty flowers; *Cattleya mossiæ*, *Cattleya mossiæ superba*, *Cypripedium barbatum superbum*, extra fine; *Aerides crispum Lindleyana*, *Saccolabium guttatum*, *Anguloa Ruckeri*, *Oncidium crispum*, *Odontoglossum nævium major*, with eight spikes out and five coming, fine; *Vanda suavis*, *Cœlogyne pandurata*, *Odontoglossum cordatum*, with two spikes; *Dendrobium Dayanum*, with six spikes; *Aerides Larpentea*, *Lælia purpurata*. Second, Mr. Wilson, gardener to W. Marshall, Esq., Enfield, with a beautiful group, comprising a fine *Cypripedium Stonei*, with three flowers; *Cypripedium villosum*, admirably done, with eighteen fine flowers; the pretty *Orchis foliosa*, which lights up the grassy hollows of Madeira with its lovely spikes of purple; *Aerides odoratum*, *Dendrobium Dalhousianum*, very fine; *Dendrobium formosum giganteum*, *Cattleya mossiæ*, *Epidendrum vitellinum*, dirty and out of season; *Phalenopsis grandiflora*, *Cattleya Warneri*, with two flowers; *Odontoglossum hastatum*, *Selinipedium caudatum*, with tails over two feet long; *Lælia purpurata*, and *Calanthe veratrifolia*. Third, Mr. Gidney, gardener to Rev. W. Ellis, Hoddesdon, with good examples of *Aerides Lobbiana*, two spikes of rich purplish rose flowers; *Aerides Larpentea*, *Cattleya Aclandæ*, and others. Fourth, Mr. Wiggins, gardener to W. Beck, Esq., Isleworth, with *Saccolabium præmorsum*, *Cypripedium Hookeri*, with seven flowers, a beautifully finished example; *Oncidium papilio*, with three of its peculiar butterfly-like flowers and leaves finely spotted; *Lælia purpurata*. Mr. Peed had a pretty group, in which we noticed a nice *Dendrobium densiflorum* and a good *Aerides odoratum*.—In the trade class for six, Messrs. Veitch and Son had first place, with *Cypripedium Veitchii*, in the way of *C. grandiflorum*; *Anguloa Clowesii*, *Aerides Lindleyana*, *Cypripedium barbatum major*, *Saccolabium guttatum*, *Lælia purpurata*. Second, Mr. B. S. Williams, with a fine *Cypripedium barbatum superbum*, *Phalenopsis grandiflora*, *Aerides odoratum purpureum*, *Dendrobium moschatum*, a fine example of this beautiful Dendrohe, which is always worth notice for its curious mixture of amber, brown, and pink colours; *Vanda suavis*, *Saccolabium guttatum superbum*. Third, Messrs. Jackson and Son, of Kingston, who had a pretty *Aerides Lobbiana* and a good *Lælia purpurata*, with others.

(To be concluded next week.)

FINAL GATHERINGS FROM THE MANCHESTER NATIONAL EXHIBITION.

As an inhabitant of the district, and as one deeply interested as an exhibitor in the success of this great undertaking, I beg you to accept the hearty thanks of myself and friends for your full, impartial, and most instructive report published in last week's Magazine. That you did not spare us when speaking of our failings is consistent with the plan on which the Magazine has always been conducted, and the only plan that should be tolerated; for what good use, I would ask, can be accomplished by reports that consist mainly of flatteries, ill or well bestowed, and which therefore do not furnish to faulty exhibitors a single hint of what is really required of them? Having made copious notes on the various subjects exhibited, I will, with your permission, make a supplementary report, taking up only those subjects on which you have not made any remark.

MR. JOSEPH NEWTON'S LANDSCAPE PLANS.—These were exhibited by Mr. Joseph Newton, the well-known landscape gardener and garden architect, of 74, Oxford Terrace, Edgeware Road, London, and were attractive on account of their great size and exceeding beauty. I was particularly

attracted by Mr. Newton's plans for Sefton Park, Liverpool, which I consider far preferable to those from Mr. Hornblower, the favoured competitor, because the main idea is a park—that is to say, the designs have what is termed "breadth," and are calculated to produce spacious and dignified landscape effects; whereas Mr. Hornblower's are broken up into a number of separate gardens, into so many separate blocks and partitions in fact, that "breadth" is lost entirely, and there is no chance for the eye to range over an ample space, and enjoy the sense of liberty which belongs to a scene the boundaries of which are nowhere clearly defined. But passing from this topic, which is in a measure controversial, let me speak of Mr. Newton's plans as spirited, original, grand in purpose, and, in respect of mechanical getting up, perfect. I was much pleased with a plan for a great hotel with still greater conservatory, the whole being intended as a sanatorium for invalids, who would walk from their chambers into a winter garden, richly furnished with trees, flowers, and birds, without once breathing the chilly atmosphere outside—a capital subject this for some of those speculative spirits who love the Limited Liability Act, and are ever on the look-out for occasions to start companies. Probably an invalid's winter residence would be a better idea for a speculation than a railway to go nowhere, or the self-acting salt-box working by a chronometer movement. Mr. Newton also exhibited plans of works he has accomplished in various parts of the country. His style appears to be English in its essentials, but enriched with Italian features in parts where high keeping and finish are desired.

MR. CARR'S BEEHIVES.—These were placed on the summit of the mound whence a view of the largest tent was obtained, and they were exhibited by Mr. Carr, of Claydon Bridge, Newton Heath. In one square box-hive with glass sides a colony of Ligurian bees presented a very attractive appearance, being in full work, and the combs as regularly constructed as the bars from which they were suspended. I did not ask Mr. Carr whether guide combs had been employed to produce this regularity; but I found much to interest me in Mr. Carr's little lecture, delivered every three minutes, and still more in the ridiculous questions asked him by people who by their appearance and manner one would credit with at least a superficial knowledge of the history of the honey-bee. By patiently listening to what took place during a quarter of an hour, I learnt that the people generally (on the first days of the show, when the upper ten were present) are ignorant of the relations of the queen to the community, and of the fact that only one queen can reign at a time; that they know nothing of the sexual peculiarities of the three divisions of the community, or of the transformations through which every bee passes in common with all other insects, or of the manner in which honey and bread are collected, or of the respective uses of these two aliments in the economy of the hive. Our Editor is an old bee-keeper, and an ardent investigator in this department of natural history. He gives the public the benefit of his researches occasionally in some expensive work, such as the "Intellectual Observer," but not a word on the subject does he ever favour us with in the pages of the Magazine. If he does not cut this out of my copy, I shall hope to see something come of it. Mr. Carr had a pretty Unicomb Hive—that is to say, a glass hive admitting only one comb, and this exposed to view in every part and on both sides, so that it is an easy matter at any time to find the queen and observe her movements. In this unicomb the bees were Ligurians, or black bees, which Mr. Carr avers to be far superior to our old friends the brown bees in working power, fecundity, and homeliness. By the last term I understand that when swarming they never go far away from their owner's apiary.

FERNS.—Mr. Shaw had the courage to show a fine plant of *Trichomanes radicans*, the Killarney filmy fern, without a bell-glass. It must have been well prepared for the trial, for it stood it well, and on the last day of the show it was looking nearly as fresh as on the first. Mrs. Hampson showed *Adiantum pedatum* nicely done; this is a fern best of all adapted for exhibition by amateurs who cannot keep costly collections, as it has the grace and character of a Maidenhair, and grows most luxuriantly with shade, shelter, and moisture, and in winter will bear ten degrees of frost without harm. Mr. B. S. Williams brought a new *Gleichenia*, which I should like to know more about, for it appears to have a habit well calculated for specimen cultivation. Messrs. Veitch had in their trophy a fern called *Athyrium goringianum pictum*. I have no doubt this is an *Athyrium*, but it has much the appearance of *Pteris tricolor*, and I think will be far preferable to that generally disappointing fern; for it not only has some nice shades of purplish rose and silvery gray, but these are harmonised with a blackish tinge of just the kind that in tricolor-leaved geraniums add so much to the effect of the other colours.

THE JUDGING.—Whatever individual exhibitors might sometimes have felt—and we know that the only way to satisfy some men is to give them first prizes, whether they deserve them or not—there can be no question that the judging was a masterly performance. I, in common with other exhibitors, left the show about noon, and by about one we were allowed to enter again, for the judging was finished. Very different this to the slow and hesitating work we have long been accustomed to, seeing the judges potter about for hours after the admission of visitors, and not give satisfaction to any one after all. I suppose the actual work of judging did not occupy three quarters of an hour, and this the second greatest and grandest exhibition of modern times. But we need not wonder, for the best men from all parts were selected for the work; even Mr. Warner came up to join with Mr. Anderson and other great authorities in judging the orchids; Mr. Moore, of the *Gardener's Chronicle*, was a judge in one department, and Mr. Hibberd, of the *Gardener's Magazine*, in another; and to such names may be added those of Mr. Mitchell, head gardener to the Duke of Hamilton, at Hamilton Palace; Mr. Bullen, the once famous orchid grower, of Leicester; Mr. McKenzie, of Alexandra Park; Mr. Richards, of Grimston Park, Tadcaster, and so on, and so on; men whose characters are as good guarantees as their knowledge, and whose much experience fits them for quick and just decisions in great undertakings. And I shall add, as an exhibitor, that Mr. Findlay was equally just and considerate; he not only gave us no cause to complain, but every reason to thank him for his readiness to oblige, and his anxiety at all times to consult our interests. I am sorry that some exhibitors took away their plants before the show was over; it was too bad; but never mind, the entire thing was a success, and we have every reason to rejoice. I trust I have been impartial in making these few notes; I have at least endeavoured to be so, and by my eurd (which I enclose) you will see that I have not referred in any way to anything I exhibited, or to anything in which I have the least possible interest. What I say is, as it professes to be, *pro bono publico*.

AN EXHIBITOR.

NATIONAL TULIP SHOW.

The annual moveable exhibition of tulips, grown by florists from all parts of England, was held at the Mechanics' Institution, Stockport, under the superintendence of the South Lancashire Tulip Society, from the Red Lion, Heaton Lane, their operations having been protected by a guarantee fund sufficiently large to give the greatest encouragement to exhibitors. The arrangements were entrusted to Mr. Woolley and Mr. Wm. Longson; and the result, both financially and experimentally, has been perfectly satisfactory, and is highly creditable to the locality. The entries, which were 52 in number, included growers from Birmingham, Gloucester, Whitley, Leeds, Sheffield, Derby, Warrington, Stockport, and other parts of Lancashire; and the prizes offered varied from £4 to 1s., divided into eleven sections. The blooms, about 2,000 in number, were classed in the lecture-hall by eleven o'clock, when the judges proceeded to make their awards of the successful exhibitors in the various classes. The disinterestedness of the awards may be assured from the fact that the gentlemen engaged for that delicate and difficult service came from various localities, and were conspicuous for their extensive knowledge of the recognised standards required to constitute prize tulips. They concluded their labours a little before three o'clock; and their decisions, we believe, are admitted on all hands to be sound and tenable in floral law. The successful exhibitors, with the names of the winning flowers, are as follows:—

First Pan of Twelve, Mr. Wm. Lea: Mrs. Lea, Heroine, Violet Amiable, Mrs. Pickerill, Curion, Masterpiece, Sans Joe, Ajax, Duchess of Sutherland, Bacchus, Sarah Hedley, Triomphe Royal.—Second Pan of Twelve, Mr. John Turner: Apelles, Charles, Mrs. Pickerill, Violet Amiable, Heroine, Mrs. Lea, Sans Joe, Polyphemus, Alex. Magnus, Denman, Aglaia, Triomphe Royal.—Third Pan of Twelve, Mr. Wm. Longson: Waterloo, Lord Lilford, Violet Amiable, George Glenny, Heroine, Lady Crew, Sans Joe, Paxton, Denman, Queen Charlotte, Aglaia, Lavandicken.—Fourth Pan of Twelve, Mr. George Mort: Colbert, John Wilkinson, Seedling, Amiable, Compte, Heroine, Captain White, Slater's Telemachus, Charlotte, Denman, Aglaia, Bion.

First Pan of Six, Mr. Wm. Lea: Masterpiece, Violet Amiable, Heroine, Ajax, Bacchus, Triomphe Royal.—Second Pan of Six, Mr. Peter Swindells: Charles, Beauty, Andromeda, Sans Joe, Denman, Aglaia.—Third Pan of Six, Mr. John Turner: Charles, Adonis, Heroine, Sans Joe, Denman, Aglaia.—Fourth Pan of Six, Mr. H. Travis: Charles, Violet Amiable, Heroine, Sans Joe, Atlas, Aglaia.—Fifth Pan of Six, Dr. Hardy: Garibaldi, Queen of North, Heroine, Sir J. Paxton, Lord Denman, Lady C. Gordon.—Sixth Pan of Six, Mr. Sharpe: Masterpiece, Violet Amiable, Heroine, Storer's Seedling, Duchess of Sutherland, Aglaia.

First Pan of Three Feathered, Mr. Wm. Lea: Heroine, Paxton, Violet Amiable.—Second Pan of Three Feathered, Mr. Haynes: Lord Sydney, Seedling, Heroine.—Third Pan of Three Feathered, Mr. John Morris: Devonshire, Bienfait, Aglaia.—Fourth Pan of Three Feathered, Mr. Millar: Masterpiece, Heroine, Edgar.—Fifth Stand of Three Feathered, Mr. Haynes: Royal Sovereign, Seedling, Aglaia.—Sixth Stand of Three Feathered, Mr. Parkinson: Willison's King, Victoria Regina, Heroine.

First Stand of Three Flamed, Mr. Haynes: Paxton, Denman, Triomphe Royal.—Second Stand of Three Flamed, Mr. T. Mellor: Masterpiece, Bacchus, Aglaia.—Third Stand of Three Flamed, Mr. J. Moores: Polly, Denman, Aglaia.—Fourth Stand of Three Flamed, Mr. Haynes: Triomphe Royal, Duchess of Sutherland, Lord Sydney.—Fifth Stand of Three Flamed, Mr. Thurston: Sir J. Paxton, Lord Denman, Aglaia.—Sixth Stand of Three Flamed, Mr. Wm. Lea: Sans Joe, Duchess of Sutherland, Aglaia.

First Stand of Two, Feathered and Flamed, Mr. T. Mellor: Charles, Sans Joe.—Second Stand of Two, do., Mr. J. Moores: Heroine, Denman.—Third Stand of Two, do., Mr. Wm. Lea: Heroine, Devonshire.—Fourth Stand of Two, do., Mr. Wm. Longson: Heroine, Denman.—Fifth Stand of Two, do., Mr. W. Davenport: Charles, Polyphemus.

The Best Feathered Tulip in the whole Exhibition, Mr. John Turner: Apelles.

The Best Flamed, do., Mr. H. Travis: Atlas.

FEATHERED BIZARRES.—1, Apelles, John Turner; 2, Charles, Thomas Mellor; 3, Paxton, Wm. Lea; 4, Devonshire, Wm. Lea; 5, Magnus, John Hart; 6, Lord Lilford, Luke Ashmole; 7, Robert Guest, John Morris; 8, Masterpiece, T. Mellor; 9, Surpass Catalaque, John Knott; 10, Lord Byron, R. Keyzey.

FEATHERED BYBLEMENS.—1, Adonis, Wm. Lea; 2, Lancashire Hero, G. Mort; 3, Seedling, G. Mort; 4, Queen of North, Wm. Lea; 5, Violet Amiable, Wm. Lea; 6, Cotterill's Purity, Wm. Lea; 7, Seedling, David Jackson; 8, Bessie, Wm. Lea; 9, British Queen, W. Willison; 10, Seedling, — Haynes.

FEATHERED ROSES.—1, Heroine, R. Keyzey; 2, Aglaia, Wm. Lea; 3, Kate Connor, Dr. Hardy; 4, Beauty of Home, G. Mort; 5, Julia Farnese, R. Keyzey; 6, Lady Crew, John Knott; 7, Cerise primo Superb, J. P. Sharp; 8, Inimitable, J. Hart; 9, Madame St. Arnaud, J. Morris; 10, Andromeda, John Knott.

FLAMED BIZARRES.—1, Paxton, John Hart; 2, Sans Joe, T. Mellor; 3, Merit, Wm. Hart; 4, Polyphemus, J. Thurston; 5, Mr. Hextall, — Haynes; 6, Emperor Nicholas, Dr. Hardy; 7, Dr. Hardy, — Haynes; 8, Paxton, J. Thurston; 9, Saxton, W. Hart; 10, Lord Palmerston, — Haynes.

FLAMED BYBLEMENS.—1, Lord Denman, W. Davenport; 2, Surpassant, J. Hart; 3, Princess Royal, D. Woolley; 4, Alexander Magnus, Hugh Housley; 5, Gavazzi, J. Hart; 6, Duchess of Sutherland, Dr. Hardy; 7, Wallers, G. Mort; 8, Bienfait, W. Davenport; 9, Salvator Rosa, Joshua Hague; 10, Queen of North, H. Steward.

FLAMED ROSES.—1, Triomphe Royal, Wm. Hart; 2, Aglaia, J. Thurston; 3, Mabel, T. Mellor; 4, Juliet, W. Willison; 5, Lavandicken, W. Davenport; 6, Rose Guerre, G. Mort; 7, Camillas, G. Mort; 8, Madame St. Arnaud, T. Mellor; 9, Village Maid, G. Mort; 10, Lady C. Gordon, J. Thurston.

BREEDERS.—First Stand of Six, Wm. Longson: Dr. Hardy, Sarah, Annie Hathaway, Paxton, Sutherland, Mabel.—Second Stand of Six, Wm. Lea: Nicholas, Adonis, Olivia, Seedling, Miss Atherton, Queen of England.—Third Stand of Six, G. Mort: Unknown, Lady Atherton, Queen of England, Paxton, Seedling, Juliet.—Fourth Stand of Six, T. Mellor: Storer's Seedling, Duke of Manchester, Annie McGregor, Sir Colin Campbell, Sarah Sophia, Queen of England.

BREEDERS.—First Stand of Three, Wm. Lea: Ariosta, Miss Atherton, Queen of England.—Second Stand of Three, J. Moores: Paxton, Earl Warwick, Seedling.—Third Stand of Three, Jno. Warren: Paxton, Seed-

ling, Seedling.—Fourth Stand of Three, Wm. Longson: Paxton, Adonis, Miss Boot.—Fifth Stand of Three, T. Mellor: Storer's Seedling, Wm. Bentley, Queen of England.—Sixth Stand of Three, P. Swindolls: Duke of Ifamilton, Unknown, Unknown.

BIZARRE BREEDERS.—1, Seedling, Wm. Lea; 2, Nicholas, W. Longson; 3, Paxton, J. Hall; 4, Seedling, W. Lea; 5, Ashmole No. 1, Luke Ashmole; 6, Seedling, W. Lea.

BYBLEMEN BREEDERS.—1, Adonis, J. Hart; 2, Delicata, J. Moores; 3, Miss Whitaker, G. Mort; 4, Duchess of Sutherland, W. Longson; 5, Seedling, J. Thurston; 6, Miss Forrest, J. Peacock.

ROSE BREEDERS.—1, Queen of England, Wm. Lea; 2, Juliet, Wm. Lea; 3, Martin's Seedling, John Hart; 4, John Waterson, T. Mellor; 5, Mabel, Wm. Longson; 6, Veritas, R. Keyzey.

The Best Breeder in the whole Exhibition, T. Mellor: Storer's Seedling. Dr. Hardy, of Warrington, no mean authority on the subject of tulips, pronounced the show, as a whole, to be the best exhibition of the kind he had ever seen. The winner of the highest premium—twelve dissimilar tulips in section 1—was Mr. Wm. Lea, of Leigh, Lancashire, who also carried away seventeen other prizes, a most successful exhibitor in this part of the country. The best flower in that pan, raised by himself, was named "Mrs. Lea," as a compliment to his mother, and was a remarkably fine bloom, as were the feathered specimens, "Masterpiece," "Triomphe Royal," and the flamed "Bacchus." The second and third pans, in the same section, were highly creditable to the growers, Mr. John Turner and Mr. Wm. Longson, and were also greatly admired by the visitors, who were admitted from three to six o'clock, on the payment of 1s. each towards the general fund. It is worthy of remark that, notwithstanding that this was an assemblage of the first tulip growers in England, the best feathered flower in the whole exhibition was cultivated in the northern provinces, by Mr. John Turner, of Stockport; the best flamed came from Mr. Travis's garden, Royton; and the best breeder was shown by Mr. T. Mellor, of Staleybridge. The sum expended in prizes will be about £50. The sight of 2,000 tulips, with their bright or delicate tints, was very pretty and pleasing to the senses, but the effect was increased by the display of a number of herbaceous and greenhouse plants in flower, from the Vernon Park Conservatory, including some splendid caladiums, fuchsias, geraniums, and balsams, relieved by tastefully-arranged bouquets and baskets of cut flowers. The exhibition, which terminated at six o'clock, has been a decided success; and, we believe, wherever the "National" may be held next year, our southern growers will have some difficulty, whether for purity, or clean bloom, in beating the flowers cultivated in the northern provinces of England. The lovers of tulips are much indebted to the honorary secretaries and the committee for their efforts to make the National Tulip Show a successful exhibition.

Besides the well-known old varieties, which were mostly shown in fine style, the seedlings of Messrs. Haynes, Mort, and Jackson were very promising. Dr. Hardy's Ajax was very fine, both in the first stand of twelve and the first stand of six. Storer's Dr. Hardy is a splendid flamed bizarre of the red class, but unsurpassed in the richness of its colours.

It will gratify all lovers of the tulip to know that the show was a success financially. After paying all the prizes and expenses, there is a small balance to hand over to the Stockport Mechanics' Institution. B.

CHICHESTER HORTICULTURAL SOCIETY.

The summer exhibition in connexion with this society took place in the gardens attached to the Episcopal Palace, on the 13th inst. The weather was unpropitious, but the attendance proved to be better than could have reasonably been expected, and the beautiful grounds presented a very lively appearance in the afternoon. The plants were decidedly more numerous and better grown than in former years. In vegetables and fruit there was not much competition, and nothing worthy of note. The bridal bouquets exhibited by Messrs. A. Scott and Son, North Gate Nursery, were designed with exquisite taste. Mr. J. M'Ronald, West Gate Nursery, sent a well-selected score of varieties of the British ferns, some specimens of the new radish (*Raphanus caudatus*), and a few seedling gloxineas delicately margined. From Mr. S. Evans, of North Street, came a seedling *Tropaeolum*, which for its free flowering properties promises to extinguish the Ball of Fire. He had also some very good seedling scarlet geraniums. The orchids were numerous and well grown: they were sent by Mr. Cameron, gardener to his Grace the Duke of Richmond; Mr. Young, gardener to W. H. Stone, Esq., M.P., of Leigh Park; Mr. Carter, gardener to Mr. Kent, of Goodwood; Mr. Dover, gardener to H. Clarke, Esq., Fareham; and Mr. Wilson, gardener to J. E. Fletcher, Esq., of Dale Park. The latter sent a *Saccolabium guttatum*, with four fine spikes fully expanded; Mr. Cameron had a splendid variety of *Cattleya*. Foliage plants were represented by plants which have more than once carried off metropolitan prizes: there was, for instance, that marvellous plant of *Stangeria paradoxa*, which nobody has been able to grow so well as Mr. Young, and which has this season produced a cone more than a foot long. The geraniums, though numerous exhibited, were by no means fine. Of stove and greenhouse plants there was a good display; *Clerodendron Balfourii* and a well-flowered *Bougainvillea glabra* were the most noteworthy plants. Some very good fuchsias were shown by Mr. Vickery, gardener to J. C. Couper, Esq., of Felpham. The Achimeres, Balsams, Gloxineas, and Calceolarias were better than last year. On the whole, this was a show such as can seldom be seen in so small a town.

NATIONAL SCHOOL FLOWER-SHOW AT HAMPSTEAD.

The annual summer show of wild flowers, window plants, &c., took place on Wednesday, the 12th, at the Infant Schoolroom, Bradley's Buildings, Hampstead. By the rules anyone was allowed to exhibit, but only children of the Parochial or West-End Day or Sunday Schools were permitted to receive prizes, and, consequently, they were the principal exhibitors. Though not so extensive as last year, owing to Whitsuntide coming later, and also to the changeable weather, the show was a very satisfactory and creditable one, the tasty arrangement of many of the specimens evincing much patient labour on the part of the youthful exhibitors, who, in some instances, were assisted by their parents. One boy, exhibiting in Division C, had formed, with the assistance of his father, a representation of a somewhat monstrous donkey (in dried laurel leaves), bearing a very portly man, whose scarlet jacket was made of geranium leaves, the whole being surrounded by a very pretty leaf-border. This design, though we know

not for what reason, was said to be emblematical of Reform, and gained, as it well deserved, a second prize for its exhibitor, George Payno. Perhaps the most commendable of all the specimens was one shown in Division B, consisting of a cottage—appropriately named “Wood Cottage”—built, in a neat and proportionate style, with something like eighty different kinds of wood, each being correctly named, by Frederick Palmer, to whom a first prize was awarded, viz., a box of geological specimens, accompanied by a catalogue of the objects, written by Mrs. Frederick Hill, the donor of this and other prizes. From two to five o'clock, the charge for admission was sixpence, and a sum of £2 13s. was taken at the door. From seven to nine o'clock, the charge was twopence, and £1 7s. 2d. was taken. The children of the Parochial and West-End Schools were admitted, without payment, from half-past five to half-past six o'clock. The prizes were distributed by the Rev. C. M. Harvey, M.A., and the Rev. G. A. Herklots, M.A., the incumbent being unable to attend. A large number of the prizes were kindly given by Mrs. F. Hill and the Rev. C. M. Harvey, the remainder being purchased out of the proceeds of the exhibition; they consisted of work-boxes, writing-cases, money-boxes, vases, and other elegant and useful articles.

During the day the proceedings were enlivened by the performances of the School Band, under the direction of Mr. Loader, and we embrace this opportunity of informing our readers that a sum of £15 would be a great service to the band, as the youths composing it require new uniforms, and there are no funds with which to provide them. Some subscriptions for this purpose have already been received, and any further amounts would be gladly accepted by the Revs. C. M. Harvey, G. A. Herklots, or Mr. Loader.—From the *Hampstead Local Paper*.

PLANTS FOR ROOM DECORATION.

We will commence with *Aralia Sieboldii*, a native of Japan. This is a plant of great value for several reasons. It is nearly, if not perfectly, hardy. It is the finest of all plants for growing indoors at all seasons, and it is one of the best things that can possibly be used in what is called the sub-tropical garden. We have seen it during the present winter in sitting-rooms make fresh green leaves such as no other plant we know of would make in a like position, and it stands the drying air of the drawing-room with perfect impunity at all times. Large, bold, and handsome in leaf at the same time, it is therefore highly to be recommended to all who cultivate plants in the house. For that purpose it is better purchased in a comparatively young, or at all events simple-stemmed state, as in such conditions most “foliage plants” look better than when branched. If had in a fresh state, and with plenty of room for the roots in the pot, it will require no attention beyond watering for a long time. Dust may settle on it, to be sure; but being a large and smooth-leaved subject, that may be removed in a few moments with a moist sponge. For the flower-garden it is fine for grouping with the other plants lately recommended for such, and, when plentiful enough, may be tried out all the winter. We have lately seen plants of it that have stood out all the past very severe and nasty winter, and that had made fine fresh green shoots before the end of May. Till plentiful enough, it had better be protected in winter in a cold pit or greenhouse. It is also one of those things that may be utilized for the conservatory in winter and the flower-garden in summer; and if it prove as hardy as we believe it to be, it must become one of the most popular plants in the country. There are two or three variegated varieties.

It is very likely that other plants closely allied to this are equally good for room decoration, and we have had recently a great number of its relatives of handsome habit, introduced from a very high altitude in South America; but we had better confine ourselves to such things as have been proved to be good. The foregoing is not at all known in England for the purpose named; but the Indiarubber plant (*Ficus elastica*) has been used a good deal with us—not, however, so much as it deserves to be. When in a young and simple-stemmed condition, there is nothing to surpass it for doing well in a living room. We have seen it flourish greenly for years in a house, without either potting or any other attention beyond watering. Its leaves are so large and smooth that when they become dusty they may be cleaned in a few moments with a moist sponge. It, too, should be first placed in the house when in a comparatively dwarf state, and always with a simple or unbranched stem. When once it breaks into several stems and becomes tall and branched, it is no longer so handsome, and should be cut down and propagated, or exchanged for dwarf young plants. But if we begin with a strong dwarf plant, say at about a foot or fifteen inches high, it will be a long time before it grows out of its very comely habit. When first placed in the house, it should have what gardeners call plenty of pot-room, so that it may require no fresh “shift” for a couple of years. When it does require potting, it should be given a few weeks in the hothouse afterwards, so that it may become firmly rooted in the new soil; at least, this is the best plan, though it may be by no means necessary. So much for the Indiarubber plant. Doubtless there are others of this genus which would do equally well in the house, but it is the best we know of at present.

There are no plants more suited for this purpose than the best of the dwarf palms, but they are as yet so scarce in England that we feel it would be little more than a waste of space to describe them. Seen, however, we hope to find them grown freely by our nurserymen. In Paris they are grown in many houses; but the French are far before us as regards the culture of handsome and graceful plants for the house. A nurseryman who lives at Versailles lately told us that he annually sells in the Paris market 5,000 plants of one species for this purpose alone, and that by no means a cheap plant—*Dracena terminalis*. The myrtle in its various forms is one of the best plants for house culture. It should be grown in a dwarf, neat condition, and not allowed to grow up tall and straggling, as is usually the case. Instead of disliking the dry air of a house, the myrtle seems to enjoy it. The finest flowering plant for the house is *Vallota purpurea*—or the Scarborough Lily, as it is sometimes called. It seems to enjoy the window almost as much as the myrtle, and is a fine showy thing when in flower. Among the most graceful of all for our purpose are some of the dwarf green kinds of *Dracena*. We should scarcely advise the introduction of the crimson-leaved kinds, except to those who can afford to run the risk of losing them. Of course they may be introduced for a short time with impunity. Many of the *Yuccas* enjoy the air of a house very well, and as some, like *Stokesii*, are very prettily marked, they will be found very desirable. Not having mentioned half the plants which we know to be useful in this way, we shall continue the subject at a future day, and add a few remarks as to their culture and treatment.—*The Field*.

THE MOST BEAUTIFUL WILD FLOWERS: WHERE TO GATHER AND HOW TO CULTIVATE THEM.

Now we come to the Heath family, and that it is likely to afford beauty and interest I need hardly remind any person who has seen the wide spread of beauty on our heaths and mountains in summer or autumn. But of the variety of loveliness to be had from even our national heaths few people have any idea; not even the sportsman or botanist who continually wanders over their fragrant wilds, or the plant collector, with a quick eye for everything beautiful or noble in the way of a plant. The species themselves are of course very beautiful; but from time to time sports have appeared amongst them which nurserymen have preserved; and thus, where you see a good collection of these, the variety of charming colour is quite amazing. Though I knew all the species and admired them, I had no idea of the beauty of colour afforded by the *varieties* till I visited the Comely Bank Nurseries at Edinburgh a couple of years ago, and there found a large piece of ground covered with their exquisite tints, and looking a most refined flower garden. But if all this beauty did not exist, the charms of the usual forms of the species, as spread out on our sunny heaths, should suffice to warrant their culture on the rockwork or among dwarf shrubs; and nearly allied to them we have the interesting bog *Vacciniums*, which may be cultivated in marshy or peaty ground. To these belong the cranberry, bilberry, and whortleberry; and for some of these and the American kind people have ere now made artificial bogs in their gardens. The little creeping evergreen *Arbutus uva-ursi*, or bearberry, is very neat in the garden or on rockwork. Found in hilly districts in Scotland, northern England, and Ireland, and may be had from the nurserymen. Then the Marsh Andromeda (*A. polifolia*), found chiefly in central and northern England, bears very pretty pink flowers, and grows freely in a bog or peat-bed. The very small English *Azalea procumbens* is also an interesting native, which some people try to cultivate, and where they succeed nothing can be more satisfactory, for the plant forms a cushiony bush not more than a couple of inches high. In Britain, it is found only in the Scotch Highlands. I have only seen this firmly established in cultivation once. Few people who admire what are called American shrubs can have failed to notice from time to time the beautiful St. Daboe's Heath (*Menziesia polifolia*), a plant found rather abundantly on the heathy wastes of the Asturias and in south-western France, and also in some abundance in Connemara, in Ireland. It is usually associated with American plants in our nurseries and gardens, preferring peat soil and the treatment usually given to such. It is an elegant and beautiful plant in every way, and should be in every garden. The flowers are usually of a rich pinkish colour, but there is a pure white variety equally beautiful, while quite distinct from the commoner. Grown in every nursery, from its great beauty, and therefore to be had without trouble. The very rare blue *Menziesia* of the Sow of Athol, in Perthshire, is also very desirable if you can get it, and I think it is sold in the Edinburgh nurseries. As for the Heaths, all are worthy of a place, beginning with the varieties of the common ling (*Erica vulgaris*)—the commonest of all heaths. It has “sported” into a great number of varieties, many of which are preserved in nurseries, and these are the kinds we should cultivate. Some of them are better, brighter, and different in colour; others differ remarkably in habit, some sitting close to the ground in dense, green, tiny bushes, others forming fairy shrubs of more pyramidal character, and all most interesting and pretty. These tiny shrubs and their allies in size might form a sort of edging or marginal line round a bed of choice shrubs planted in peat, as they frequently are and must be in gardens. I will merely mention the varieties *pygmaea*, *pumila*, and *coccinea*. Then we have the “Scotch heather” (*Erica cinerea*), the reddish purple showy flowers of which are very attractive, but far surpassed in beauty of colour by a variety of the same plant called *coecinea*; and there is also a white variety, as there is of *Erica tetralix*, to which is also closely related the Irish *E. Mackayana*, a plant named after Dr. Mackay of Dublin, who found so many of the plants in Ireland that connect its flora with that of south-western Europe. Next we have the ciliated Heath (*E. ciliaris*), a very handsome species, with flowers as large as those of St. Daboe's heath and Mediterranean heath (*E. carnea*), one of the most valuable of all hardy plants, in consequence of its blushing into masses of rosy red in our gardens in early spring. It is found in some of the western counties of Ireland, and of course after it had been discovered in other European countries. This forms a neat, low-lying shrub; grows on almost any soil, and is without exception the most valuable dwarf spring shrub that I am acquainted with; admirable for making an edging round a bed of choice shrubs, or anything else, for the rockwork or for the mixed border. It is now somewhat common to have ivy edgings round beds and borders; occasionally a desirable variety might be produced by making an edging of this plant, which, while it would form a dense evergreen margin at all times, would have the additional charm of flowering

beautifully in spring. There are several varieties, but the ordinary garden or nursery one is as good as any I have seen. Finally, we have among these interesting things the Cornish Heath (*E. vagans*), and from what has been said of the family it will be perceived that a very interesting bed or group might be made from these alone. Indeed, they would be most desirable to introduce everywhere that the soil is peaty or not over arid, and might be grown anywhere by excavating a bed and filling it with peat; but our great object should be to make the most of natural advantages, and as many readers of the GARDENER'S MAGAZINE must have gardens favourable to what are called American plants, they would find it worth while to devote a spot to the British Heaths and their varieties.

The *Pyrolas*, or Winter-greens, are charming native plants, some of them deliciously fragrant, and all interesting, but they are difficult to cultivate. *P. rotundifolia* and *uniflora* are among the best, and both are rare. Should any reader attempt their culture, it will be well to bear in mind that light free leaf-mould, with sand and a little good loam, are necessary: a light spongy sort of soil they delight in, with good drainage, abundant moisture, and shade. *Vinca minor* and *V. major* are too well known to need recommendation; there are now some finely variegated forms of the larger periwinkle, and a white-flowered kind of the smaller one is not uncommon.

One of the most precious gems in the British flora is the vernal Gentian (*G. verna*), which grows in Teesdale and in a few places on the western shores of Ireland. The blue of this flower is of the most vivid and brilliant description; it is in fact the bluest of the blue, and one of the most charming of all alpine flowers. Should be in every garden of hardy plants. May be grown well in sandy loam mixed with broken limestone or gravel, and indeed is not very particular as to soil, provided that it be kept moist, is mixed with sharp sand or grit, and well drained. A very important point in the cultivation of this plant is to leave it for several years undisturbed. It is best suited for a snug spot or rockwork, where, however, it should not be placed except where there is a good body of soil into which its roots may descend and find moisture at all times. It cannot be too well known that rockworks as generally made are delusions—ugly, unnatural, and quite unfit for a plant to grow upon. The stones or "rocks" are piled up, and no sufficient quantity of soil or any preparation made for the plants, so that all really beautiful rock-plants refuse to grow upon them, and they are taken possession of by weeds and rubbish, which indeed often refuse to grow upon the "rockwork," because they cannot lay hold of it, so to speak. They are generally made either too perpendicular or too ambitiously even in the best gardens in England—masses of rock used merely to produce an effect, or masses of stone piled up without any of those crevices or deep chinks of soil into which rock-plants delight to root in a native state. The right way is to have more soil than "rock," to let the latter suggest itself rather than expose its uncovered sides, and to make them very much flatter than is the rule, so that the moisture may percolate in every direction, and that the rockwork may more resemble a jutting forth of stony or rocky ground than the ridiculous half-wall-like structures which pass as rockworks in this country. I have grown this *Gentiana verna* very well in well-drained pots, with plenty of water in summer, and also in the open border in fine sandy soil, the surface being studded here and there with small stones, among and around which this lovely plant made its way and flowered "deeply, darkly, beautifully blue" every season. It is abundant in mountain pastures in central and southern Europe; it is, in fact, a true alpine, and may be had in nurseries, particularly in Backhouse's Nurseries at York, which contain the most interesting and beautiful arrangement of plants I have ever seen in any garden, public or private—a noble and naturally-arranged rockwork, exhibiting in good health most of the rarest and beautiful alpine plants yet discovered. It is better worth a visit in spring or early summer than any other garden scene I am acquainted with. The Marsh Gentian (*G. pneumonanthe*) is also a lovely plant, more so perhaps than many would think this dull climate capable of producing. It should have a moist spot in a border, and is not difficult to find in the north of England, and also grows, though less plentifully, in central or southern England. The Brighton Horticultural Society is in the habit of giving prizes for collections of wild plants, and thereby doing much harm by causing a few rude collectors anxious to win a few shillings to gather bunches of the rarest wild flowers, and perhaps exterminate them from their only habitats. When at one of its meetings two or three years ago, I observed among the collections competing for a paltry prize large bunches of this beautiful gentian, which had been pulled up by the roots, to form one of one hundred or more bunches of wild flowers, by some wretched Goth who happened to know wild flowers. To exhibit our wild flowers at a "flower show," where they are contrasted with hosts of geraniums and loudly coloured flowers, is a very doubtful way of attracting people to study them; but to so arrange matters that the rarest plants of a locality are pulled up, and perhaps exterminated, to form one of a

collection of this kind, is the "unkindest cut" that can be given to our choice woodland children. Indeed, in such positions the flowers are not likely to be admired except by those who know them, and they must be pained to see them in such a position. Therefore the system is bad, root and branch, and should be discouraged by every lover of wild flowers, as well as any other plan that would cause quantities of the rarest to be pulled up or otherwise exterminated.

CYPRIPEDIUM CALCEOLUS.

ON HAYMAKING.

Paper read by A. H. GRIFFITH, Esq., at the monthly meeting of the Ballymahon Farmers' Club, on the 7th of June.

The animal world is in a continual state of change, and the relative proportion of the substances of which it is composed is variable, and new combinations are continually being produced. Hence, animals may at one time be fit for a certain use, for which, before and after, they were unfit. Every object in nature has a beginning, a middle, and end; and in human beings this beginning, middle, and end become youth, puberty, and old age. In youth, the muscles, bones, and sinews of animals are soft and pliable; in middle age, less strong and firm; and in old age they become tough and hard, and lose that suppleness and elasticity which they possessed in youth. The flesh of young animals, therefore, is tender and sweet, and is in general so in proportion to the delicacy of the materials upon which it is reared. Human milk, for instance, is of richer ingredients than that of any of the lower animals; and hence a New-Zealand savage prefers the flesh of her offspring to anything old or tough. We ourselves have a similar predilection for young beef, which is tender, firm, and strengthening, whilst we know old beef to be manifestly the reverse. In fact, old age or natural decay is in mankind caused by a gradual ossification of the system—that is, by the sinews and muscles losing that pliancy and elasticity which they possessed in youth, and becoming tough and hard. Modern investigations in vegetable physiology show also that the several tribes of grasses are likewise to be recognized as living beings. These also have their stages—they have their "exit and their entrance;" and the analogy between the animal and vegetable creation is every day shown to be more close. If the flesh of old cows and sheep be distasteful, as they certainly are, to us mankind, most assuredly so are old grasses to the grazing animals. The rule, therefore, is—*young food is good and nutritious, old food bad and unwholesome.*

The question, then, to be determined is, What is young food and what is old food? Where is the discriminating point at which the various sorts of food are in their best and most prime condition? This point of time would appear to be that at which the vital energies are fully developed for the propagation of the species. This is the point at which I consider animal food to be in its prime; and from the same point vegetables and the various tribes of grasses begin to decline in nutritive value. When vegetables are required for food, therefore, they are universally used before propagation commences; so are, generally, the grasses (and unquestionably it is at this stage that grasses are most relished by animals); for in every pasture cattle most eagerly devour the younger grasses, and leave the older patches behind them; and the great point to which I would direct attention is, that in cutting grass for hay the same rule should be remembered, and that should *food* be the principal object in view, the grass should be cut down *before* the time of the full development of the seed, as the grass is then in its most perfect state, and flowing with milk and nourishing juices. After that period future efforts will be directed, not to its own preservation, but to transfer all these, its constituted principles, into seed, for the propagation of its species, which, when done, the stalk consists chiefly of woody matter. For instance, the stalk of wheat in youth is soft and pulpy, and flowing with a sweet saccharine matter; after the period of ripeness—that is, in old age—this stalk becomes again hard and dry, and turns principally into wood, which is the principle in plants analogous to bone in animals. It is commonly but erroneously supposed that plants when perfecting their seeds draw a great deal of the richest material, such as phosphate of lime and phosphoric acid, from the soil: they do no such thing; but their own life being now perfected, their energies are directed to transmute their own juices and substances into these ingredients in the seed for the propagation of the species, and this being done, their work is finished, and they die after the operation. The seed also itself becomes deteriorated as an article of food when allowed to become over ripe. Take the grain of corn, for instance—when come to its perfect size it is then at maturity, and is pulpy, soft, and milky; but when it is allowed to be over ripe, so as to fall, through old age, from the stalk, as in shedding, this pulpy soft substance becomes changed into a hard and bony one—in other words, the fine flour of the grain is transformed into the hard rind which constitutes the rough substance of bran. From this reasoning and philosophy of the question, therefore, I would induce the following practical rule:—When any of the various tribes of grasses are intended as food, they should be cut before the ripening of the seeds, and even before the seeds are fully developed. As to the mowing and saving hay, the routine is pretty well understood; I may observe, however, that the meadow should be cut close, for one inch of the bottom will weigh more than two at the top; and there is a still greater advantage by so doing in the aftermath, for the portion that remains quickly dries up and decays. As to the saving of hay, it requires frequent turning and exposure to the sun and air, which can be well performed by the hay tedders now generally in use. Before the dew falls, the hay should be gathered into windrows and cleanly raked, and on the second and third days these operations, with some slight variations, should be repeated. Should the weather permit, if carried to the hay-yard and ricked without tramping in the field, it would add much to the nutritious qualities of the hay, and save considerable expense and waste; but to effect this it will be necessary to be provided with a good rick cover, and the necessary apparatus for elevating the canvas sufficiently high to allow the free escape of any moisture arising from the slight fermentation that must necessarily ensue from even the best saved hay. The expense of making into field-cocks, the loss from exposure, and rotten tops and bottoms, would be thus saved; and this loss, though in general not much thought of, makes a considerable item in the farmer's profits and losses. Having now got the hay into the hay-yard, my task is nearly accomplished, but it still has to be put together with care, slightly salted, and well preserved from the weather by thatch. Our present experience should teach us the value of well saved hay in large quantities, and prove the correctness of the adage—that old hay is old gold.

NOTES FROM A TOUR THROUGH KENT.

THE SEAT OF COLONEL LOYD AT HAWKHURST.

Hawkhurst is a decayed market-town, most pleasantly situated about fifteen miles from Tunbridge Wells, and is surrounded by many charming seats of the nobility and gentry, and not the least interesting amongst them is the one above named. In fact, when looked upon from a gardening point of view, it is far superior to any I have yet seen in the same county; but then it must be understood there are many which I have not seen, and the comparison is therefore partial. But the superior condition of everything in this place speaks not only in decisive language in the highest praise of the worthy proprietor's liberality in all that pertains to gardening, but every step we take increases the force of the original conviction that all the details are managed by a master mind. More I need not say on that head, as Mr. Record, the able gardener, is too well known in the horticultural world to need any further eulogium from me; so I shall proceed to furnish my notes from this place in the order they were taken. In the first place, we enter a range of three vineries, ninety feet long; in the earliest was a magnificent crop just on the point of colouring, the crop was very evenly distributed, the bunches of extraordinary size and well shouldered, and the strength and vigour of the growth was all that could be desired. Indeed, such another display of grapes, combining all the essential features of health, strength, and vigour, I have not seen in any other house this season; and whatever may be the conditions under which they were grown, their appearance fully justifies me in saying they were evidently managed with skill and judgment. Unfortunately, some men will not be benefited by the experience of others, and so they continue on in their old track, always meeting with disappointments, and wondering why they fail under circumstances similar to others who succeed so well. As an instance of the self-will of some men, I will refer to the common practice of covering the whole roof of a house with a mass of leaves and wood, so that neither sun nor air can exercise its beneficial influence upon the vines as it should do. I have seen so many instances of this, not this season only, but in previous years, that when I have the good fortune to meet with such an able cultivator as Mr. Record, I feel that when inspecting his noble crops, grown on the one rod to a rafter system, that I can breathe freely, and can converse with him without feeling I shall offend my friend by advocating space, to secure light and air for the full development of all parts of the vine. As above stated, the vines are grown with one rod to a rafter, so that the single rod has the whole space of a four-foot light to expand itself upon. How different is this from those houses where we find the fruiting rods placed only at a distance of eighteen inches to two feet apart, and when they develop their leaves the whole aspect of the house is dark and shaded, rendering it more fit for ferns than grapes! Such is the condition of many, yet the success of others who adopt the more liberal view of what constitutes first-class culture, is not enough to convince the advocates of the close-rod system that they would secure a finer quality, and an equal quantity, if they were to allow their vines sufficient space for the proper development of all their parts. The above remarks respecting the early vinery here will apply with equal force to the second and third, for they were alike vigorous and abundantly fruitful. In the second vinery was that useful grape the Marchioness of Hastings. The others consisted of Royal Muscat, Black Hamburg, and Muscadine. In the second vinery I noticed a magnificent show of late strawberries, and standing in a 20-inch pot was a fig-tree with no less than 350 fruit fast swelling off. In one of these houses I also noted a choice collection of the best varieties of camellias just completing their growth.

The admirable system of ventilation of these houses is worthy of a special notice, as it is one of the most complete of all the contrivances I have yet seen; the whole top lights of a house being all moved up or down at one time simply by the turning of a small cog-wheel, which is worked by a winch about three feet from the floor of the house. The main features of the plan consist of two cog-wheels working in the manner they usually do, one within the other; the smaller one is revolved by the turning of the winch or handle, and as this revolves it works within one a size larger, which has connected with it a perpendicular iron rod from the roof of the house. As this rod also revolves from the same action, as also does another running lengthways of the house, some small chains which encircle this rod are fixed to the lights, and as these chains are gathered up or let out by the revolutions of these rods, air is admitted to any extent the whole length of the structure. I believe this is simply called "Weeks's cog-wheel system;" but by whatever appellation it may be known, it is a commendable piece of ingenuity that ought to be extensively patronized. To show, too, the superior fitting-up of these houses, and the convenience with which they can be adapted to many useful purposes during that portion of the year when more room is required, and when the houses full of plants would do no harm to the crop of grapes, I must allude to the temporary stages that can be put up or taken down at pleasure. These stages consist of breadths of wood trellis-work, well made and painted; they are made in breadths from three to four feet wide, and these are placed during the winter season upon trestles, so that the body of the houses can be filled with plants, these plants enjoying at the same time a full exposure to light. When the time comes that these stages must be removed the trestles are taken away, and the trellises laid down upon the floor of the house, thus securing a comfortable footing, and allowing at the same time plenty of space for those operations which are necessary in all cases of grape culture. We have long since had an objection to fixing permanent stages in vineries, because they always hold out an inducement to use them when, strictly speaking, the vines ought to have the benefit of the whole house, but we never saw a better means of getting over the difficulty than this now alluded to.

It is now a pleasing task to refer to an excellent set of pot vines, twelve in number; these were bright examples of horticultural skill. They were trained to a flat circular surface about three feet over, many of them bearing handsome bunches of delicious ripe fruit, and considering the early season of the year (as previous to my visit Mr. Record had been cutting some eight or ten days) they were very beautifully coloured. The sorts were chiefly the Black Hamburg, the Sweetwater, and a magnificent example of the Mill Hill Hamburg. This last is a noble subject either for pots or for borders, and, as probably some of my readers will remember, a special favourite of mine. The talented gardener here had done it full justice, for both the bunches and berries were remarkable for size and finish. Our friend had also amongst them one plant of the Muscat Hamburg, and although slightly given to shanking, in this instance I am compelled to acknowledge that it was exceedingly well done; for we are not

accustomed to see this grape in fine condition, although when well done it is a valuable variety. There was also a very promising lot of young pot vines for next year's crop. This range of houses and some adjacent pits are heated by one of Weeks's tubular boilers. In these pits we noticed a batch of Beaton's geraniums; they are intended to be grown as standard and half-standard specimens for conservatory decoration. I have no doubt, from the vigorous habit of some of them, they will prove suitable subjects for such work. In the same range was also a fine batch of chrysanthemums already in an advanced stage of growth, and if the same liberal culture is carried out as hitherto, they will make monster plants by the autumn. Near here we saw a fine crop of melons, very healthy and clean; the variety was the Conqueror of Europe, an especial favourite with the family.

We come next to the cucumber house and stove, forty feet long; these are span-roofed buildings, of excellent make and admirably arranged. In the stove we found a good selection of choice plants for dinner-table decoration, and many other useful subjects, including a fine plant of *Oncidium flexuosum*, with two spikes of flowers just beginning to expand, and another with one spike. Of caladiums there were some useful varieties, with a charming plant of the *Cyperus alternifolius variegata*, and also the green form of the same *Cyperus*. One of the most vigorous stove plants I saw here was the *Allamanda Schottii*; it had made a vigorous growth quite six feet long. Then there were numbers of that useful winter-flowering plant the *Sericographis Gbiesbreghtiana*, and some healthy well grown exotic ferns.

In the cucumber-house the only varieties were Monroe's Rabley, an excellent bearer, considered by Mr. Record to be the best, and Stanley's Prolific. Both were good, and in a thriving condition. We next enter a large span-roofed plant-house, 50 feet long and 20 feet wide; this is but a short distance from the stove, so that these are all heated by a 42-inch saddle boiler. The first thing that attracted my attention here was a splendid lot of specimen fuchsias for late summer display. These were exceedingly well done, as also were some specimen plants of the show-class of pelargoniums. Many of these would measure more than 3 feet through; they were in the finest possible health, and the first batch just coming into flower, while the successional lots were equally clean and healthy as the preceding. Beside these there were huge pans of *Achimenes* in great variety, and bearing unmistakable signs of superior culture. It is many years since I have seen the *achimenes* so well done as they are here, and it is evident they are well understood; for instead of being drawn up in the confined atmosphere of a stove, as they often are, they enjoy a full current of air in this cool house, and their condition at the time I saw them (May 11th) was such that no one could gainsay the correctness of the treatment they were receiving. In close conjunction with these were six noble plants of the tree mignonette, with clean straight stems 4 feet high, and heads, not trained out, 18 inches through. The seed was sown in the second week of August last year, in small pots, and they were repeatedly shifted into every successive size pot until a few days before my visit, when they were potted into No. 10 pots for next winter's flowering. This is an admirable plan for growing mignonette where any quantity is required for cuttings from; the plants under notice were trained to neat single sticks, with all laterals pinched off as they appeared on the stem.

Amongst great numbers of bedding plants, I noticed a fine lot of the *Centaurea argentea*, that beautiful white-leaved plant so much used for bedding. In making inquiries as to how so great a stock had been got up, Mr. Record told me he had struck them chiefly from leaves; in this way they will, he says, strike readily if well watered when put in, but they should receive no more until they are rooted. Of Mrs. Pollock geranium there were some 300 strong plants to go out; and of such things as *Verbenas*, *Heliotropes*, &c., there were vast quantities, in a fine hardy condition. Before I leave this portion of the grounds, it will be a pleasing duty to refer to the cottage specially built for the young men's bothy. I have the greater pleasure in doing so, because this is one of the very few instances where the comfort of the young men is at all studied; but, thanks to the liberal owner of this beautiful spot, for once in our lifetime we are able to say this is an instance where not only comfort has been aimed at and attained, but a corresponding amount of anxiety is manifested that it should continue to be what it professes to be—a comfortable home for the men; and, if I may judge from the clean well-furnished apartments of this pleasantly-situated cottage, I should say both the worthy owner and his gardener have been equally anxious that every needful comfort should be supplied. Without having any pretensions to elaborateness, the whole thing is so complete that many an industrious mechanic may be pardoned if he should feel a spice of envy against those who occupy such a home. What makes this still more valuable to the young men is the fact that they are not called upon to act as cooks and housemaids for themselves, as a woman is engaged to do all the necessary work of the house. How different are these clean well-ordered rooms from those too often met with in those back lean-to places where the sun never shines! for it is a notorious fact that in many other well-arranged gardens the young men's rooms are by no means habitable, much less are they healthy; for we generally find them crowded into some odd corner under the shade of a north wall or some other building, or next to a dusty sulphurous stoker, where the rays of the welcome sunshine can never find their way. By whose suggestion this excellent provision was secured in the place under notice it was no part of my business to inquire; it was sufficient for my purpose to see that it was really provided; and here I will leave the matter, with a sincere wish that those who profess to do so much for their young men will not be less liberal than the worthy owner of these beautiful grounds.

I must now proceed to notice the more ornamental portion of the grounds. The position is a delightful one, with a noble mansion standing upon a slightly elevated position, commanding extensive views over one of the most fertile parts of the county of Kent. Standing at the extreme limits on one portion of the estate, there is a fine stretch of country extending, I should judge, to many hundreds of acres of the same property, and this beautifully wooded, and an undulating surface that always adds charms to the scene. The mansion is approached by a neat entrance-gate from the main road leading from Hawkhurst to Hastings; the carriage drive is of ample width, and there are many fine belts of shrubs and trees that give a character and richness as the visitor wends his way to the principal entrance of the house. In passing on thither I noticed a fine *Wellingtonia gigantea*, 16 feet high, and beautifully furnished to the bottom; also noble examples of the *Deodara* and other conifers. It was in passing here that we saw in the distance, in a lovely valley in the park, a fine sheet of water of several acres in extent. This proved, as we became

better acquainted with the place, to be a grand feature, as it added change and variety to what was already a delightful view across a wide expanse of country.

Surrounding the more private apartments of the mansion is a noble terrace and a tastefully-designed flower garden, with a fine conservatory looking down upon the whole. The conservatory we found well furnished with a miscellaneous collection of plants, and amongst the many fine creepers I noticed that grand old subject the *Acacia grandis*, and several varieties of *Passifloras*, with their graceful pendulous branches; but still more attractive were some exquisite small specimens of *Azaleas*; they were perfect models of perfection in every way, being literally covered with flowers from the rims of the pots to the very tops of the plants. Amongst them was a very pure white; the name of this variety was Louise Margottin. *R. inc. des Doubles* was another fine flower, of good substance, a semi-double flower, in the way of *Rubens* as to colour. There were also some well-grown and handsome *Pelargoniums* of the fancy class.

In the flower garden, upon the terrace previously alluded to, there were some cheerful effects of spring gardening, which is carried out here to a considerable extent, as there were beds of the blue and white *Forget-me-nots* (*Myosoti-*) in full flower, also the yellow *Alyssum saxatile* and the white perennial *Candytuft* (*Iberis sempervirena*). Besides these, a great variety of small hardy shrubs were brought into use, as also were all the *Cliveden* pansies, and several varieties of daisies, as well as hyacinths and crocuses, and other spring-flowering bulbs. The effect of this was that ever since the first week in April the garden had been gay with brilliant colours. The next striking feature which arrested our attention was a group of twelve pyramid *Laurestinus*, standing in slate tubs by the side of one of the main walks, as we were coming down from the terrace into the pleasure grounds below. These had stood the late winter unharmed; but I should remark, that, by a clever piece of ingenuity of the able gardener, these slate tubs were sunk into the earth up to their rims during winter; and by having neatly out slabs a little larger than the holes required for the tubs, the tubs are lifted out in the spring and then the stones placed over the holes, thereby securing a foundation or bottom for the tubs to stand upon during summer. This is far more convenient than having to dig out fresh holes every winter, and to fill up the same again in spring. Our next movement is to inspect the grounds more distant from the mansion. The extent of the whole of the pleasure grounds is about twelve acres. There are many delightful walks and shady bowers, and as our steps are directed to the south-west extremity of the grounds, we come quite unexpectedly upon a lovely dell or wilderness, which we find rich in subjects adapted to such a quiet corner of repose. Peeping out amidst a perfect thicket of foliage, upon a yonder bank, is the yellow wild broom in all its glory, and here and there a *rhododendron* lighting up the scene where we least expected to find it; still farther on, dipping gracefully down to the water's edge, are to be seen various forms of the vegetable world, that give to the place a rural and retiring character. By another path we are brought in full view of a rose-garden and an American garden combined. But I must not stay here longer than to say that the collection of roses consists of no less than three hundred and twenty varieties. From this spot we are taken to inspect the orchard and kitchen garden, both of which are new. The former we found well stocked with trees grown in the pyramid fashion, and the kitchen garden well and judiciously occupied with such crops as are always in great request for a first-class table. As a closing paragraph to these notes, I would wish to remark on the neatness and the order which prevailed throughout the whole place; and the least I can do is to thank Mr. Record for the courtesy shown me, and to assure him I shall cherish for many years to come, if I am spared, the remembrance of my visit to Hawkhurst.

J. C. CLARKE.

GARDENERS' ASSOCIATIONS AND THEIR OBJECTS.

I am induced to occupy a space in the pages of this Magazine on a subject which has for many years past engrossed my attention on every opportunity that has presented itself. A few months ago I was solicited by some of my brother gardeners to assist in the re-formation of a society which should have for its object the mutual interest of our fraternity, by endeavouring to secure a fair remuneration for our labour and skill equally with other operatives and artisans. Combined with this was to be mutual edification, by exchange of opinions on subjects connected with our daily practice.

Well, this society was formed at a public meeting, over which our worthy editor presided, and the attendance was on the occasion very good, and upwards of twenty gardeners and employes paid their first quarterly subscription the same evening; the scale of contribution being fixed at as low a charge as it possibly could be compatible with the solvent working of the society. Of course there was the usual clique of discontents, who could see no good resulting from such an association unless it directly aimed at a combination for the advancement of wages. They could not perceive that any other benefit was to be derived; or rather they affected to treat with contempt anything that approached mutual instruction. To this latter remark allow me to add a word, and that is, that there is no class of artisans that are more indebted to local influences for their daily success, practically speaking, than gardeners. Let us only cite one illustration among the many we could recite confirming its truth. Let a man acquire a knowledge of his profession in the south of Devonshire, and then afterwards be called on to exercise it in the northern districts of the same county, and what would be the consequences? Why, he would find himself beset with difficulties which never occurred to him when residing in the southern part of the county; and why? Because the climate in the north of Devon is as different to the south as if there were many degrees of latitude between them. Now here is a proof of one of the most material advantages that must result from mutual intercourse on gardening. We are often, owing to circumstances over which we may not have immediate control, called, after a long continuation of practice in one locality, from that to another far distant. There is also another favourable circumstance, which should not be overlooked by those who feign to despise mutual associations, and that is, many of our difficulties in gardening operations are greatly lightened by meeting with employers who are ever ready to open their purse, either to purchase plants or to afford us every desirable requisite for promoting their cultivation. Having myself experienced both sides of the question, I am prepared to say that gardeners should cautiously avoid a crying evil which unfortunately prevails to a great extent in our profession, and that is, of being too apt to condemn the practice of others without any consideration as to the demands on their time, and the extra efforts they have to make to comply with the tastes and gratify the desires

of those by whom they are employed. Again, the criterion of a good gardener is not to be measured by what he exhibits, or the number of prizes he may gain at a horticultural exhibition, but by a neat and well-kept garden, and a constant but regular supply of all kinds of floral and horticultural products, indoors and out. This, then, brings me to the after-part of my subject, in relation to gardeners' associations for mutual advancement. Now all those combinations may do much to assist, or rather to help us on to the gaining of those wages which we are fairly entitled to, yet they should not form the medium by which intimidation is to be held out to employers; for we must not forget that in a degree we are not a necessity, but a luxury. Although we are somewhat an indispensable appendage to an establishment, yet we can, in many instances, be dispensed with. If we are aiming to exalt ourselves, with the view of obtaining a better remuneration for our services, it must be by a careful study of our habits, avoiding everything that has a vicious tendency, valuing the time of our employers at all reasonable seasons; and then the more intelligent we become by seeking to expand the mind in acquiring every information in connection with our profession, depend upon it, the more thoroughly shall we be appreciated, and the more liberally rewarded. It is a lamentable fact that very many of our young men seek, as a stepping-stone to their advancement in the profession, the notoriety of having served in a titled gentleman's establishment. There can be no greater fallacy attached to a young gardener's ambition. If the mind be cultivated, the rest may follow as you can best obtain it. Lately, in the course of my conversation with the head-gardener to a nobleman near London, I asked, "What gardening literature do you subscribe to, or, rather, read?" "None," was his reply. Well, I cannot say that I despised his contracted opinion, but I felt it a pity that he should be devoid of that ennobling ambition which leads a man to acquire a thirst for a knowledge of all that is daily occurring in connexion with his means of subsistence.

Having said this much on the mutual benefit of gardeners' associations, a word to those who readily take office, or who are anxious for their formation. Let them not forget that when they have undertaken their part in guiding the helm of its affairs, that they have incurred an individual responsibility, though it may be voluntary. The fulfilment of such duties they should not shrink from by mere off-hand excuses. They must not expect the secretary to maintain its attraction if they are not at their posts to give him a helping hand. The downfall of all societies in connexion with gardening may be traced to the apathy felt towards its workings by those who expect great things of others, but little of themselves beyond applause. Let us one and all, in the promotion of any good object, be actuated by the same desire that influences our great commercial community,—a scrupulous regard for time and the fulfilling of our engagements. Then may our gardeners' societies become, as they ought to be in every town and village where horticulture is patronised, integral parts of the permanent institutions of our land.

JOHN F. McELROY.

BROWN'S FRUIT GATHERER.

In picking fruit-trees the danger of climbing and of ascending ladders detracts much from the pleasure. To be sure, "when the pear is ripe it will fall into our hands," if our hands are in the proper position. But in the engraving is shown a very simple fruit gatherer, by which one may stand on *terra firma* and exploit the denizens of the orchard. It is merely a bag for the reception of the fruit secured to a pivoted frame of wire, which, when the cord is pulled, closes against the edge of a curved plate. The operator holds the staff to which the apparatus is fixed in one hand, and pulls the cord which operates it with the other.

Placing the aperture so as to envelop the fruit, he merely pulls the cord, when the fruit is separated from the branch and drops in the bag. For the picking of fruit designed to keep, much care is required, and those which fall to the ground by the force of the wind or the violent shaking of the tree are almost always more or less injured. In raising fruit for market these injuries are elements of deterioration, and the fruit—whether apples, pears, peaches, or high growing and lasting fruits—should be presented to purchasers in the best possible state. To secure these results is the design of the inventor, Mr. Wm. Brown, of Worcester, Massachusetts, who patented his invention Feb. 5, 1867.—*Scientific American*.

THE STAPLEFORD TULIPS.

On the occasion of the last exhibition at Cambridge, I accepted an invitation from Richard Heady, Esq., of Stapleford, to pay him a visit and have a day amongst the tulips. I accepted the invitation, of course, and I never in my life had a more agreeable time of it in a visit to a garden anywhere. None of our readers need be told that Mr. Heady is the most experienced, most successful, and most eminent florist in Britain; for his name is on the roll of those who have attained to honours by talent, perseverance, faithfulness, and the constant exercise of a gentlemanly generosity and an unflinching public spirit. His name is in all the catalogues, in all the pedigrees, and all the canons of the florists; and so long as floriculture shall be pursued the evidences of the influence of his work in its promotion will be seen in the characters of flowers and the principles of judging them, and possibly also in their nomenclature. I met at Stapleford Mr. George Lightbody of Falkirk, a veteran most of all worthy to be spoken of on the same day as Mr. Heady, and Mr. Sharp, of Birmingham, an amateur possessed of a truly catholic taste in all that relates to flowers, colours, pictures, and art generally. If a man pretends to understand flowers, and avows that he does not care about pictures, or shows an indifference to art, I never believe in him; I feel certain he will break down somewhere, so I should never ask such a man for an opinion of a flower which I could not see and judge for myself. One of our best pleasures during our stay at Stapleford was that of criticising Mr. Heady's pictures, and finding that the same rule holds within as without this charming residence,—the rule that whatever is tolerated must be of its kind good. To see Mr. Heady drag out a tulip that he does not like, and "stamp it out" there and then, is something to remember. If he came to the conclusion that any of his pictures were bad, I believe he would have a fire lighted on purpose to pile them on it and make an end of them for ever. The rule that everything must be good is illustrated in every part of the establishment; you see nothing but what of its kind is perfect; and Mrs. Heady follows the rule religiously, and ministers to her guests a splendid hospitality. The first hint I obtained of the interest attaching to Stapleford was when dressing for breakfast on the morrow of my arrival. I looked out of window upon a pretty breadth of lawn towards a half-weeping copper-leaved beech-tree of the most beautiful proportions, and intensely rich in colour. Glancing round, I was presently startled to see Moutan pæonies a yard high and two yards through, leafy enough to hide every particle of stem, and appear like mounds of vegetation, and covered all over with gorgeous flowers of various colours, those which took my attention most particularly being of a soft lilac rose or pink with shades of purple. A considerable time elapsed ere we got a peep at the tulips, and we seemed to be in no hurry; for on every hand, as we roamed about the garden, we found something to admire, something to inquire about, something to illustrate theories and doctrines in which we have a common interest. The tree pæonies we found to be a special feature of the garden, and our host, the passion of whose life is and has been the raising of new varieties of flowers susceptible of improvement, has been a careful breeder of these things, and has originated some that in due time will no doubt become famous. There is one, at least, amongst his seedlings that is as novel as it is beautiful. It bore no flowers and needed none, for its leaves are margined with red, buff, and orange-yellow lines, and at a moderate distance its appearance is most beautiful and novel, calculated to prove an object of attraction and admiration to the most careless rambler in a garden. Florists' flowers are Mr. Heady's chief delight; but we find here beautiful coniferous trees, such as Wellingtonias, *Picea amabilis*, *nobilis*, and *nordmanniana*, with trees and shrubs of all kinds, and a considerable variety of the best hardy bulbs and herbaceous plants. There are vineries, peach-houses, a pine stove, and a range of plant-houses containing collections of geraniums, *calceolarias*, and, in fact, hard and soft wooded plants of all kinds. Whatever admits of improvement as a subject for the hybridist and cross-breeder meets with especial attention, and hence many of the finest specimen plants we meet with in the houses are seedlings belonging to the place, and mark the point Mr. Heady has attained in the improvement of that particular subject. Mr. Heady usually contributes from six to twelve van-loads of plants to the Cambridge shows, and is quite hardened to the sensation of taking first prizes; so it would be superfluous to say that specimen growing is carried out with spirit, and that if we had time and space we might occupy it profitably in a description of the place and all its belongings. But we must hurry on. When we quit the pleasure-garden, we come upon various plantations and frame grounds. We find a bank of potatoes—they are of course seedlings of Mr. Heady's; and we fully believe him when he says he has amongst them some of the finest ever raised. He wanted some good *Gladioli*, and bought the best that were to be had. But none of them were good enough; so he set to work in cross-breeding and originated a new race, and here are the seedlings in quantity, growing into money, and destined no doubt to make a figure in our lists hereafter. Next, we came across a great batch of Pinks, Carnations, and Picotees. Next, a collection of Auriculas; at another turn, *Ranunculuses* and *Anemones*; and so we go on, and so we go on, until we gather together in a tiffany-house, and find the ground covered with an immense assortment of the best bedding plants, all in an enviable state of health and vigour. As tiffany-houses are not everywhere a success, we are bound to say that this one is about 40 feet long and 16 feet wide, as sound as if built and covered in but yesterday, yet bearing the marks of many years' wear and tear; without question one of the cheapest and most useful structures in the place, and especially adapted, in the cold climate of Cambridge, for hardening bedding plants prior to planting out. At last we got amongst the tulips, the best two beds being side by side, under canvas of course, the edges of the beds being formed of *Spergula pilifera*, in place of the usual plank-on-edge support, and plenty of room in the walks between and around for a party of connoisseurs to move freely and compare notes on the flowers. I cannot hope to convey any idea of the magnificent spectacle which these two beds presented on the 24th of May when I saw them for the first time, though they were then a few days past their best. Here and there a showy breeder had got in—rogues are to be found in the best of company—and these appeared to serve just the same purpose as judiciously managed discards in music, that of heightening the general effect. We made about six separate inspections of these beds, at each time instituting a few comparisons, or assisting in the bestowal of names on flowers that were considered entitled to such an honour, and at every opportunity making notes to keep all worthy matters in remembrance. Mr. Lightbody and Mr. Sharp became more and more enraptured, and at last appeared to be afflicted with a solemn frenzy; for they had not a word to say, but were going from flower to flower, not, like bees, with a merry hum, and in the conviction that sweet stuff is the alpha and omega of existence, but with signs and motions indicative of surprise, delight, wonder, and curiosity. At this juncture Mr.

Heady pulled me by the sleeve, as if very anxious I should be kept from participating in the fanaticism of which we saw the slow but sure beginning, and said, "Come down to the orchard." So to the orchard we went, and found it a very nice orchard, but somewhat hurt by the cutting close by of the Great Eastern Railway, which has so drained the moisture from the soil that many kinds of fruit-trees that used to thrive on the ground have ceased to be capable even of keeping a few green leaves upon them. Here we found the kidney beans and the potatoes cut off by frost, and other things more or less the worse for it. A strip of *Bromus schraderi* had a very thrifty look; it had been cut once already, and on the 24th of May was nearly ready to afford a second cut. Mr. Heady says his horses eat it greedily, and he has great faith in its feeding properties. But the best sight here was a bed of breeder tulips, about 250 long and five feet wide, all of them in batches of one colour, as, for example, fifteen to twenty feet of bright rose, next a similar extent of purple or brown, next yellow, and so on throughout, the effect being that of a most gorgeous example of bedding: and why late tulips are not used for splendour in May, and in composite groups, so as to produce bedding effects, without reference to the rules of the florists, appears to me to be one of those negative facts that a positive philosophy is quite incapable of resolving into its primal elements. To say that these breeders are good, is to talk as absurdly as the man who avers that the sun is bright, and will swear to it if he be needful. The truth is, these breeders are as far beyond all ordinary tulips in quality as ordinary tulips of the florists' section are in advance, in respect of beauty, of the wild tulips from which they have been bred. For size, symmetry of form, and substance and purity, I believe they cannot be matched in England; and it would be absurd to talk of Holland, for the simple truth is, the Dutch know nothing at all about tulips. Many and wondrous as are the named varieties in the Stapleford collection, no one competent to form an opinion on the subject can doubt that as many fine flowers may be broken from these breeders as the collection comprises already; and it is but proper to add that Mr. Heady grows very few indeed except varieties of his own raising. Mr. Lightbody told me he had been accustomed to see a bed of breeders here about 400 feet long, and containing nearly 18,000 bulbs. Of course we found many of them breaking, that is, changing from the self or breeder state to the variegations of colours which are denominated flames and feathers, but we made no search for select breaks; that is a task for Mr. Heady in his quiet hours, when he can exercise his rare and ripe judgment without bias. I will now gather together the notes I made during a series of inspections of the best beds, feeling quite sure that, though the subject may be destitute of interest to many of our readers, the few faithful florists that remain to illuminate the world will be pleased to have a record of the state of things at Stapleford in 1867, the more especially as the Magazine is now the only medium for such communications, the exclusively floral periodicals having all perished.

DESCRIPTIVE LIST OF A FEW OF MR. HEADLY'S TULIPS.

R. Rose, Bi. Bizarre, By. *Dyblemen*. The figures denote the row to which the variety properly belongs.

Adonis, By. 4.—This is pretty well known as a splendid and most constant feathered *dyblemen*, and it is frequently described as from the same breeder as John Linton, which is sometimes flamed, and sometimes feathered and flamed, whereas *Adonis* never flames, but has an elegant pencilled feather. John Linton opens creamy, but soon becomes pure; *Adonis* is pure from the first. It is quite likely that if not from the same breeder, they are from the same pod of seed; this appears to be the opinion of both Mr. Heady and Mr. Lightbody.

Alma, By. 1.—Medium size and perfect shape, grand purple flame; sometimes the flame is quite black. Purity *sans reproche*.

Apollo, Bi. 4.—Rather short cup, but bold and finely finished; rich crimson flame.

Arethusa, R. 4.—Large, superb shape, stout, pure; narrow lake feather and flame of rich crimson. A most beautiful flower.

Blind Bonny, R. 2.—In form and purity unsurpassable, and the substance extraordinary. If there is one quality more than any other that distinguishes the Stapleford tulips, it is a leathery thickness of petal; but they are wonderful in quality every way. This flower has a narrow dark carmine feather.

Captain Hodson, Bi. 3.—Fine form and stout petals, brilliant gold yellow, feather and flame of fine dark brown, the marking very regular.

Cedo Nulli, R. 1.—Fine form, rosy scarlet feather.

Circe, R. 1.—Splendid flame and feather of deep crimson; a gem of the first water.

Comet, R. 2.—An enormous flower, with broad crimson flame; fine.

Commodore, Bi. 3.—Fine form, broad petals, ample purple beam and narrow feather. Quatering out of the question.

Delight, Bi. 2.—The form is first-rate, and the substance remarkable. Ground colour bright yellow, with fine black feather; in purity perfect.

Demosthenes, Bi. 3.—Fine form and substance, quite pure, fine dense feather, quite surpassing Platoff and George Hayward.

Duke of Leeds, Bi. 3.—Short neat cup, fine flame; constant and fine.

Endymion, By. 1.—Short cup, lilac flame, good.

Fanny Kemble, By. 2.—Fine large cup, purple flame on a pure white ground. Mr. Groom gave £75 for this not many years since.

Garibaldi, Bi. 2.—Short stout cup, fine base, clear lemon-yellow; fine.

General Havelock, Bi. 3.—Large, fine form, rich red feather finely laid on.

George Lightbody, Bi. 2.—This flower cannot be excelled in any quality required in a tulip; it is rather large, the shape that of Catafalque, very stout, with broad petals, in purity perfect; the yellow is a shade deeper than the best state of *Polyphemus*, and the black feather is equal or superior to that of *Lueifer* or *Paragon*.

Glory of Stapleford, R. 2.—Short cup, stout broad petals; narrow flame of soft rose, and rich cherry-red feather; a most beautiful flower.

Harriet Hepworth, R. 2.—A fine, stout, heavily-feathered flower, with every good quality.

Horatio, Bi. 4.—Fine form and strong stem, quite pure; deep rich yellow, dark bronze and crimson flame and feather; the pencilling precise and brilliant.

Indispensable, By. 2.—A wide goblet-shaped flower, standing finely on a stout pillar, the form, carriage, and substance grand; nearly black flame and feather of the very finest proportions.

Inkerman, By. 2.—Brilliant white, with broad jet black feather, fine form and substance. Good for a twelve, or even six.

Iris, By. 4.—Form good, petals broad and stout, broad beam and narrow feather of intense purple.

Jason, Bi. 1.—Large, grand form, beautiful feather; early.

John Bright, Bi. 4.—An enormous flower borne on a stout pillar; splendid crimson flame and feather.

John Linton, By. 4.—A bold strong flower, perfect in shape and purity, never known to quarter; medium black feather.

John Thornley, By. 3.—Large, finely turned at the base, from whence the cup contracts upwards; the petals of great breadth and quite thick, perfectly pure and transparent white; the feather finely drawn and shining black.

Kossuth, Bi. 2.—Shape perfect and fine substance, pure circular base of deep yellow, broad beam of red from which proceed rays to the margin. Scarcely a show flower, but in the bed admirable.

Leopora, R. 4.—A fine stout flower, with deep carmine flame and feather; a pleasing flower for the uninitiated and a gem for the faney.

Lucifer, Bi. 2.—In the description of George Lightbody we speak of that flower having a finer feather than Lucifer; nevertheless, Lucifer is one of the best bizarre varieties in the collection, and when at its best the contrast between its jet-black pencilling and its clear gold ground is delightful.

Mahomet, By. 3.—Shape, substance, and purity perfect; sharp narrow feather of black and broad flame of darkest violet.

Mary Headly, R. 3.—Fine form, beautiful flame, surpassing Cameux de Craix.

Mary Thornley, R. 2.—Extraordinary fine form, the petals broad and stout, finely rounded at the base, and curving inward at the summit; purity unsurpassable; the marking is a medium feather of bright carmine on a brilliant flame of the same colour.

Neptune, Bi. 4.—Petals rather loose at the base, but stout, pure, and pleasing; broad purple beam.

Nestor, Bi. 3.—Very large, petals rather pointed, pure; brown feather and reddish brown flame.

Nonpareil, Bi. 3.—A fine cup, very stout, and quite pure; deep yellow with dark brown feather. In the way of Polyphemus, but of course better.

Oscar, Bi. 2.—Large, perfect shape, pure; deep yellow with narrow red feather.

Othello, By. 2.—Extra fine black flame and feather; first-rate.

Pallas, R. 4.—Very large, fine shape; broad flame of carmine, narrow feather of purplish rose.

Pandanus, Bi. 1.—Short cup, pleasing narrow feather.

Paragon, Bi. 3.—Rather below medium size, cup finely turned at the base, in every quality good; deep yellow, with narrow feather of lustrous black. A truly splendid flower.

Princess of Wales, R. 2.—Short cup, fine base, petals thick and broad, marking a brilliant rosy feather on a snow-white ground; a flower of peerless beauty.

Proserpine, By. 2.—Fine form, richly feathered; first-rate.

Regalia, R. 4.—Fine short cup, the marking a flame of rosy scarlet interspersed with narrow stripes of blood colour.

Regina, R. 1.—Another of the choice gems of this collection; the form is most beautiful, and the whiteness pure as new-fallen snow; the marking is a brilliant flame.

Richard Cobden, Bi. 3.—Medium size, clear yellow ground, dark flame and feather; superb pencilling and perfect purity.

Richard Headly, Bi. 2.—One of the most perfect cups ever seen, and of course quite pure; ground rich orange-yellow, the marking a finely-pencilled black feather. This well deserves its name; for as a type of perfect form and marking, it will carry Mr. Headly's name to a far posterity of tulip-growers.

Rosalind, R. 3.—Beautiful form and exquisitely pure; feather and flame of deep scarlet.

Rose Abigail, R. 2.—Superbly flamed, quite pure, and a pleasing flower.

Rose Adeline, R. 3.—Small goblet-shaped cup, stout petals; narrow feather and broad flame of vivid scarlet.

Rose Exquisite, R. 1.—A very pleasing feathered flower.

Rose Incomparable, R. 2.—First-rate in form and substance, medium size, pure, and finely finished; flame and feather of dark carmine. Surpasses the very best Triomphe Royal or Heroine.

Rozana, R. 4.—Fine form, stout tall stem, colours curious and beautiful, varying from richest rose to intense scarlet; the feather and flame equally proportioned and quite precise. One of the most *recherché* gems of the collection.

Sappho, R. 4.—Large, perfect shape, extra stout pillar; broad scarlet feather; anthers large; the flower perfectly pure, and exceedingly showy.

Sarah Headly, R. 3.—Short cup expanding to a beautiful goblet form, great breadth and substance of petal, never quartering; the marking is a deep solid crimson feather on a pure white ground. It is equally remarkable for its symmetrical form and colouring as for its constancy; it is never flamed. It is quite distinct from Circe, though like it.

Semiramis, R. 3.—A grand heavily-flamed flower; good for a six.

Shirley Hibberd, By. 2.—Large and stout, the cup nobly turned, rose purple flame, and dark purple feather on a ground of the purest white. Mr. Headly has conferred a compliment which I shall esteem all my days in naming after me this exquisitely perfect flower, which Mr. Lightbody considers the very best of its class. It is in the way of Adonia, but larger; the white more sparkling, and the flame and feather heavier and more elaborately pencilled.

Sir Alexander Cockburn.—Large bold cup, dark blackish maroon feather; a splendid flower. I much regret I have no note of its class and height. It took the premier place at the last Cambridge Show.

Sir Charles Napier, By. 4.—Large, fine form, broad feather of lustrous black. Not pure when it first opens, but becomes quite pure after a few days.

Sir Colin Campbell, Bi. 2.—Large, fine form, broadest at the base, perfectly feathered in the style of Everard, without interior marking. Long-lasting and sure to please. Fit for the choicest twenty-four.

Siren, R. 2.—First-rate in form and substance, broad at the base, showing a finely turned shoulder; narrow and precise feather of light carmine. One of the noblest tulips known.

Sir John Lawrence, By. 3.—A charmingly turned cup of medium size, the feather broad, intense black and glossy as if varnished. Refined and highly finished.

Sir William Peel, Bi. 4.—Tremendously large, extra stout, on a stem like a walking-stick, the form perfect; yellow, with broad dark brown feather and beam, and rays of crimson and brown running into the feather. A remarkable flower in every way.

Statira, R. 4.—Very large and stout, rather long, pure; broad feather of rich carmine; a striking flower.

Thomas Allestree, Bi. 1.—Rather small, but neat and good; the marking a decided flame; rather late.

Titian, Bi. 3.—Finely flamed and fiery red; surpassing Strong's Titian.

William Tell, Bi. 1.—Short cup, with fine shoulder and stout petal; rich black flame and feather.

Those of our readers who have long been familiar with Mr. Headly's tulips will be rejoiced to hear that the infamous practice of poisoning, pursued by some unknown hand, has ceased. Mr. Headly's losses for many years in succession, through the devilish spite of an unknown enemy, would have driven any man of ordinary temperament out of floriculture in despair. The results of the poisoning were not only losses of plants of all kinds in immense quantities, but the utter extinction of several of the finest varieties of tulips broken at Stapleford. S. H.

SCUFFLE-HOE.

Mr. George P. Allen, of Woodbury, Connecticut, is the inventor and patentee of this little implement. It is a scuffle-hoe, consisting of a thin steel blade, with two cutting edges, which consist of a series of acute teeth, sharpened from the under side. Held naturally, by a man standing erect, the blade lies perfectly flat upon the ground, and raising or lowering the handle gives it a tendency to enter, if shoved or drawn. The common straight-bladed scuffle-hoe, though sharp, often meets with considerable resistance from roots of grass and weeds, and frequently slips over them; even hard lumps of soil obstruct its movement. This hoe readily passes through the clods, and cuts any kind of roots with ease. It is especially adapted to hoeing among garden vegetables, carrots, onions, and roots in the field.—*American Agriculturist*.

AN INTERNATIONAL ROSE SHOW.

Would not all rose-lovers like to know where Gulistan is? Alas! they will answer us, Gulistan is no more. Saadi's sweet country of rose-gardens and nightingales is that which Italy was—a "geographical expression!" As easy to find the bones of Majnun and Lailce, or the cup of gold and amethysts buried with Hafiz, or the flask of solid amber full of the water of Heaven which King Giamshid bought of the Peri, as to discover Gulistan. The nearest thing to it may be Cashmere, where, for half the year at least, the shawl-goats graze among thickets of pink roses, where the gazelles munch their hlossoms and huds, and the bears feed upon the scarlet berries of the great clusters, when the petals have fallen and made the grass like the Lake of Srinugger with its red lilies, all green and crimson. There, truly, in the rosy season—as the Cashmere singers say—the breeze is "as tho' the gate of God were set ajar a little;" and when travellers are entering into the beautiful valley, they know it by the odour and the far-off flush of colour on the uplands—as if the sunset light upon the snow had come down in a rosy avalanche—and by the troops of girls laden with rose-blossoms for the makers of attar. But even Cashmere is not what Gulistan would have been for those who serve and love the Queen of Flowers with the passion due to her perfect grace and beauty. It was in Gulistan that the first rose appeared, as the poet Jami has explained to rose-lovers, because the flowers demanded a sovereign from Allah, and the lotus would not keep awake o' nights. She was white at first, and the thorns were given to guard her; but the nightingales fell into such raptures of passion about her charms, and pressed their lovesick and musical hearts so recklessly against the rose-thorns, that their blood turned half the Bostan roses crimson, as far into the blossoms as it could trickle. Are not all rose-petals, as the poet justly says, white at the extremity, where the nightingales' hood could not reach? If in this hard age we disbelieve Jami Lesish, we cannot forget Gulistan is the place where so many roses were grown that it was a five days' camel ride through the great garden. Thence came the attar of the Shah, and there the fresh leaves were daily plucked for the bed of his Sultana, who could not sleep if the rose-leaves were too much crumpled. In Gulistan they found out how to make "rose-wine" with honey, apricots, new grapes, and the middle leaves of rose-huds—liquor which would render a king merciful or a sick man sleep amid any pain; and in Gulistan they all knew what were those "five secrets of Allah," which the five petals of the first rose signified. Well, we don't remember exactly where this pleasant land was, or is, but we can tell the faithful votaries of roses into whose souls the nightingales of Saadi and Hafiz have migrated, where there is still a Gulistan even in this prosaic and practical age. Not far off either, which makes it better than that Persian paradise of nightingales and blossoms; for our Gulistan of to-day is in the department of the Seine et Marne, at Brie Comte Rohert—return tickets from Dover or Folkestone at one fare and a half. There they grow roses quite in the ancient, splendid, wholesome, odoriferous, and overwhelming style of the "gardens of Gul;" two million bushes are planted round this rosy French oasis; rivers of rose-water are manufactured from its harvest of hlossoms; zephyrs, breezes, hurricanes, tornados, nay, cyclones of delicious roseate aroma hourly sweep the distinguished nostrils of the fortunate Brie-Comte-Rohertois; and here, this very next month, they are going to hold a rose show, a gathering of the kings and queens of the flower world, a Field of the Cloth of Crimson and Gold among the thousand aspirants to the first place in the glorious descendants of the white rose of Gulistan. The tidings ought to set all rose-lovers on the *qui vive*, disturb the newest and proudest flowers of our English gardens, to render Celine herself paler, and to make the white imperial cheek of Juno blush deeper with pride and ambition.

Brie Comte Robert does not do things by halves! Brie Comte Robert believes in roses heart and soul; and when the rivalry is between two million plants, it is useless going to the tournament of delicious fragrance and dazzling hues with anything save splendid and gently specimens. Last year Brie Comte Robert exhibited to all the *rosicristes* who attended no fewer than seventy-eight thousand examples and varieties of hlossom. What glorious forms there must have been! what pure colours! what celestial perfection of those odours, the inner essence of which—"the attar of the attar"—the Persian poets call the "breath of the angels!" How well might the true votary of the rose, the lineal descendant by Mr. Darwin's pedigrees of the Bulbul of Bosrah, have sighed his soul out

against the thorn of three or four of these blossom queens, and "died of a rose, in aromatic pain." If our rosarians have faith in their favourites, let them throw down the glove—a fox-glove, say—to the champions of the assembled loveliness of Franco, and challenge them to produce the Crown of Beauty. Nay, why should there not be next year, if not this season, a prodigious concourse and competition of all the roses of all the world at Brie Comte Robert, or somewhere else? To that array might come, not merely the named flowers of this or that great show—the "St. Joseph," the "Souvenir d'un Ami," and the baptised and Christian blossoms—but their beautiful pagan and heathen sisters, the infidel blooms, the heretic buds, the Turk moss-roses from the Caucasus and Circassia, tea-scented China roses from their own hill-sides, the Bourbon rose from the palm thickets of Mauritius, and the true damask, which grows wild at Damascus among the oleanders and white lilies of the swift, cold Abana. Ay, and that compound householder of roses should be there too—the *rosa arvensis*, the wild dog-rose, which, like the poor, has no state nor show, but gold in its heart and a true gift of the fragrance of faith and love.

The idea might well seize upon the enthusiast in floriculture with a fascination like that of the roses which Catharine of Medicis drugged for her deliciously enchanted victims. The international and universal show might include representatives from the gardens and green places of the whole world, with prizes worthy of the wonderful loveliness of the Queen Flower, and an exposition of the minor blossoms to do becoming and loyal honour to the occasion. The fair judges might wear robes of crimson, white, rose-pink, scarlet, blood-red, sulphur, yellow, saffron, and blush colour; and they should be ladies above every suspicion of partiality, save that suggested by kindred complexion. The visitors might give the final vote by ballot with roses of the respective colours, and the grower of the elected and consecrated flower should be made a peer of the realm, or a bishop, or anything most agreeable.—*Daily Telegraph*.

DESTRUCTION OF BRITISH BIRDS.

The author of "British Birds' Eggs and Nests Popularly Described" writes to the *Yorkshire Gazette* regarding the destruction of British birds in the following terms:—

There are several things which church-goers pray against, many people are guilty of, and nobody defends. Like these in the latter points I had fancied rock-bird shooting had been, until a correspondent of yours, with a logic and orthography equally remarkable, lifted up his voice in its favour. I had always thought it fit to be characterized—stigmatized, if you like to print it so—as cold-blooded barbarity in the act, flavoured with wanton cruelty in the accompaniments. Perhaps I am wrong; and there is a difference between sparrows and willocks in the sight of One who, we are told, notices the fall of the former. Not unlike to rock-bird shooting is rook shooting in many respects, almost all those involving cruelty included. Surely it is defended; and the defence in both its parts is enough to amaze a man in his senses. But my object now is not to expose a fallacy so much as to point out a folly. This is the time of year for slaughtering young rooks in the sight of their parents, and for shooting the old ones if they can be come upon on the fields. One such, which was shot a few days since, I wish to make mention of. My informant, a respectable farmer, had noticed it following his plough very closely, and not idly. Unluckily, as he turned his horses at the top of the field, it not only flew a few yards out of his way, but into the way of a gunner on the other side of the hedge. The poor bird was shot at, of course, and sorely wounded. Flying with difficulty across the field, it was seen by a third man, vomiting, with the sickness of death upon it. Going to the place, he found it had thrown up forty-nine wire-worms, and a large number besides of the fatter white grub, such as the plough so often turns up at this season. My informant's subject of discourse had been that "the corn was sairly grubbed" in this neighbourhood; his reflection, "I think the craws ower mich shot;" and his illustration, what I have just now given an account of. As a pendant to the above, let me record that one of the ablest living English ornithologists told me a year or two since that, seeing a gamekeeper carrying a kestrel he had just shot, and being unable to convince him in any other way that it might be as well sometimes to allow a little inquiry to precede "giving the dog a bad name" and summarily "hanging him," he requested him to allow the crow of the bird, evidently well packed, to be opened. The gamekeeper assented, and the ornithologist himself took out a compact ball filling the entire cavity of the craw. On being resolved into its component parts by a little gentle manipulation, the ball was found to consist of 119 wire-worms, and no other article of food whatever. So much for the "mischievous" done by the rook and the kestrel.

May I add, as a hint to any who, in the coming fruit season, may be desirous to save their strawberries and currants, and yet spare the blackbirds and thrushes, that many years ago I knew a large garden in Essex, situate almost close under the walls of a park in which blackbirds and thrushes lived utterly unmolested, and consequently greatly abounded, kept utterly free from these plunderers throughout the fruit season. The "dodge" was a very simple one. A cat, which had two or three kittens, about one-third grown, belonging to her, was provided with a box to live in, placed in the garden, a collar round her neck with a short light chain attached, and terminating in a small ring. The ring traversed on a long stout wire fixed between low posts some thirty or forty yards apart, and so the oat, when disposed for exercise, padded herself a path along the wire, and the kittens frisked about all over the garden. All of them looked as happy and sleek and jolly as possible, but the blackbirds and the thrushes unanimously voted the fruit in that garden "sour." They never came near it.

THIS IS AN AGE OF WONDERS. It is reported that a Mr. Firminger has discovered a process of growing peaches, plums, and cherries without stones. He splits a branch and removes the pith; the split halves are then brought together and bandaged until they unite. The next step in the process is to inarch this pithless branch on a suitable stock. When the inarched branch has made a season's growth, a portion of it is selected and denuded of pith, and this is inarched as before. After successive repetitions of this process, the fruits become stoneless; but whether they contain more pulp, or have any better flavour than fruits containing stones, we are not informed. Another story is current of a gardener in Ghent, who gives to any fruit the flavour he desires by puncturing it while growing, and then immersing it in a liquid flavoured for the purpose. We should feel that our duty was but half discharged, in placing these things on record, if we did not add that we regard them as absurd inventions, calculated at the best only to provoke a smile at the expense of all who believe in them.

Calendar.

WORK FOR WEEK COMMENCING JUNE 22.

Kitchen Garden and Frame Grounds.

BROCCOLI from late sowings to be pricked out, and young plants in a forward state to be planted out, where they are to remain in soil deeply dug and liberally manured.

BAUSSELS SPROUTS to be planted out as fast as possible. Previous to the late rains we got out a large quantity in rows, between potatoes, and they are now looking remarkably well. The soil must be in good condition for these, for if they are not fine, they are scarcely worth having.

COLLARDS should be planted in quantity, as ground can be obtained for them. Plant them rather thick.

CELERY to be planted at every opportunity. Deep trenches may be used now, but in another few weeks it will be advisable to make the trenches shallow, because the late planted crops will have to stand out the winter. Any remaining in seed-pans or boxes may now be pricked out in beds in the open ground.

SPINACH.—If requisite to sow now, give the preference to the prickly seeded variety, which is used for winter spinach, as it is less likely to bolt in case of hot dry weather.

TOMATOES to be trained and stopped. If not frequently stopped a good crop cannot be expected.

ROOT CROPS, such as parsnip and beet, require now a final thinning; there is no gain from crowded beds. Potatoes to be frequently hoed between; we have no great faith in the practice of moulding up the rows, but it is everywhere practised, and is evidently not seriously detrimental to the crop. If children can be employed to pick off the blossoms, the weight of the crop will be increased, but the difference will scarcely pay for any other kind of labour.

Sow, for succession, Mazagan beans, York, Rosette Colewort, and Collard cabbage, cucumbers (Highland Mary is one of the best to start now), endive, French beans, onions, parsley, peas, turnip radish.

Flower Garden.

RHODODENDRONS, KALMIAS, AND ANDROMEDAS may now be layered for increase; it is the simplest and surest method of propagation, though slow; nevertheless they are always better on their own roots than grafted, and though many kinds sow themselves in plenty, and produce thickets of seedlings if allowed, there is no dependence to be placed on them for character when at last they come into bloom. Old beds of American plants may be benefited now by top-dressings of cow-dung quite rotten. Recently formed beds should not have it; nevertheless a mulching of some kind, especially amongst Kalmias, will be beneficial. Where moss is plentiful, there is nothing better to strew three or four inches thick over the whole of the soil; it soon sinks to a close peaty layer, and preserves a moist condition of the roots.

CARNATIONS AND PICOTEES have been terribly afflicted with fly of late, but the recent rains have pretty well cleansed them. The buds must be thinned, and all other needful preparations made to prepare for a good bloom.

DAHLIAS must be safely staked, or the first gale will lay them low.

HOLLYHOCKS must be securely staked.

ROSES are looking well since the cool rains, and all lights and maggots have disappeared. Heavy rains do more for roses in a few hours than artificial aids can do in a whole season. Look over the stock of briars intended for budding, and cut away all superfluous shoots to the base, and slightly shorten those that are so placed as to be suitable for budding. By the time the general budding season arrives the shoots thus shortened will be in full growth again, and will take the buds more readily. In some places, however, thousands of briars have been budded already, and if the work can be well done, the early doing it is a great advantage, because of the growth that can be got during the present season. Therefore, we say, make ready to work the strongest briars at once, and as soon as plump buds can be obtained of the choicest varieties. Buds that remain dormant till the next spring do not generally make such good plants as buds that start away soon after being entered, and make ripe hard shoots before winter. We have found that when the shoots from the buds of the season were very sappy, a gentle lift of the stock by means of a four-tined fork, early in October, gave a check that hastened the ripening, and prevented loss in winter. We mention this now because some propagators prefer dormant buds, because of the risk in winter, whereas pushing buds can be used with equal safety if means are resorted to to check the growth in time. Another matter worthy of mention is that the wild wood should not be cut away severely before entering the buds, as a loss of it checks the flow of sap, and defers the complete junction of the two barks.

BULBS in pots, that flowered in spring and have now finished their growth, will be better worth keeping if the pots are placed on a shelf in a hot lean-to. This is the way we are now dealing with our stock; the object is to roast them before shaking them out of the pots. Cape bulbs require much the same sort of treatment, but care must be taken to keep them growing a reasonable time after flowering, till, in fact, they have "made themselves" for the next season. It is because we do not ripen bulbs sufficiently that so few are of any value after having once flowered.

CHRYSANTHEMUMS to have plenty of water, and to be assiduously trained. Cuttings struck now, and carefully grown, will make very pretty small specimen plants.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Apple-trees are now recovering from the devastation of caterpillar, and need a careful inspection, pruning-knife in hand, to remove spurs and branches that have perished through loss of sap when they were covered with vermin during the drought. Tie in espaliers at once, before the shoots get set in a bent position. Use the engine smartly to wall trees and bushes; nail in the wood to be kept on wall trees, and remove, but not too much at a time, all superfluous wood. We must again object to the too common practice of laying in all the wood that can be got, till the walls are literally felted with young shoots; one-half of these can never ripen so as to be of any use, and the keeping of an excessive amount of spray defers its object—the general remark that "we don't know what we may want" being founded in a misapprehension of the subject altogether. We have seen walls lately covered with at least three layers of shoots one over the other, and we have no longer been in a mystery that, though the trees grew well, they

produced but little fruit. Wall trees trimmed up now will have time to ripen their wood; if neglected much longer, it will be too late to do justice to them.

ORCHARD HOUSE TREES require very little attention now beyond abundant watering, and the use of strong liquid manure. No more pinching to be done. Shoots badly placed may be removed now without fear of causing the buds at the base to break.

AMERICAN BLIGHT is now making its appearance on apple trees. We find the aphid wash a cheap and effectual settler for it. A hard-brush plied upon the parts affected, without any medicament, has a very decisive effect. It is not safe to use brine now, but when the leaves are off brine is one of the best of purifiers for apple-trees.

PINCHING must be practised with assiduity in fruit gardens where pyramids and bushes are grown. There is one thing to be said about pinching, namely, that once commenced it must be continued, for if neglected the shorter growth, clothed with spurs, is soon buried under a forest of spray, which breaks out on all sides, and very soon alters the character of the trees entirely.

Greenhouse and Conservatory.

CONSERVATORY plants require abundance of water and a free circulation of air amongst them. Climbers must never be neglected, or the growth will become so confused that to restore anything like order much of it must be cut away. Moisten all walls, borders, and stone-work the last thing in the evening, to create a humid atmosphere.

BEAUCARNEAS and their allies are generally very badly treated, hence the rarity of good specimens. One of the greatest secrets of success is to give them abundance of water at this season; it is scarcely possible to overdo it.

FUCHSIAS should be propagated now in quantity. Specimen plants will require abundance of water, and once a week liquid manure. Fuchsias in the open ground are generally disfigured with a superabundance of sticks, whereas in a good turfy soil, with a moderate amount of rotten dung, they ought to need but little artificial support, and a certain easy drooping habit is proper to their character. Most of the light fuchsias require to be well shaded, or the points of the calyx acquire a green tinge.

AZALEAS and CAMELIAS, if still under glass, must have air night and day, and the floors kept damp. Use the syringe regularly till the flower-buds show at the points of the shoots, and then discontinue the use of the syringe.

SOFT-WOODED PLANTS, such as Cinerarias, herbaceous Calceolarias, Chinese Primulas, Pansies, Pyrethrums, &c., should be raised from seed now in quantity. If Primulas were sown in April for early bloom, it will be as well to sow again for a successional batch. Remember that to grow bad seed is just as much trouble as the best, so that the question of cost of seed should not be considered too closely. Procure the best that can be had from houses known to be above the shabby practice of mixing or misdescribing, and grow them in a good compost from the first. Soft-wooded plants rarely do any good if grown slowly; they need abundant nourishment, and if kept stout and strong rarely suffer from vermin. It is the bad practice of starving seedlings in the seed pans that creates the principal trouble of getting them clean afterwards.

HARD-WOODED PLANTS that have flowered will require to be pruned in and set in a shady place to rest awhile, and repotted if needful when they have started into a new growth.

CINERARIAS are now very forward in the seed-bed, and the largest must be potted off and put in a frame. A bed of spent hops answers admirably for them.

Stove and Orchid House.

ACHIMENES need help from liquid manure to prolong their beauty and develop the foliage and flowers fully. The best contrivances now in use for displaying them are the open wire baskets humorously designated "crinoline pots;" in these they grow to perfection, probably because of the access of air to the roots.

IXORAS.—These cannot be kept in order as specimens without careful treatment. As soon as the bloom is nearly past cut them back rather sharply, and put them in a good heat to start again. When freely in growth, shift any that require it; or if not, remove a portion of the soil and replace it with fresh.

Forcing Pit.

VINES that have ripened their fruit must be carefully brought into a resting condition by gradually withholding water, and exposing the wood to the weather night and day, except during rain. Crops ripening to have the help of fire-heat in case of a prolonged term of cloudy or cold weather, as any delay in ripening will bring on mildew. Where the grapes are just stoning, attention should be paid for the last time to thinning and tying in, but do not cut away every apparently superfluous shoot; very often a few random growths help to sustain the vigour of the vine, and are in fact the signs of vigour; but of course these should not overlap the old wood, or shade the leaves that have bunches to take care of. Where ripe grapes are to hang, keep the house dry; and, to prevent red spider, paint some tiles with sulphur vivum, and lay about in the full sun.

FINES must have air pretty freely, and abundance of water both to the roots of the plants and to all parts of the pit, to promote a humid atmosphere.

STRAWBERRIES making runners freely are best rooted at once into the fruiting pots if intended for forcing. It will be found that they soon fill the pots with roots and form good crowns; and there is a great saving of labour. Let the soil be sound loam, with a liberal allowance of manure; and in filling the pots, press it in as firm as possible.

Correspondence.

MANURE FOR GRASS PLOTS.—Having read your article on the "Restoration of Grass Plots," in your number of the 8th instant, I think it may interest your correspondent J. V. to know that an article which has lately made its appearance is highly adapted for the object he wishes to attain. In the early part of the year I bought a packet, which cost me one shilling, of the "Paxton Manure for Gardens" and grass-lawns, and mixing it with a small quantity of fine earth, in order to test its value, I wrote my name with it on my lawn at the back of my house. In less than three weeks I could distinctly read my name in grass, which was not only of a darker green, but considerably higher than the rest of the lawn. I have since used the same manure for cucumbers with great success. I enclose my card.

CONSTANT READER.

CULTIVATION OF CERTAIN BRITISH FERNS.

Aspleniums require thorough drainage. They grow freely when planted in light loam (enriched, if need be, by the addition of well decayed leaf-mould and fine sand), with a fair quantity of broken limestone or old lime rubbish interspersed.

Athyriums—The most important requirements of the *Lady Fern* and its numerous varieties are abundance of moisture in the growing season and partial shade. When grown in pots they should have, at the above season, abundance of pot room. Thorough drainage is of less importance. Plant in a compost of fibrous peat, loam, leaf-mould, and sand. The *Athyrium filix-femina* and its varieties are all of them deciduous; they are perfectly hardy, and make beautiful objects for the out-door fernery.

Cystopteris fragilis and varieties do well in a compost of fibrous peat and loam, with a little thoroughly decayed leaf-mould and fine sand added, and a small amount of old crumbled mortar. They are especially eligible for situations a little moist in the rockery. It is important to drain well.

Lastrea thelypteris.—This beautiful deciduous fern requires a peaty soil, continuously moist. Its delicate-looking yellowish green fronds make a charming variation from the darker green of other ferns. Does finely in a hog.

Polypodium vulgare is a fine evergreen, and the most beautiful varieties, such as *cambriacum*, *omilacrum*, and *pulcherrimum* are, perhaps, the freest growing. Plant in a compost of fibrous peat, leaf-mould, and silver-sand, taking care to give ample drainage, and to place the rhizomes on the surface of the soil, securing them there with wooden pins until the plant is well established.

Polypodium dryopteris.—Plant in a moist shady nook of the rockery, using a compost of fibrous peat, leaf-mould, and silver-sand; it is important to drain well.

Polystichum angulare.—It is a mistake to plant this in peat, as is so frequently done. No doubt it may be made to grow in peat enriched with decayed leaf-mould, but the plant's natural aliment and consequent requirement is loam—a rich loam. Silver-sand should form an element in the compost; and pieces of grit, and also small pieces of lime-rock, may with advantage be introduced; the drainage should be ample.

Scelopendrium vulgare.—Grown in the shade and given abundance of moisture, this is one of the most beautiful of evergreens. When an attempt to cultivate it has failed, it has generally been through neglect to give the plants the necessary amount of water. Most variable of all ferns, its named forms or varieties are now counted by hundreds. Plant in sandy loam, in a moist, shady, sheltered nook. Tenderer subjects may be planted in a compost of loam, fibry peat, and silver-sand. In either case a small quantity of well decayed leaf-mould may be added, and in all cases the plant is benefited by bits of limestone (or a small quantity of old crumbled mortar, or broken oyster-shells) being interspersed through the compost, the Hart's Tongue fern being a true limestone plant. Provided the drainage be perfect, too much water can hardly be given during the season of growth, though, of course, it is not well to subject the plants to a constant deluge.

Woodsias.—Stagnant water and stagnant air are alike hurtful to these beautiful little ferns; ample drainage and thorough ventilation are therefore essential conditions in cultivation. But though well drained, the soil should not be allowed to get too dry. A cool airy situation, with a moist soil, is the one in which the plants are most at home. For compost use mainly fibrous peat, with a fair amount of silver-sand, a little thoroughly decomposed leaf-mould, and a small proportion of loam. As the *Woodsias* require a cool situation, one with a northern aspect is obviously the best.

Killarney Fern (*Trichomanes radicans*).—Though it is best, as a rule, to grow the bristle fern in a close glazed case, it frequently makes most luxuriant growths without such confinement, and planted merely in a shady corner of a cool house. But a uniformly moist atmosphere is essential, and when this condition cannot be insured in the place where the fern is to be grown, then a glazed case becomes necessary. What moisture the plants receive should be in the form of exhalation; avoid casting water directly upon the fronds. It will be seen that the lovely bristle fern in cultivation is essentially a greenhouse or quasi-greenhouse species.—*Descriptive Catalogue of British Ferns*. A. Stansfield, Todmorden, Lancashire.

SCOTCH AND ENGLISH SHEEP-DOGS.

We now come to our own beautiful and beloved colley, looked up to for centuries as the most ancient strain and purest breed of sheep-dog, and from whom have doubtless sprung a variety of other most serviceable and intelligent guardians of our flocks and herds. A cross, indeed, from this most esteemed animal is perhaps better suited for general purposes than a true or thorough-bred one, as, taken from his native hills and natural habits, there is a downcast air and melancholy pervading him which apparently interferes with his exquisite sagacity; he works as it were with a weight about him; there is wanting that joyous action and light-heartedness of expression for which at home he is so famed and admired. This most interesting of all the species has been, of late years, familiarized to all of us through the inimitable pencil of Sir Edwin Landseer, who has taken every opportunity of presenting him before us, accompanied with some charming or touching sentiment, his refined appearance adding immensely to the delightful impression. The shepherds throughout Scotland, and also the north of England, take especial care to preserve unmixed with "baser matter" their breed of these valuable dogs, and a very high price is set upon them, according to their pureness and pedigree. We have seen £50 almost indignantly refused in more than one instance. Nor is this surprising when their accomplishments are considered, and the saving in labour and time thereby gained. On the Grampians it would be impossible to find a substitute for the faithful and intelligent colley, for thereabouts, in the valleys and glens, reside many shepherds, and the pastures over which their flocks are permitted to range extend for many miles in every direction; indeed, the owner has no possibility of viewing his whole flock at once, excepting collected for some particular purpose, such as for sale, or for shearing; and thus, as he can only visit them partly at a time, it becomes the duty of his dog to keep the sheep within bounds, and prevent them mixing with his neighbours', and also to drive back all intruders, a task requiring considerable discrimination, and one of no trifling labour.

Of the English sheep-dog there are two or three varieties, although in many respects closely resembling each other, and doubtless they are all

newly related. The tailless species is, we believe, a Yorkshire dog, and, strange as it may appear, this deficiency in nature's fair proportions has become quite hereditary amongst a certain strain, although probably it had an accidental origin; for I have repeatedly seen a litter of puppies one-half of whom possessed tails, whilst the other half had none. This sort of dog is a strong, wiry-coated, generally curly, and particularly muscular animal, especially about the loins and hind-quarters; he is often of a savage disposition, and given to fighting; he is mostly seen with drovers, and is used chiefly for cattle; he is extremely courageous, and will face, without flinching, the most desperate beast; being generally what is termed hard-mouthed, his lower fangs are frequently filed down to prevent his injuring the herd whilst at work; he is wonderfully active, full of intelligence, and delights in his calling, to which may be added that he is true and faithful to his master. The dog most familiar to all of us, and seen daily on our farms and downs patiently tending his gentle care, is a very handsome and picturesque animal. He is ordinarily of a blue gray colour, with white breast and patch on the face, and either curly or flowing coat. Of a most enduring and amiable nature, he devotes himself entirely to his duties, is seldom or ever seen astray, and follows the heel of the shepherd or reposes on his coat with that serious air and undeviating attention which prove how much at heart he has the welfare of the flock, and the interests of those whose will he obeys. There are many very entertaining stories illustrative of his intelligence and faithful disposition; but, for fear I might repeat an oft-told tale, I will merely relate one or two incidents that have come under my own observation.

Having occasion to call on a friend a few miles from Winchester, I descended at that station, and proceeded on foot across the country; during my walk I had to pass through a very large field, one half of which I observed was seed-crop, the other being pasture, on which were feeding some hundred or more of Southdowns. My attention was shortly attracted to the faithful dog, who was walking, with sentinel-like punctuality, up and down the boundary line of the two crops, close to which some of his trust were browsing. Upon the slightest attempt of any of them to infringe on the seed, he immediately drove them back; but the extent of his beat being very long, he was sometimes sorely put to it, and had to hurry backwards and forwards in rather a laughable manner. Collecting his energy, he finished by driving the whole flock to the extremity of the pasture; then, satisfied with the altered position of affairs, he returned to the boundary line, and lay down with the assurance that they must now feed up to him. Four hours afterwards, on recrossing the field, all was as it should be, and the guardian of the limited liability still reposed undisturbed *in media res*. I was greatly gratified at such an admirable display of canine sagacity.

The following is even more extraordinary. Mr. Scott, a farmer near Bishopstoke, in Hampshire, possesses a remarkably intelligent sheep-dog of the English breed. Not long since he accompanied him to Appleshaw Fair, where he purchased a lot of sheep, upwards of two hundred and fifty. At night, in bringing them home, they were turned into some meadow land with several other droves; they consequently soon all became mixed together. The next morning, without making a single mistake, the dog picked out the whole of his master's sheep from amongst the others, almost unaided, and although he had been so short a time acquainted with them, after which he drove them to their destination single-handed. This feat Mr. Scott may well be proud of repeating, as it has seldom or ever been equalled, never surpassed, for brilliant intelligence and canine observation.

There are certain peculiarities of character belonging to the sheep-dog well worthy of note. He is a remarkably small eater, and is the least greedy of all the entire race—in fact, it is quite astonishing how many hours he will remain true to his post without indulging his appetite; he apparently suffers but little from hunger or thirst. He is of a pensive, melancholy disposition, and rarely condescends to join in a romp, or enjoy that playful dalliance which belongs to other animals. At the same time his affections are true and unalterable to his master, and his faithfulness under the most trying circumstances is staunch even to death; and if we should seek in the canine family for talents and qualities especially human, our convictions unhesitatingly point towards the sheep-dog.—*Land and Water.*

THE PLANTING OF COUNTRY CHURCHYARDS.

As great and well-deserved attention is now being paid to these sacred places, by neatly enclosing and beautifying them with ornamental planting, I beg a little space in your excellent paper for a few remarks on the shrubs and trees most suitable for such a sacred purpose. Church decorations and restorations are often beyond the means of a rural population, but the planting and keeping of our old churchyards can always be effected where there are willing hands and hearts. If those who wish to show regard for departed friends or relations would direct their attention to the planting and adorning of the graves where their bodies repose, instead of disfiguring the walls of our sacred fances with marble tablets and unmeaning busts, which can interest none but those who put them there, and cause disinterested admirers of our fine old churches to view them with regret and disgust, it would be much better.

In adorning these sacred resting places of our departed friends we are rather opposed to flowers, and would rather see the old sepulchral yew, whose gloomy foliage, as a fitting emblem in such a spot, has stood the test of centuries. But to make our plan and purpose clear it is necessary to draw a picture. There stands the sacred edifice surrounded with its graves and grave monuments levelled with the well kept grass. The venerable pile runs east and west; the western door opens into the centre of the churchyard, so that a wall running north and south forms the grand promenade. The north entrance is therefore the spot from which the best effect can be produced, be the other paths as they may. In laying out the ground we would make a gravel walk wide enough for three persons to walk comfortably abreast upon, and running north and south parallel with the edifice. This should be as it were the midrib, and take in the church and its surroundings on one side. The margin of the ground only should be planted with large growing trees, avoiding that egregious blunder we see almost everywhere of planting tall-growing and wide-spreading trees near buildings which in time they must bury beneath their shade. Two kinds of plants should decorate the interior of the ground—bushes or tufts and ornamental shrubs. Next to the sacred yew, we should be careful to find a conspicuous place for the Deodand, or "Tree of God," as a tree well suited for the decoration of consecrated ground. Let these be planted at all the extreme points near the walls of the churchyard, at not less than a chain length apart. Although the latter is a

large growing tree, its beautiful drooping habit and evergreen hue will make it ever a pleasing ornament to a churchyard. The cedar of Lebanon is another tree equally, if not more, deserving than the Deodora of a prominent place. Its gloomy grandeur and venerable appearance when old give it a more awe-inspiring aspect than either of the former, and we should plant, or rather scatter, two or three in open spaces. In planting churchyards, we should avoid all conformity to wood or even shrubby planting, for although the tombs should be shaded like a good picture, still the "summer sun should shine sweetly on the graves."

Then comes the yew, and when we speak of yews we mean the English yew, and not the garden variety, for there is a great deal in a name. In the days when bows and arrows were used as weapons of war they were made of yew; hence the yew-tree was a material of war. The triumphant entry into the Holy City was celebrated annually on Palm Sunday by the distribution of small twigs of the yew and willow; and the honoured dead were borne through the lych gate, and under the churchyard yew-trees, to their last resting place. The yew, therefore, has important claims to our regard, for it gave the palm to gladness, a brand to warfare, and a canopy to death. It is extremely suitable for such decoration, being a tree of evergreen habit, long lived, and hardy in the highest degree, bearing the most inclement weather without flinching. It will stand more ill usage than any other tree we know, and may be pruned, clipped, and mutilated without bounds or discrimination with impunity. Next to the cedars the ground should be well studded with English yew-trees. The tree commonly called the Irish yew should be especially excluded, being far too stiff and club-shaped for so sacred a purpose.

Next comes the juniper family (not Cypress) of scriptural interest, as giving shelter to Elijah in the wilderness of Beersheba. These will grow in any soil or any situation, but they prefer a sandy loam. They can be had of all sizes from a mere dot to a small flame-shaped tree, and the creeping and dwarf or bushy kinds are invaluable for covering the ground like a thick carpet.

There is another valuable plant that might be used for the same purpose, or even for walls, namely, the Cotoneaster. It will hang over banks gracefully, and its blue and golden associates, the "Periwinkle" and "St. John's Wort," may be used for the same purpose for the sake of variety.

Tufts of box may dot the ground, and this being a very slow growing plant, and unobscure, might occupy waste places near the eye. Some ornamental features should be introduced, and we know of nothing better and more suitable than the double flowered English gorse or whin, and the rose family. The gorse to be scattered in small groups, so as to produce in its season gold amongst the green. When this plant is not in flower it is always green and neat, and wears no varnish on its foliage like the holly. It is, therefore, easily kept in harmony with the small leaves of the cedar, juniper, and the yew. Also a few deciduous trees might with propriety be introduced at discretion, as space would admit, such as the weeping elm (being by far the most appropriate); and we should plant grafted elms between the cedars on the margin, as it is a time-honoured practice to have these tall elms, and even the weeping willow, in churchyards. The weeping willows are handsome and appropriate through the year; the Kilmarnock variety is the best.

The Ayrshire rose will be a great addition, and will be found useful to run up against walls to any height, or to cover any eyesore. It is a climbing shrub of rapid growth. Other rambling roses on stems, never to be cut back till they become almost as large as haycocks, may be planted here and there in open spots. The rose, a universal favourite, harmonises and blends with all other shades of colour, and the ground strewn with rose leaves, while some blossoms are still perfect and others in bud, will be well suited to the place and its associations, so as to bear us harmlessly through against excess of love in recommending the introduction of this queen of flowers amongst the abodes of the departed.

ALEXANDER BARCLAY, in the "Teesdale Mercury."

Replies to Queries.

W. J. B. Spoor.—A pansy sent between blotting paper in a letter at this time of year is not a pansy when it comes into our hands. If it came fresh we could not name it; we make it a rule never to try to name florists' flowers. Judging by the outline of the smashed and dessicated flower, we should consider it top-heavy and second-rate.

Stocks for Roses.—C. H. Bentley.—As you live near a great smoky town, you have no business with stocks of any kind, for the best roses for you are those on their own roots. But if you must have worked roses, like many other people who love delusions, give the preference to the Manetti over the brier, and to the Maiden's Blush over all other stocks. The last named is not much known or appreciated, but it is a good stock for gardens near towns. If urban amateurs would give the same attention to the practice of striking cuttings and eyes as they do to budding on the brier, they would have roses in reality; but as they for the most part prefer bad roses to good ones, the brier is generally in high flavour amongst them.

THE PLEASURE-GARDEN.

A fresher, brighter spot of earth, wherever you may travel,
Is seldom, very seldom, I can tell you, to be seen.
Well kept, well swept and tended are its paths of tawny gravel,
And velvet is the simile that answers to its green.

I fancy of a garden that the "lily is a lady;"
The queen, there's not a question for one moment, is the rose.
I'd like to call a nosegay from these bowers cool and shady;
But nobody's allowed to pluck the flowers, I suppose.

No weeds are here. No weeds—egad! With slightly altered meaning,
Their lack I am inclined to mourn, as, underneath this oak,
I loiter along the mossy turf, and, on my elbow leaning,
Peruse the notice, "Perseus are requested not to smoke."

My attitude recumbent is for once deserving credit,
My laziness a virtue, which it seldom is, alas!
For there's a rule most stringent—as I sanctioned here I read it—
Forbidding any visitor "to walk upon the grass."

I'll take another turn, though, for the air is getting chilly.
Ah, had I some companion, guide, philosopher, or pup,
My faithful Skye—descendant of the celebrated Billy—
But "Dogs are not admitted," so I give the notion up.

It's growing late; there'll be a storm. I'll go. What's this? By heaven!
I see the wolds, and spell them in an irreligious light,
"The gates are shut at ten." It's now a quarter to eleven;
And I'm locked in, a prisoner, this rainy summer night.—*Fun.*

The Gardener's Magazine.

SATURDAY, JUNE 29, 1867.

CLASSES FOR COLLECTIONS OF WILD FLOWERS are to be found in the schedules of provincial exhibitions almost invariably, and we may conclude therefore that they are in general favour as aids and stimulants to the study of botany by the young. There can be no doubt that in some cases they really accomplish what they are intended for, and by awakening inquiry and promoting the searching of the woods and hedgerows, they may occasionally be the means of laying the foundation of a taste for botanical studies, and of furnishing that taste with appropriate gratification at a season of life when impressions are made of a lasting nature. But it is a question which we consider by no means hard to answer, if upon the whole these competitions do not result in more harm than good; and, admitting that good does result from them, whether that good might not be obtained in some other way without any accompanying evil. Our correspondent "Cypripedium calceolus" referred to the subject in his valuable communication to last week's Magazine, and it appears to us of quite sufficient importance to merit special remark in this place; for whatever conclusions we may arrive at must bear directly on certain points requiring consideration in the preparation of a schedule.

Let us look at the facts as usually presented to us. There is a competition for so many "bunches of wild flowers," and a certain number of contributors present their gatherings. As to knowledge of botany, it scarcely needs to be said that to attach correct names to a score or so of summer wild flowers is no very satisfactory proof of mere technical acquirements, much less those higher departments of botany which are of the most practical service to the traveller, the cultivator, or the artist. But how often do we find the names correct? We speak from observation when we say that to find one collection in fifty correctly named, and with the names correctly written, is as rare as meeting with a collection that possesses one particle of interest for any except the collectors who have entered into competition. In many cases the competitors are indebted to local botanists for the names; and when these have been written and affixed to the bunches, the "study of botany" in that particular case is at an end. We admit most gladly that there are exceptions to what we are now describing as the rule, but they are few and far between; and for one mind that is awakened to a perception of analogies and relationships, and thereby led to some higher pursuit than preparing wild flowers for an exhibition, thousands are simply deluded or repulsed—deluded in the first instance by the supposition that writing names they cannot understand is equivalent to the gain of actual knowledge, and repulsed by those names and by all the apparent dryness and uselessness of scientific terminology. The system has been in operation long enough to furnish out of its own history arguments in its own defence, if it is really defensible on solid grounds; but if we ask for the names of the able botanists, or even of the persons tolerably skilled in botany, who can trace their success to the encouragement afforded by such competitions, we suspect we shall wait long for a reply. We venture to ask, indeed, if any one can tell us, not in general terms, but with the illustration of particular instances, if these competitions have ever proved of service in promoting scientific study or the love of rural pursuits, or increased attachment to the soil and to the laws and customs of our native land? To ramble through the woods, to explore the hedgerows, to notice the differences in structure, and to make comparisons of the forms and colours of wild flowers, are pursuits directly beneficial to all who engage in them, whether young or old; we might as reasonably declaim against naturalists' field clubs as object to the gathering of woodland posies, and the learning of the names of the plants composing a wilding wreath. It is the competition in such things as part of a flower show we are speaking of; and that competition we venture to pronounce of small value in an educative sense, and, if we are right in that, there is not left a single argument why these competitions should be encouraged.

Let us for a moment, in imagination, go round the tent. We see stove and greenhouse plants, pelargoniums, ericas, fruits, bouquets, all in their several degrees and styles beautiful and attractive. In due time we reach the "wild flowers," and here it seems as if the design in introducing them must be to prove that there is not a British plant in existence worth a moment's notice on account of

its beauty. We see tufts of *Lychnis*, *Lysimachia*, *Silene*, *Geranium*, *Campanula*, and less interesting and attractive subjects, grouped without taste either for contrast or harmony, frequently in a state which can scarcely be called clean, and usually as if solely intended to disgust the few who will deign to look upon them, both with the faded flowers and the names appended to them. Even the best examples are lost amid the brilliant colours and noble forms which constitute the principal features of a horticultural display; and it may be truthfully said that where this feature is carried out with the fullest spirit and integrity, it adds so little to the attractions as to be comparatively worthless, while, by the unfavourable contrasts to which the weeds, however pretty, are subjected, it is probable that many are deterred from the study of British botany who would otherwise find it to be an agreeable and healthful pursuit. We repeat that, considered in respect of the success of an exhibition, this feature is, as a rule, worthless, sometimes injurious, and in no case calculated to inspire a love for the subject in behalf of which it is instituted.

But there is another evil attending these competitions. They lead to the ruthless destruction of rare plants, to the extinction of habitats, and even to the extinction of species. The few who now know of the whereabouts of the true Maidenhair or of *Trichomanes radicans*, and some other of the loveliest British wildings, dare not divulge, through the reasonable fear of botanical Goths and Vandals, who go about hungrily seeking what they may devour in the way of a rare plant, and which, when they have devoured it, will do them no good either intellectually, morally, or materially. We noticed in Messrs. Brown's collection of hardy plants at the Manchester Exhibition (see page 254) the rare and beautiful *Maianthemum bifolium*, a plant which merits a place in every choice collection of hardy plants, and were assured by Professor Williamson that it was necessary to keep profoundly secret the name of the spot where the plant had been found growing wild; for if it became known, the whole of it would be snatched up, and the species probably be blotted out from the British Flora, and this not in the interests of science nor for the promotion of botanical studies, but to gratify an idle curiosity and the prevalent love for a rarity, no matter whether useful or not to the possessor. We occasionally meet with rare orchids, and with other plants that have not half a dozen stations in the island, in the "bunches" that for a few hours make a dingy appearance at a flower show; and the exhibitors obtain prizes on account of the rarity of their findings, and are thereby rewarded for the mischief they inflict in helping to "stamp out" some "gem of ray serene" that *Cybele* should keep for her own chaplet and for the joy of those who are her faithful followers.

It is not at all necessary to frown down the young aspirant to botanical distinctions in order to preserve the rarities of our native Flora. We should much prefer to offer substantial encouragement, accompanied with conservative teachings respecting the claims that certain plants have upon our care for their preservation. Instead of competitions at horticultural exhibitions, where they are out of place, village clubs and classes would be far preferable; and competitions might be instituted of a kind calculated to prove directly beneficial to the young without starting them on absurd errands to tear up rare plants, and make hideous bunches that are neither instructive to themselves nor gratifying to any who take notice of them. Professor Henslow gave his valuable hours and his ripe manly intellect in such a cause, and there might be found many another guiding spirit who would foster the ambition and curiosity of the young in the study of field botany; but the school-house appears to be the proper centre for the work, not the tent of the horticultural exhibition, and it is a work that needs to be pursued continuously "all the year round," not at long intervals; and moreover it needs personal supervision and direction by those who already exercise a moral influence, in preference to the verdicts of judges who are rarely competent to make awards on the ground of true merit, either in respect of the plants brought forward or the taste displayed in grouping them.

IS *LILIUM AURATUM* HARDY?—This question has been put to us on many occasions by correspondents, and it has been answered in the affirmative. Our replies have been founded on the fact of this liliun having been stored away in pots, in frames, and in beds, with only an inch or two of covering throughout the winter, without harm or loss, and from many observations of its habits and requirements we never entertained a doubt of its hardiness. But we are enabled now to bring forward a fact in corroboration of the con-

clusion. Messrs. Paul and Son, of the Cheshunt Nurseries, left out all last winter in an open border 300 bulbs, and every one of these is now growing freely and presenting fine flower-buds. Such a winter must be considered a satisfactory test, and this glorious lily may surely be added without fear to the long list of hardy plants adapted for beds and borders in gardens where there is no glass, or where it is desired to enrich the summer display with subjects requiring the least possible amount of care. Nor is this liliun particular about soil, though undoubtedly it thrives best in good lumpy peat or silky loam, such as the common brake delights in. Either of these materials is to be preferred before all composts containing stimulants.

THE SCARCITY OF VEGETABLES has been severely felt by poor people. A large quantity of the commonest kinds of vegetables has been exported from France to England, which is an unusual circumstance. A few days ago 1,400 sugar-loaf cabbages were landed at Guernsey from France; some of them weighed 14lb. They were rapidly sold at 3d. and 4d. each.

CURIOUS USES OF AN OVEN.—The *South London Press* states that an oven situate at 65, Richardson Street, Bermondsey, is used, according to the report of the inspector of nuisances, on Sundays to cook the dinners of the poor around, and on week-days to haking hair, and destroying gregarine germs before its conversion into fashionable chignons.

THE SCOTTISH PANSY SOCIETY.—This society held its twenty-third annual exhibition in the Music Hall, Edinburgh, on Friday the 14th of June, and was largely patronized by visitors. The blooms shown were excellent, both as regards the old varieties and the new sorts; and it was generally considered that the average quality rather excelled that of former years. Messrs. Downie, Laird, and Laing were as usual the chief prizetakers in the nurserymen's classes. Messrs. Dickson and Co. received a first-class certificate for some new and meritorious seedlings, named respectively Highland Mary, Robert Burns, and Fire-eater. Mr. Young, South Bridge, was awarded a certificate of merit for a final zonal geranium. Messrs. P. Lawson and Sons, Messrs. Downie, Laird, and Laing, and Messrs. Dickson and Co., sent attractive and interesting collections of plants for exhibition only.

NEW RECREATION GROUND AT DERBY.—Mr. Bass, M.P., who has been one of the Parliamentary representatives of Derby for about twenty years, has just presented a public recreation ground to the inhabitants of that town. The ground is situated within five hundred yards of the market-place, and is on the banks of the Derwent, on the east side of the town. It is six acres in extent. Mr. Bass bought it from the corporation at a cost of £3,000, and has spent nearly £1,000 more in fencing and in other ways preparing it for a recreation ground. The town authorities undertake to keep it in order, to embank the river round the ground, and to make a promenade on the river side, shaded by limes, elms, and beeches. The ceremony of presentation was gone through on Saturday last at a special meeting of the town council. Afterwards a procession was formed, and after parading the streets, which were crowded at all points, reached the ground, where at least twenty thousand persons had assembled. The mayor and Mr. Bass addressed the multitude, and afterwards there were amusements, including gymnastic performances, foot-races, &c. In the evening the mayor gave a grand banquet to the members for the county and borough, the corporation, and the magistrates.

ELDER VER-S GRAPE.—Jerrold's joke about the old port and the elder port will be unpleasantly recalled to "crusty" drinkers by the following paragraph on the manufacture of Portuguese wine, from a note by our Secretary of Legation at Lisbon: "All port wine hitherto exported for the English market is largely mixed with brandy, and is composed as much of elder-berries as of grapes. The way in which what in England is called port wine has hitherto been manufactured for the London market is this: The Paiz de Venhaterio abounds in elder-trees; the berries of these trees are dried in the sun or in kilns. The wine is then thrown on them, and the berries are trodden (as previously the grapes) till it is thoroughly saturated with the colouring matter of the berries. Brandy is then added in the proportion of from three to sixteen gallons to every pipe of 115 gallons. This is the composition of all the port wine hitherto drunk in England. No pure wine, no wine not thus specially adulterated for the English taste, was allowed by the Government Committee of Tasters to pass the bar of Douro before the year 1865." The writer of the above note is, we may mention, Mr. Robert Bulwer, son of Lord Lytton, but better known to the public as Mr. Owen Meredith, under which name he has published several volumes of graceful poetry.

ROYAL BOTANIC SOCIETY.

SECOND GREAT EXHIBITION, WEDNESDAY, JUNE 19.

(Concluded from p. 264.)

STOVE AND GREENHOUSE PLANTS comprised a considerable number of fine-foliage subjects, and the usual profusion of everlastings, ericas, ixoras, and statices. The principal contributors in the class for ten stove and greenhouse plants were Messrs. Peed, J. Wheeler, and W. Kemp, who were placed in this order of their names. Mr. Peed, gardener to Mrs. Tiedwell, brought a fine example of the somewhat scarce *Ixora Griffii* hii, making a brilliant effect with its finely developed orange-coloured flowers. Mr. Wheeler, gardener to J. Phillpot, Esq., presented a good *Bougainvillea glabra*, admirably done and the best plant we have seen this season of *Clerodendron Balfourii*, which sparkled all over with its creamy white and intensely crimson flowers. Mr. Kemp, gardener to Earl Percy, embellished his fine group with a plant of the lovely *Leschenaultia biloba* major, the finest blue-flowering plant known for greenhouse cultivation. In the class for eight, Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, took first place with noble plants, his *Dipladenia splendens* being a model of clever cultivation. Mr. Wilkie followed close with the rather new and most beautiful *Dipladenia amabilis*, and just such a grand *Ixora javanica* as was worthy to match his *Medemilla* at the previous show. In the trade classes, Messrs. Lee, B. S. Williams, Rhodes, Baxendine, and Glendinning, were the principal exhibitors. The competition in the class for six was equally spirited; Mr. Ward, gardener to J. F. Wilkins, Esq., Leyton, and

Mr. Smith, gardener to C. Anderson, Esq., Norwood, being the winners in the order of their names. Glancing through our notes, in which we have the names of nearly all the plants shown, we find that the following were the most important in these several classes, in addition to the few above mentioned:—*Ixora coccinea*, *amboynensis*, *aurantiaca*, and *alcofolia*; *Allamanda grandiflora*, *Schottii*, and *nerifolia*; *Dracophyllum gracile*, *Hoya bella* and *carnea*, *Phaenocoma prolifera* Barnesii, *Statice profusa*, *macrophylla*, and *Holfordii*; *Pleroma elegans*, *Acrophyllum venosum*, *Aphelexis humilis* and *purpurea*; *Prostanthera lasiantha*, *Bignonia grandiflora*, *Hedera tulipiferum*, *Polygala cordifolia*. In the trade classes for fine-foliaged plants, Mr. B. S. Williams distanced all competitors with magnificent groups, comprising the graceful and richly coloured *Croton angustifolium*, *Anthurium magnificum*, *Dasyliroton acrotrichum*, *Alocasia Lowii*, and other fine subjects. Messrs. Glendinning and Son took the next place. Mr. Williams was again in the first place with exotic ferns, and in the amateurs' class Mr. Taylor, gardener to J. Yates, Esq., Highgate, was the first exhibitor. In these classes there were fine examples of palms, pandanads, yuccas, aloes, cycads, and caladiums. The following selected from the whole appear to be especially worthy of mention:—*Theophrasta imperialis*, *Pandanus utilis*, *Cissus discolor*, *Alocasia macrorhiza variegata*, *A. metallica*, and *A. zebrina*; *Caladiums Chantinii*, *Bellemei*, *Wightii*, *Houlettii*, and *marmoratum*; *Cibotium princeps*, *Gleichenia semivestita*, *spelunca*, and *dichotoma*; *Lomaria gibba*, *Woodwardia radicans*, *Todea africana*, *Marattia elegans*, *Davallia bullata* and *dissecta*; *Adiantum formosum*, *pedatum*, *cuneatum*, *Farleyense*, and *tenerum*; *Phlebodium aureum*, *Platycaerium alcorni*, *Microlepia strigosa*, *Pteris argyrea*, *tricolor*, and *albo-lineata*. One of the finest ferns in the entire exhibition was a *Nephrodium molle corymbiferum*, shown by Mr. Carr, gardener to P. L. Hinds, Esq., Blythe. Messrs. Ivery and Son showed a good group of hardy ferns, as did also Messrs. Edwards and Son and Messrs. Kemp and Carr.

MISCELLANEOUS.—*Fuchsias* were fine; we have not for a long time past seen the equals of Mr. Brockwell's pyramidal plants, to which the first place was awarded. Mr. Weston presented beautifully finished plants of smaller size, and Mr. August made a respectable appearance. Mr. Brockwell has taken a position which we hope will tend to revive an interest in the fuchsia, for there has been somewhat of a falling off in competitions of late years; and we remember that we were indebted to Mr. Weston for beautiful specimens when few else appeared anxious to do the subject justice. Mr. Brockwell's varieties were *Sensation*, *Wiltshire Lass*, *Madame Cornelissen*, *Puritani*, *Lord Elcho*, *Fair Oriana*. *Roses* were shown in pots in a beautiful condition of freshness and finish by Messrs. Paul and Son, of Cheshunt, and Mr. Terry, gardener to A. Puller, Esq., Ware. Cut blooms were shown by Mr. Mitchell, of Pittdown, Messrs. Paul and Son, Mr. Fraser, Mr. Cranston, Messrs. Ingle, Marcham, Hollingworth, and others. A few azaleas still full of bloom were shown by Messrs. Peed, G. Wheeler, and Ivery. Mr. Bull put up fifty plants of *Lilium auratum*, showing not only the full splendour of its glorious flowers, but how admirably it may be grown in small pots. We may properly conclude this paragraph by mention of a pretty group of plants displayed by Messrs. E. G. Henderson and Son, combining new varieties and presenting them in a novel manner. The group was arranged in the form of a bed with an edging of small centaureas with blocks of the Golden Feather *Pyrethrum*, and of various kinds of tricolor geraniums. This was carried out in much the way we suggested at page 303 of last year's volume (July 7, 1866), but without staging of any kind, as a grass bank was made use of for the purpose.

NEW PELARGONIUMS.—From Messrs. Dohson and Son, Isleworth, a series of fancy varieties, all worthy of notice for their beautifully formed flowers and decisive colours. *Achievement*, one of the best-formed fancies, far in advance of the average best in cultivation; top petals lively magenta rose, lower petals blush with rosy veins; first-rate. *Silver Star*, like *Silver Mantle*, but without the spots on the bottom petals. *Homer*, small flowers, rich reddish magenta, in the way of *Sarah Turner*. *Number 1*, in the way of *Sarah Turner*, but a very highly-finished flower, with clear white throat; first-rate. From the same, a series of show varieties: *Lord Derby*, top dark, bottom rich lake; large and rough. *Prince Imperial*, lower petals a mixture of pinky red and salmon, top maroon, the flower large, smooth; every way first-rate. *Standard Bearer*, large, with curly petals, bottom rich lake, top dark, heavily veined. *Silver Queen*, white, with pretty carmine blotch on top petals; not round enough or smooth enough for the present day. *Hippia*, lower petals white, top pinky flesh, with small maroon spot shading to lake; likely to prove a valuable exhibition variety—at all events, very promising as shown.—From E. B. Foster, Esq., Clewer Manor, near Windsor, a series of show varieties: *Orion*, orange-scarlet, with dark blotch on top petals; very showy for conservatory decoration. *Robin Hood*, large, flat, smooth, bottom petals clear pinky rose, top fine blackish maroon shading to rich lake, edge pink, whitish throat; very fine. *Autocrat*, large, good form, lower petals prettily veined with carmine on a blush ground, top maroon shading to a light edge, clear white throat; a very beautiful flower. *Empress*, extra fine form and quite smooth, though showing an occasional fold in the top petals; bottom salmon-pink, top black shading to lake, white throat; a fine flower. *Joan of Arc*, a beautiful dark top shading to richest crimson, bottom rich lively purple-rose, white throat. *The Cardinal*, petals too long, fiery lake shading to carmine; very showy. *Vesta*, large, with broad petals, bottom pale salmon-pink, top rich lake shading to a pale edge, white throat; not smooth enough. *Troubadour*, bottom clear salmon-flesh, top flesh with a blotch consisting of maroon rays, white throat; a large, smooth, broad petalled, and very superior flower. *Sœur de Charité*, lower petals deep salmon, overlaid with thin lines of lake, fine dark top; a flower of superior form and smoothness, and highly attractive in colouring. *Purity*, long pot, but otherwise good; bottom clear rosy pink, top dark shading to crimson, white throat; a pleasing flower. *Bacchus*, bottom very rich lake with maroon lines, top maroon, white throat; far from perfect in form, but extraordinary in colouring. *Hermit* and *Prince Consort* are fine varieties, already described.—From Mr. Fraser, Lea Bridge Road: *Marksman*, large and fine form, top petals extra large, quite black shading to a broad crimson margin, bottom salmon-pink, whitish throat.—From W. Beck, Esq., Isleworth, a series of show varieties, comprising *L'Emperour*, *Beauty*, *Aspasie*, *Filomena*, *Memnon*, *Calypso*, *Aurora*, *Camilla*, all of which have been described in previous reports.

NEW GERANIUMS.—By adopting this heading, in defiance of technical rules, we are enabled to separate the zonal, zonate, inquinans, variegated-leaved, tricolor-leaved, and other of the varieties of pelargoniums that are sometimes classed as "bedding pelargoniums," sometimes as "zonate

polargoniums," sometimes as "scarlet" or "horseshoe" geraniums, from the "large flowered" section for which nobody can find a distinctive name, but which are best known as *Pelargoniums*, while these are best known as *Geraniums*. Probably the grandest contribution to the exhibition in this class was Messrs. James Carter and Co.'s tricolor-leaved variety *Prince of Wales*. In this we have brilliant gold-yellow for perhaps the first time, and abundance of red in the zone, the leaf being extra large, extra flat, and the plant altogether a marvellous example of leaf-colouring. *Princess of Wales*, from the same, is one of the most brilliant of its class.—From Messrs. E. G. Henderson and Son: *Lady Cullum*, splendid in its profusion of red colouring in the zones. *Minnie*, a miniature tricolor, with beautiful colouring. *Little Pet*, small leaves, silvery margin, reddish zones. *Harry G. Henderson*, a few leaves very rich in colouring, the remainder with green margins and disks and dark zones; scarcely prudent to show any variety in this dual state. *Model Outline*, very rich lemon-yellow margin and bright red zone; one of the finest in this new batch. *Fair Emily*, pale yellow margin, fine dark zone. *Jenny Wren*, a silver tricolor, quite a gem in style and colouring. *Bridal Wreath*, a white-flowering ivy-leaved variety; the top petals have red lines at the base. *Brilliant Gem*, in the way of Mrs. Pollock, with abundance of red in the zone.—Mr. Tirebuck, of Luton, Beds., sent *Dandy*, a new style of silver tricolor, the margin white, the zone dull chocolate-brown, with patches of red. *Queen of Spain*, a fine Luna-like variety. *King of Hungary*, of the same class as the last, but acquiring a pale lemon-yellow margin, and a rust-red tone in the zones of the old leaves. *Brown Dwarf*, of the same class; tolerably good, perhaps. *Flora McDonald*, a good one, with decided yellow margin and disk, and rich crimson zone.—From J. Potto, gardener to B. D. Colvin, Esq., The Grove, Bealings: *Mr. Sidney Colvin*, colours very rich, the edge yellow, the zone black and red, disk dull green with triangular yellow base; a rather rough-leaved variety, but splendid in colouring. The label announced that the seed was sown Oct. 3rd, 1866; the plant had seven large leaves and four small leaves in the tricolor style, beneath which were a few of the original dark-zoned green leaves. Supposing the seed to be raised in 1866, we may allow just one year for the whole process of raising a good tricolor.

In other classes the following were noted:—From Mr. Tirebuck: *Felix*, a good nosegay variety, with peach-coloured flowers. *Emily Martin*, a neat little zonate kind, with brilliant scarlet flowers of very superior form; first-rate. *Queen Adelaide*, zonate, dwarf habit, flowers salmon-scarlet; good.—Mr. Bull showed the ivy-leaved variety, *L'Elegante*, in two distinct states; in one, the leaves have a bright reddish pink margin, in the other, a creamy margin; the differences are due to the degrees of solar light to which they were respectively exposed—a constant exposure close to the glass producing the red tint, and a less degree of light the creamy shade. From the same, *Lustre*, a superb zonate variety, which appears to be superior to the far-famed Dr. Lindley; whether or not, it is one of the best yet shown.—From Messrs. Downie, Laird, and Living: *Comet*, a nosegay, fine dark zone, and huge truss of crimson scarlet. *Hon. G. Hardy*, a fine nosegay, with huge truss of deep scarlet. *Floribunda*, a nosegay, with immense trusses of orange-scarlet of the same shade as Harkaway.—From Mr. Shenton, of Biggleswade, a series of zonate varieties of no particular excellence; also *Setting Sun*, a nice tricolor, with rich lemon-yellow edge, and broad zone of dark brown, with a few patches of red.—From Mr. G. Smith, of Hornsey Road, the now famous *Le Grand*, which has been so frequently and so variously described that we venture once more to say that, so far as we can understand the case, the prevailing colour is scarlet, with a decided violet shade. It is undoubtedly the finest nosegay yet produced, and to be without it is to be in a state of destitution. From the same, *Grand Duke*, in the same style as *Le Grand*, but the petals are broader, and the colour is scarlet with shade of orange. From the same, *First Favourite*, a large-flowering zonate variety, with extra broad petals, the flower circular, flat, smooth, and finely fin-bed; colour light scarlet.—From Mr. Davison, gardener to Miss Mason, Highgate Park: *Emily*, a dwarf-habited variety, like *Pink Tom Thumb*, and probably as good.

NEW ROSE.—Mr. Ingram sent from Frogmore a new hybrid perpetual, named *Miss Ingram*. The flowers large, globular, and immensely full; pale pink in the centre, shading to white outside, in the way somewhat of *Madame A. de Rougemont*. To this was attached a label setting forth that the tree withstood the frost of January last without harm.

NEW AMARYLLIS.—Mr. B. S. Williams brought forward a dozen fine varieties of amaryllis, some of which we believe to be new. As it is but seldom these flowers are exhibited, we shall describe this set, putting in italics the names of such as we consider new. *Robustum*, a fine large flower, with broad petals; colour crimson washed over with orange. *International*, very large, a curious shade of dull red with grayish lines and edges. *Graviana*, orange-red, with clear pale green central stripe and greenish throat. *Holfordii*, lake-red with greenish stripes and lines; very handsome. *Regina*, splendid self, orange-red. *Magnifica*, dull brownish red, regularly marked with gray lines, the throat green. *Ma Chère*, pale red, broad greenish stripe; only middling. *Insignis*, very broad petals opening to a flat face, and reflexing at the points; brilliant scarlet, with clear white central stripe. *General Garibaldi*, grayish white shading to pale green throat, thinly marked with lines of purplish red; very distinct, but not very good. *Magnifica purpurea*, very large and fine; crimson-red with narrow greenish white stripe; a splendid variety.

NEW LOBELIAS.—In Messrs. E. G. Henderson's pretty group were some attractive varieties of *Lobelia erinus*. *Pumila* is very dwarf, the flowers minute, the colour lavender blue; the tiny flowers of this variety are produced in such profusion as to form a kind of cloud of soft colour spread over the whole plant. *Indigo Blue* is a beautiful variety, with flowers of average size; the colour indigo with distinct white eye.

BLANDFORDIA CUNNINGHAMII merits mention with a word of praise as a wind-up to this report. It is one of the best of recently introduced greenhouse plants, and merits the special attention of the collectors and cultivators of choice subjects.

S. H.

DECLINE OF THE AGRICULTURAL SERVICE.

At a meeting of the Leicestershire Chamber of Agriculture, held at Leicester a few days since, Mr. Inett, of Asfordby, a farmer of high standing in the county, in reference to the age at which children should be employed, said he wanted to know how men with large families were to feed their children until they were thirteen years of age. If they were to educate them till they were thirteen, they could not keep them from eating. He asked whether they did not think boys were more likely to

make efficient labourers if they went to work at ten than at thirteen? They were less likely to associate together, and to get into vile habits, than they were at thirteen. He should be sorry to say anything against education, but it had not had that influence upon the agricultural labourers that was expected; in fact, the influence had not been for the better, but the worse. He had been a farmer now for fifty years, and he said, without fear of contradiction, that the labourers nowadays were a worse class than they were fifty years ago; they were more dissatisfied with the position in society in which they were placed; they were not so industrious, not so honest—altogether a different class of men to what they were then. They thought more of themselves and their families, tried to cut a bit or figure than their masters in the village; they thought nothing about their masters' interests, and not only did not keep their lands from picking and stealing, but were very much given to poaching. Then, again, he said, education had done nothing to advance the efficiency of the labouring population. With the exception of an odd instance here and there of a skilled labourer, who had been brought out by the extra improvements the agriculturists had adopted, there were many occupations that they never saw attempted nowadays. There were very few men who tried to cut a hedge or shear a sheep. Probably the farmers had themselves to thank in some degree for this, because there was a time when they used to keep from three to five men in the kitchen. They went there as boys, and served a sort of apprenticeship. They were kept there till they knew something; but now they went from bird-scaring to plough-driving, and became labourers. If they wanted them to do anything with a spade or a scythe, not half of them could do it. As he had said, they had to thank themselves in some degree for this; for just as the landlords wished to clear their estates of poor-houses, the farmers wished to clear their kitchens of the plagues there were there. He could not think education had done anything for the agriculturists.

A HOLIDAY IN THE WEST.

PART IV.—MR. ROBERT VEITCH'S NURSERY, NEW NORTH ROAD, EXETER.

I quite understood the story of the poor chair-mender, who was asked what sort of holiday he should like, and replied, "a good lot of chairs to mend," when, on a very sunny morning in the latter part of the month of April, I caught sight of the inscription, "R. Veitch's Nursery," while taking a stroll for the good of my health in the New North Road, Exeter. I felt as pleased as a boy who finds sixpence, or a chair-mender with an extra lot of work to do, for how could I find a better entertainment in that reservoir of ennui, the city of Exeter, than in making a pleasure of business, and giving myself to the old game of a hunt through a nursery? The "constitutional" that some people talk so much about is a very good institution, no doubt, but I incline to the opinion that the best constitutional is hard work, and the man who cannot look upon his work as a sort of joke, or as an amusement, or as a trick for the entertainment of the mind and the improvement of the appetite, is a poor dull wretch who deserves to have no chairs to mend, and who, if he goes about at all, ought to have handcuffs on to keep him out of mischief. The accursed nonsense of considering everybody else's lot better than our own is the cause of nine-tenths of the discontent and envy that sours and darkens the world. I fancy I can discover what is the best lot for any man, and that by optimism rather than by philosophy. The best lot is that which providence has apportioned you, and chronic discontent is practical atheism. A strike for wages is right, and a change of occupation is right, and so are reforms and revisions in politics and morals, if founded on justice and reason. So we cannot take Pope's doctrine and swallow it whole, "Whatever is, is right," believing that as we find things so we must leave them. No; but your perpetually grumbling grizzled phiz, who sees in every man an impediment or barrier to his own success, deserves to have written on all his walls, and scratched on his looking-glasses, and neatly printed on a card and thrust into his pocket-hook, and pasted inside his hat, that passage wherein the Bastard bullies Hubert in *King John* (iv. 3)—

If thou want'st a cord, the smallest thread
That ever spider twisted from her womb
Will serve to strangle thee; a rush will be
A beam to hang thee on; or wouldst thou drown thyself,
Put but a little water in a spoon,
And it shall be as all the ocean,
Enough to stife such a villain up.

Well, let's see, where are we? Oh, to be sure, making a pleasure of business—what a virtuous proceeding! How admirable an occasion for giving those malcontents a kick who grumble at their work as if existence were of necessity a penial condition, and how very nicely we wound it up with the aid of Shakspeare, didn't we? This moralising may be supposed to take place at Mr. Veitch's entrance gate, and the delay in turning the latch may be supposed to arouse his suspicion that the party pausing there has something to sell; and we may next suppose he is about to bawl out, "We don't want any," when he makes the grand discovery—"but we draw a veil over the touching scene," as Mr. Punch would say, remembering how, during the last exhibition season, my esteemed friend M. Jules Croixlecharme entered a shop in Cheapside, intending to make a large purchase, and of course made a profound and polite obeisance to the gentleman behind the counter, and was greeted with the admonition to "Go on; you're not wanted here." Mr. Robert Veitch thought I had just come from London to look after *Adiantum Farleyense*, and began to hurry me up the garden; but I told him I had come without a purpose, except to make sure that the city of Exeter had not lost all the Veitchs, because in such a case the city must go to ruin quickly, and the more quickly the better. I delayed seeing *Farleyense* for the sake of a look round, or rather a look up; for this nursery is in a series of platforms or terraces, and the walk from the high road is a series of ascents by gentle slopes and flights of steps. Going upstairs is scarcely a pleasant pastime, but one advantage results from the peculiarity of the site, and that is, that seen from the public way the greater part of the nursery is displayed to view like a picture in outrageous though accurate perspective. This is one of the prettiest nurseries imaginable, and when I dropped in there was a great blaze of *Rhododendrons* and *Kalmias* in the open air, these things being about a month in advance of ours about London. I was not long in discovering amongst the sea a *rhododendron* particularly worth notice, and learnt that it was an unnamed seedling; say this was the 24th of April, and this *rhododendron* was full out, and you perceive that it has one quality to fit it for pot culture. But it was in splendid health, with ample and handsome foliage and huge trusses of finely-formed flowers, the colour scarlet shading to crimson, and

therefore fit for exhibition, and hardy enough doubtless for the garden anywhere. The name is to be *Duke of Edinburgh*, and it is to have a place in our list as one of the best of the season. Coniferous trees were very beautiful, and in very few cases hurt by the winter. Under glass a fine *Medenilla*, the next best perhaps to the fine one shown by Mr. Wilkie at Regent's Park the other day. *Correa cardinalis*, a good old plant one now but seldom meets with, but it ought to be everywhere except in the garden of a friend of mine, who hates everything that lasts beyond a fortnight, for this *Correa* is nearly always in bloom. *Luculia gratissima*, too, well done, and valuable, and propagated as easy as a soft-wooded plant. Query, for anybody and everybody, if root-pieces are not better than young shoots? *Kalmias* in quantities in pots, and a great sale for them. The old subject, how to grow *K. latifolia*, which is the most useful, to bloom all over like gauze or muslin. Mr. Veitch says they do well at his Broadcliffe nursery, where the soil is a hungry sort of peat, and the plants are rather roasted in the autumn. Go to see Farleyense as a finisher, and find a child thereof in a quite new form and style of *Adiantum*, intermediate between Farleyense and *Capillus veneris*, or perhaps between Farleyense and *Chiliense*. It has large pinnules, the upper margins of which are nearly semicircular and regularly but not deeply crenated, and the inferior margins are irregularly wedge-shaped, the topmost pinnule in every case being quite regular and in the form of an escutcheon. This we named *Adiantum scutum*; whether it is a hybrid, a sport, or a species I cannot pretend to say, but its direct descent from Farleyense, its obvious distinction from that, and the uniform character of all the plants—the stock is considerable—are facts suggestive that it is a seminal variety of Farleyense, and most likely a true hybrid. But no matter about its secret origin, Mr. Veitch is the fortunate possessor of an *Adiantum* that will take rank with the best varieties in cultivation, and surpass many that are considered highest in the rank of excellence for exhibition. I now take my farewell of Exeter, great emporium of Dolldrums; if it were not for Mr. Pince on one side and Mr. Veitch the other it would surely vanish away, save and except the Cathedral, and the portico of the Guildhall, which would grandly mark the site of the once peaceful abode of the family of Dryasdust. S. H.

A SELECTION OF VEGETABLES, WITH HINTS ON THEIR CULTURE.

I am induced to continue the subject of the paper commenced at page 256 from having observed, in a garden which I have visited in the interval, that which goes far to confirm the truth of the remarks there offered on the disappointment which often follows the attempt to prove the qualities of any particular seed in gardens of limited extent, and the importance, therefore, in such gardens of growing only those varieties that are universally regarded as the best. In passing through the garden to which I have referred, my attention was directed to three rows of early peas, each row being a distinct variety. Although these peas were advertised by their respective vendors as being each the "earliest in cultivation," yet it was evident there were several days' difference in their respective fitness for gathering. As the kitchen garden was very small as compared with the other portions of the ground, and as the yielding of each row would afford but a very small dish when fit for use, was it not a mere waste of time and space in thus striving to test their comparative merits, especially as these pages have been already occupied with the result of the trial of the different peas? For what purpose expensive experiments and elaborate reports by the most competent of persons, if private growers do not take advantage of the results arrived at? I shall now refer to a few more kinds of vegetables that should, between this time and the autumn, have our best attention for future winter and spring supplies.

Celery.—Of this esteemed vegetable few persons care to grow the very large varieties as formerly, the desire being to obtain close, thick, compact heads, that can be quickly blanched with considerably less labour than attends the large kinds. The dwarf varieties have proved the best flavoured. Having grown nearly all the sorts that have been introduced during the last twenty years, some of them have become great favourites with me for general cultivation. I had in my previous situation to contend with a cold wet soil in winter. I have therefore given special attention to those which are less likely to suffer from the effect of wet and frost, and which would occupy the least space when growing. Amongst the white celeries nothing surpasses *Turner's Incomparable*; it is very hardy, and capital for every use. As a substitute for sea-kale it is excellent—in fact, cooked any way it makes an excellent dish; as it does not grow to a large size, it can be planted with advantage two or three deep in wide trenches, thus economizing the ground. *Cole's Crystal White* is a little larger, and is somewhat earlier, and altogether a very good celery. Of red varieties *Hood's Imperial Dwarf* is a good companion to *Turner's Incomparable*. *Williams's Matchless Red* justifies all that is said of it in the description of this particular variety; its flavour is very superior, and it possesses the valuable property of being fit for use for a very lengthened period, not showing the least disposition to run to seed till late in the spring.

Endive.—There are not many varieties of this delicious salad; but for small gardens, of the curled varieties, the *French Moss* is decidedly the most preferable; it does not grow so much to leaf as the old green curled. In cultivating this vegetable, I sow it in drills, on a south border, the rows about one foot apart, and afterwards thin them out to about nine inches from plant to plant. It

produces very compact heads. If you wish to preserve it during the winter months, you can sow the seed in an open part of the garden. Before winter it must be taken up carefully with some of the earth adhering to the roots, and planted thickly together in a cool frame; and the crowns should be kept very dry, not allowing rain to fall on them, as that and frost together will cause them to rot rapidly. The *White Lettuce-leaved*, or *Batavian Endive*, is a capital substitute for lettuce during the late autumn months, and by many persons they are mistaken for lettuces. They grow very large and fine, but unless they are tied up early, so as to be thoroughly bleached, the taste will be bitter. They should be used before frosty weather commences, as they are not so hardy as the green curled varieties of *Lettuces* for standing out of doors during the winter months. We have not at present anything to surpass for hardness of constitution the well known cabbage-lettuce, the *Hammersmith Hardy Green*. By making two sowings of it, that is at an interval of about a month, you may supply the table with lettuce till Christmas, and then again early in the spring. The same treatment in sowing and choice of aspect, &c., is recommended as in the culture of the endive. For sowings in the autumn, and afterwards to be pricked into frames to be planted out in the spring, for late spring and early summer use, nothing has yet proved with me to equal the *Brown Dutch Cos Lettuce*. If a row is planted parallel with the garden wall, within a few inches of it, and attentively watched, so that leaves do not accumulate round their stems to harbour slugs, &c., they are pretty sure to survive the hardest winter. But if slugs get amongst them, there will be a number of blanks created. The soil should also be made firm about their stems to prevent canker. By these attentions, and an occasional sprinkling of lime amongst them, you may obtain good eos lettuce very early in the year.

Turnips.—They say it is seldom we can get a garden turnip to equal those which are cultivated in the fields; they either grow too rank or the flavour is indifferent. The sort which has been with me a favourite for many years past is the *Red-top American Stone*, or *Red-top Mouse-tail*. I first obtained it from Messrs. Sutton, seedsmen, of Reading, and since that, when I could get it true, I have grown no other variety, as I find it proves an excellent variety for both early and late use; and it keeps well if taken up previous to sharp frosty weather, and stored away with the other culinary roots. JOHN F. McELROY.

ON ACCLIMATIZATION AS THE MODE IN WHICH THE EARTH HAS BEEN PEOPLED.

By Mons. RUFZ DE LAVISON.

Believing the proceedings of acclimatization societies to be of the greatest importance to the progress of the natural sciences, and, through them, to our social well-being, we have devoted no small portion of this journal to the making known their transactions at home and abroad. Like all new institutions, they have to contend with the sloth of the unenterprising and the ignorance of the ill-informed. They are opposed on the ground that, being an interference with the ordinary processes of nature, acclimatization cannot be expected to produce more than a limited temporary result. A fatal objection, truly, if well founded.

But the theory and practice of these prosecuting acclimatization rest on what they deem the incontrovertible fact that nature is their instructor and guide, and that the successes which they have achieved are to be ascribed to the docility with which they have listened to her teaching.

One of the most eloquent expounders of this main doctrine of the acclimatizationists is M. Ruzf De Lavison, with whose merits as a lecturer at the Garden of the Acclimatization Society, Paris, the readers of our annotated translations are familiar. We think his lecture on acclimatization as the doctrine of the peopling of the earth such an admirable reply to the objection that acclimatization is an unnatural novelty, that we shall proceed to translate nearly the whole of it.

Often, with history in my hand, and actual experience to support it, it has been proved to you that what we are doing has been done in all ages, and that we follow a course commenced in the beginning of the world, and that man has always practised acclimatization; that we merely profess to regulate, stimulate, and generalize what had heretofore been done, as it were, in an unconscious, instinctive, isolated, and capricious manner; that we wish to give to attempted acclimatizations the help and the impulse which civilization has given to many of the works of our era; or, to speak more correctly, that acclimatization and civilization are equivalent words, meaning the same thing—namely, progress. As to all this, I do not believe that your minds are in any doubt. I wish now to show you that the doctrine of acclimatization is in equal accordance with science and tradition; that it adapts itself to the great cosmogenic theories of science; that the school of acclimatization has undertaken nothing contrary to nature—nothing which is not in perfect conformity to the laws which appear to have presided over the actual arrangement of things on the surface of the earth.

History and science now agree in acknowledging the primitive union of creation as being, of all the doctrines as to the peopling the earth, that which most agrees with the subsequent arrangement of things, and with their actual condition. Here is that doctrine. All individuals of the same or even of allied species have descended from one first parent, and have therefore originated in the same stock. However distant and isolated the parts of the world in which they are now found, the primitive species must, in the course of successive generations, have passed from the one to the other of these points by propagating and multiplying nearer and nearer. The animal and vegetable kingdom is, therefore, merely an emanation and evolution from a small number of primitive types.

This is another point not less generally admitted. All organized

beings, under the influence of a power whose reality it is easy to understand, but whose modes of action are not always perceptible, tend, in the course of generations, to modify their forms, and even their structure, according to external circumstances, such as locality, food, and meteorological and physical agents; hence all the variations observed in nature. Man does not produce variability; he merely exposes, often unintentionally, organized beings to new conditions of life, and then, nature acting on the organization, the result is new conditions of life. Human art in its limited sphere can, by numerous examples, demonstrate how a modified animal or vegetable may differ much in appearance from their common progenitors; it can, so to speak, follow with the finger and the eye the progress of the transformations. The variability of primitive species is, therefore, still the doctrine most generally admitted amongst naturalists.

This variability of primitive species is governed by certain laws. There is first the hereditary law, which tends to preserve them in their primitive forms, so long as their conditions of living are the same, and to bring them back to those typical forms whenever they have deviated from them through any special accident. This law of recall to primitive forms has been termed *atavism*. Atavism is the safeguard of the fixity of types. It is also a means of remounting to the primitive species, and of demonstrating them.

These two words, *variability*, *hereditariness*, are sufficient to explain the present aspect of the organized world and the whole creation!

More individuals, no doubt, come into existence than can live. Among the countless beings which dispute the possession of the earth, and wish to see the light, there is endless and universal strife as to the means of existence! each wishes to preserve not only its individual life, but its life as a species—that is, to multiply its race. From this universal strife it results that, if by any accident a being varies, however slightly, but in such a way as to benefit it personally, and adapts itself better to the time or place where it finds itself, and acquires a superiority in form or vigour, this superiority, reproduced by the powerful law of hereditariness, and multiplying through the race in geometrical ratio, will end in giving it the predominance over the inferior races not having the same advantages. These pressed upon, pushed back, smothered, will eventually be exterminated. Hence, for one existing species which has been preserved, many must have disappeared. Thus beings endowed with life go on modifying, consolidating, and perfecting themselves; thus are new specific types being created at the expense of the old; thus by degrees, and nearer and nearer, the face of the organized world is renewed. This law of the predominance over each other of individuals and races has been recently termed *natural selection*. Mr. Darwin, in his very remarkable work, entitled, "On the Origin of Species, or the Laws of Progress among Organized Beings," has developed all the results with much power and learning.

It is not necessary that the variations be considerable; as they act by accumulation, the slightest of them are of some use to their possessor. A grain, as it were, in the balance is enough to determine which individual shall live or which shall die; what variety or species shall increase, which shall continue, and which shall finally be extinct. This is the principle of the incessant work of renewal going on over the surface of the earth.

We cannot deny that nature has this power, when we every day see it exercised by man. Man thus adapts to his advantage or pleasure either plants or animals, by accumulating on an individual the properties which render it suitable for the uses which may be made of it, and by obtaining in the race the reproduction of that accumulation in virtue of the law of hereditariness. Hence what contributes to the improvement of the domesticated races. Such a result is obtained even in ignorance of the effect produced; it is sufficient, without thinking of altering the race, that we do that which is done every day—that one shall put aside and preserve the individuals which appear the best for breeding. If man, with patience, can select and reproduce the variations which are most useful to him, why may not nature select the variations most useful to her living productions by placing them under changing conditions of living? What limits can be assigned to this power, acting through long ages, nearer and nearer every moment, in spaces and numbers indeterminate?

Such is the doctrine by which we now explain the variety of species which people the surface of the earth.

Proofs for the demonstration of this doctrine are not wanting; we know the means by which nature as well as man obtains these results. By climate, by soil, by cultivation, by habit, by the exercise or the non-exercise of certain organs, we are daily obtaining great transformations. We convert the dwarf and stunted tree of the mountain into the great and spreading tree of the plain. By means of the same modifications we trace to the same origin the pug-dog and the strongest dog; all animal and vegetable nature may be retouched, modified, transposed, at the will or caprice of man!

"When listening to these words of Lord Somerville, we may," says Mr. Gubler, "have an idea of the power which man exercises upon the plastic properties of the animals submitted to his empire." Speaking of breeders of sheep, he observes: "It looks as if they had sketched a perfect form on a wall, and then given it existence." Sir John Sebright, the greatest rearer in Great Britain, speaking of his department (pigeons), said that "in three years he could reproduce any given plumage, but that six were needed to obtain a head or a bill."

"Not only do types modify according to circumstances, but man can at will determine the nature of these changes of form by taking advantage of natural tendencies, exciting them as required, directing them, or finally exaggerating them, according to his profit or pleasure. The metamorphosis continues, and is constantly established by passing from one form to another, in the continued birth which we see going on through all organized nature, under the impulse of the powerful means at her disposal."

Can we imagine a doctrine more in accordance with that of acclimatization than this successive transformation of beings from the point of their origin even to the ends of the earth? Was there ever a more logical sequence?

Under the able hands of modern horticulturists we are constantly seeing some new forms of flowers, vegetables, and fruits, at the expense of species more anciently developed. Any day you may see in our parks and courtyards how a small species of sheep, fowl, or pheasant can be changed into our large domesticated breeds. Nature herself, like an able gardener, gathers grains and germs in order to adapt them to circumstances suitable for them. By these analogies we can form an idea of the means she employs for adapting the animal and vegetable species to their new destinations.

But, it is said, these modifications are superficial and slight, and do not penetrate the organization of beings; they never act on that inner mode of being which constitutes their essence, and which insensibly tends to bring them back to their primitive form as soon as the disturbing force is changed. Neither the ovule, which, by impregnation, becomes capable of reproducing the animal, nor the different phases of its development, nor the structure of the being which issues from it, nor the relation of its organs, can be modified. In spite of the marvellous reusability of forms, says M. Decaisne, the true specific characteristics remain ineradicable.

But see how in our parks, under the influence of climate, the yaks of the Himalaya, and the goat of Thibet, and in general almost all wild animals, lose certain parts of their hair—the fine and double down, which, allow me the comparison, like our flannel vests, is found close to the skin; while the Senegal sheep have their short hair lengthened and curled, in order to supply them with a warmer fleece, to protect against the severities of the winter which they have to endure.

If nature only needs such slight changes for the accomplishment of her ends, must she, in order to convince us, set about overturning everything? If some have eyes that cannot see, must she descend to their infirmity? Is it not by these changes, small according to them, and feeble according to their feebleness, that she shows herself faithful to her plan? In order that there may be unity in the variety, is there not variety of forms without change of essence? Are we not constantly repeating as an axiom of universal observation, that nature makes no leaps—*natura non facit saltum*—so that we pass insensibly, and as it were without a transition, from one species to another, so that there are between them separations so slight as, at the two extremities of the scale of species, to efface distances? Have we not here, in other terms, a complete recognition of the insensible modifications employed by nature? "The effects of locality on organisms," Mr. Darwin observes, "are not always manifested by very apparent external changes. In plants and animals the adaptation may be effected by means of modification of function, the constitution of humours and the external structure, without any great alteration of the morphological forms. The organic type is preserved, but the temperament changes. In modifying themselves, the vegetable and animal species have a tendency to render their economy less susceptible to the injuries excited by the physical agents conspiring for their destruction, while they constantly furnish to them the means of existence."

Let us see how it fares with man, the most diffused, the best observed species. With respect to his bodily organization, man is assuredly an animal quite like any other. He is the king, the type, the compendium or model of animals, but he is an animal subject to all the external agents which act upon the nature of animals. Man, nevertheless, can live under all climates. We can follow him through all his migrations, past and present. We heed not those sceptics who deny the possibility of his being acclimatized on any part of the earth whatever. Well, a simple modification of the colour of his skin appears to be the only appreciable condition which nature requires for this adaptation. For all the differences presented, in different countries, in his organization, whether as to his form or his intellect, seem to result from food, or rather from the exercise or the defective exercise of his faculties, rather than from climate.

If it be said that this power of universal adaptation, so visible in man, is peculiar to him, and is explained by the manifold resources of his intelligence, which enable him to ward off the effects of climates, and to hinder the modification of his organization, I ask, if the stables, the courtyards, the greenhouses, the clothing even with which we protect animals and vegetables, the more stimulating food by which we maintain their vigour and excite their calorific power—that is, the power of engendering caloric in their own tissues—the training which we give them, the gradations through which we make them pass; if, in short, all those attentions which they receive from us, and which, as it were, place our intelligence at their service, be not of the same order and of the same power as those attentions by which man protects and accomplishes his own acclimatization in the different parts of the globe.

It is barely a century since the large chestnut tree was imported into Europe. It was at first reared in hothouses, because it was believed to be a native of the Indies. Later it was placed in a cold frame, then it was handed over to the open border, in the open air; and you know if large chestnut trees be not now acclimatized in Europe almost as much as man. We are unable to tell of how many other plants and animals as much may be said, and which are as much proofs of the power of acclimatization.

But it is said if the large chestnut tree and certain plants be acclimatized, and have fixed themselves in Europe, it is because they are the natives of countries whose climatic conditions are analogous. It is not veritable acclimatization, it is introduction, it is transplantation or transportation, that you are dealing with. What matters the world, if we succeed in giving to Europe the yak, the lama, the lophophore, antelope, the ignama of China, the lozo, the sorgho, and the textile urtie, as we have already given to it the turkey, the potato, the camellia, and so many other riches? Transportation and introduction are, no doubt, the first degrees of acclimatization; and reduced to that, to merely multiply and promote such doings, I say that acclimatization renders immense services to humanity.

Having undertaken to demonstrate a general proposition, I cannot stop much in giving the detail of particular facts. If man can be acclimatized under all latitudes, under the poles as well as under the torrid zone, it is equally true that his acclimatizations are very costly—so costly, that some ultra-sceptics go so far as to hold that most of the human species transported from their original zone cannot maintain themselves, and end in being extinct after a few generations; that, in short, man is not cosmopolite. Without adopting this ultra conclusion, we grant that, in the transportation of men, for one who succeeds and forms a stock, there are many who succumb and disappear. But it is not less true that some individuals, profiting by certain of the advantages from which natural selection derives so much, successfully resist the physical conditions which are contrary to others, and that it is from these individuals that there comes a progeny which adapts itself more and more to the soil each generation. Such is the result of all experience. The history of the Deluge and of Noah's Ark is a myth as well as a tradition. It is the principle, the starting-point of the doctrine of acclimatization. But I do not hesitate to affirm, that if with any animal species we took the same pains as with man—if we expended on it as much money and as much care—if, finally, we experimented upon equal numbers, we should arrive at the same results—that is, we should acclimatize that animal species under all latitudes. Do you remember what the different invasions and migrations of the human species have cost, and especially the slave trade? Have not all the domesticated animals

of Europe been naturalized in different parts of America at much less expence?

Our acquaintance with a common physiological fact is sufficient to explain the success of all transpositions of animal species. Under the influence of heat or cold we see certain parts of the organization diminish or develop, the skin become pale or dark, or rather injected and quickened in the circulation. The secretions are transposed, the temperaments change, the sanguine become bilious or lymphatic. The diseases are not the same, and indicate great changes of organization. Finally, the progeny sums up, as it were, and affirms all these changes; for the descendants of an acclimatized species bear the impress of their new climate quite as much as of their progenitors; all the European species which I have seen at the Antilles lose their shape and vivacity, without losing their usefulness.

It is now a trivial truth, known even to the most ignorant, that in the diffusion over the earth of the animal and vegetable species there have been great catastrophes. The ruins of a burnt house, Darwin observes, do not more clearly tell its fate than these forests and bones buried at different depths tell what has happened to them. All historical documents relate that certain animal, and even vegetable, species are no longer found where they existed formerly, whilst others which existed elsewhere are seen where they were not to be seen. Ancient species of the elephant and the rhinoceros were capable of enduring an arctic climate, while the living species are now tropical or intertropical.

As acclimatization, slow and progressive, such as we now see it, is insufficient to explain the extent of these revolutions in the peopling of the globe, we are obliged to suppose that there have been extraordinary cataclysms which might have reversed the existing order, and carried the north to the south, and the south to the north.

But how many other facts teach that it was chiefly by successive acclimatization, and by little and little, that the earth was peopled by the inhabitants which now cover it. Run through the length and breadth of the globe: to whatever continent you go, under the most diverse conditions of life, in spite of heat and cold, on mountains or plains, in deserts or marshes, most of the inhabitants in each of the great classes are closely allied, and present a physiognomy which seems to tell you that the one has been born from the other. You might give them as a motto the lines of the poet—

Facies non omnibus una
Nec diversa tamen, qualis decet esse sororum.

A naturalist, says Darwin, travelling from north to south, never fails to be struck with the manner in which groups of organized beings, specifically distinct, yet closely connected with each other, mutually replace and succeed each other. He sees analogous birds; their plumage is almost the same, their nests are constructed nearly in the same way, their eggs are of the same colour, and yet they are different species. The gradation is even more perceptible in the vegetable world. The productions of mountains and lakes are allied to those of the low or the sandy lands in the vicinity, notwithstanding the great differences of position.

Thus has been, thus daily is, effected the colonization of each station by the inhabitants of the region next to it, by means of migration of species combined with the power of modification and adaptation of these colonists to their new country.

It is thus that the most isolated and remote islands have a fauna and a flora resembling those of the nearest continents. All the plants and animals of the archipelago of the Gallipagos Islands, or the Island of Juan Fernandez, have the most striking resemblance to the plants of the neighbouring countries of America; whereas the organic populations of the archipelago of Cape Verd, and of the other islands of the coast of Africa, have an entirely African aspect.

These resemblances dispose us to think that in eras more or less remote these islands have all formed parts of the neighbouring continents, and that there must have been crossing places in all oceans, which have served as great routes of migration.

But we need not have recourse to these distant suppositions. We are every moment seeing the phenomena of migrations effected by means much easier to be noticed and appreciated: sometimes the winds, sometimes the waves, sometimes animals themselves, and, above all, the hand of man, are charged to operate the diffusion of forms all over the earth. I should like to remind you of the charming and ingenious discoveries which this study has made known—how a bird, an insect, on their wings, or between their claws, or in their bowels, often carry the seed which is to cover a whole country; how oceanic or atmospheric currents propel seeds to one point or another; how man himself, sometimes involuntarily, sometimes carelessly, without his knowing and in spite of himself, is the instrument of these providential transportations. Thus, after the universal exposition of the products of human industry, there were found scolytes (colocopterous insects), which heretofore had only been found in India and other distant countries. They could only have been transported along with the merchandise sent to that exposition. But such references, however pleasing to the mind, would lead me too far. Besides, one of our learned colleagues—M. Aristide Dupuis—has already in this place made the thousand means of transport which nature makes use of for the propagation of animal and vegetable species the subject of a special and most interesting lecture, which you will find in the eighth volume of our "Bulletins." You will in it see how there naturally exists between all the countries of the earth, sometimes free and open, sometimes insensible and latent, a free, natural exchange of all their productions—an admirable model of what we nowadays wish to imitate for our artificial productions.

Conceive this free exchange aiding all these means of transport, and many others yet to be discovered, acting incessantly every instant (for such is the action of the winds and the ocean currents), and during tens and hundreds of thousands of years. In conjunction with the different modifying powers of climate and other things, is not this sufficient to explain the mode in which the earth has been peopled?

It is enough for me to have given a very succinct general statement of these facts in order to prove the text which I proposed to develop before you to-day, and which is summed up in this grand proposition, that all is acclimatization, and that by acclimatization the earth has been peopled with all animal and vegetable species.

Whatever, then, the objections with which we may be met, be persuaded that you are proceeding in harmony with nature, with tradition, with science; but let us in everything imitate this great and wise nature. She does not accomplish her acclimatizations in a few days or years: she only proceeds with slow and short steps. She requires the duration of ages and the extent of space! She does not stop and repose after only a few trials:

she often begins anew. She never is weary of recommencing her work, and of correcting and recorrecting it incessantly! Before stopping at the specimens which she offers to us to-day, which are not those of yesterday, and will not be those of to-morrow, she has drawn from them many others! She has never said her last word—she is never done with her transformations! Our task is not ended; we ought not to remain immovable in the only forms which we possess. Virgil, a great poet of the earth, has told us the secret of this procedure—

Pater ipse colendi
Haud facilem esse viam voluit.

God has willed that the field open to human activity shall not be easily traversed. Let us be patient, let us be persevering, like nature! This is the price of success. Let us advance towards our end, resolutely, without distraction or distrust, sustained by this thought, that we are engaged in a great work, and that the co-operation of the humblest among us may produce the greatest results! Sowell has the Acclimatization Society understood this truth, that it, as it were, throws its doors open, and requires not the slightest proof of capacity in those who wish to unite their efforts with it; one need not to be either king, prince, or academician, in order to acclimatize a plant or an animal. The smallest such conquest is of more worth than that of a great province, and two or three such acquisitions associated with the memory of the Society of Acclimatization shall one day cause your modest labours to be blessed. Natural history, after being for long, in general, a mere science of observation, should now tend to become a science of experiment, M. Decaisne has remarked. The Garden of Acclimatization is but one realization of this idea.—*Journal of Agriculture.*

TAYLOR AND LAFFERTY'S BROOM-HEAD.

Metallic heads by which the broom-corn can be attached to the handle are coming into common use. They are economical, although costing somewhat more in the first instance than the common brooms, because the handle and head need not be thrown aside as soon as the corn is worn to stubs, but by a simple replacement of the comparatively cheap fibre the worn-out implement becomes again a broom.

The head in the engraving is of sheet metal, fastened at the top to a block through which is a hole for the reception of the handle. The handle tapers to the end, which is received in the socket of the yoke, through which pass two screws on each side of the handle, having on the outside of the case two metal braces for stiffening the box. The broom is introduced into the head, the butts being placed on each side of the central bar or yoke, until the head is filled, while the screws are slacked. These are then screwed up, and by compression hold the broom very securely. It makes a light and handy implement.—*Scientific American.*

RENOVATION OF MUSHROOM-BEDS.

In a notice of the gardens at Belyoir Castle, we find, among other practically useful and interesting matter, allusion made to the appliances and mode of growing mushrooms adopted by Mr. Ingram in that princely establishment. It appears they are in great demand there, and largely grown in back sheds. There is nothing particular in the material used for the beds, as it consists "mostly of horse-droppings, mixed with straw collected from the covered exercise house and the stable." The beds are formed about the usual depth on the floor, against the back wall of the sheds. So far there is nothing unusual; there is, however, in the economical application of heat, the mode of husbanding it, and at the same time dispensing with the covering of hay or other litter, the use of which we regard as objectionable for more reasons than one. The writer says, "Along the front of the beds a sunk flue is carried, which economises the heat that would otherwise be discharged through the chimney. The beds are covered with wooden shutters that proceed from the back wall, and rest either upon a wall or slab of wood beyond the flue. This simple arrangement ensures sufficient warmth, and obviates the necessity of any other covering for the beds." We presume, of course, though the writer of the notice does not say so, that the shutters do not rest upon the surface of the bed, but that there is an interspace enclosing a stratum of warm air. Heavy crops are quickly and abundantly produced; but, as the writer of the notice well observes, "up to this point there is excellent but not exceptional culture." It is to what follows we would especially direct the attention of our readers. As soon as the beds begin to fail or give up producing, Mr. Ingram's mode of renovating them, and restoring fertility, is out of the common track, and, what is more, appears to be eminently successful, and worthy of being more generally adopted. Here it is: "The beds are allowed to become rather dry, and are then stimulated to fresh production by the following treatment: 'They are thoroughly watered with strong manure-water, made from horse or cow droppings, and into every four-gallon can of the water a good handful of common salt is thrown, and well stirred into and dissolved in the water, and applied with it.'" We are then told "the mushrooms spring up as if by magic, and the same beds are renewed several times in this manner." The writer further emphatically adds, "Nothing could exceed the productiveness of the bed that was in bearing at the time

of my visit, which I understood was producing its third crop." Mr. Ingram, besides being one of the most eminently practical and successful, is also one of the most scientific gardeners of the day, and we have no doubt science will endorse his practice, which in this instance has been attended with results so satisfactory; his experience, now of some years, has stamped it as being invariably successful.

As pointing to the scientific solution, we may observe that it is said French growers use with advantage in the growth of mushrooms a very weak solution of another salt—nitrate of potash, or, in other words, common saltpetre. Mr. Ingram has tried the latter, but it appears without much advantage. Some six or seven years ago, M. Chevreul brought under the notice of the Paris Academy of Sciences a new mode of producing spawn, by treating the spores with a solution of saltpetre, and afterwards expediting and increasing the growth of mushrooms by the application of a similar solution to the beds, made up mostly of calcareous matter. Durochet's experiment also appears to point somewhat in this direction, and shows that fungoid growths are promoted by similar agency. He formed a weak albuminous solution, and rendering it acid, the result was the growth of various species of beaded moulds. If rendered slightly alkaline, the genus Botrytis, to which the now too familiar form of the potato mould, *B. infestans*, belongs, was produced; if the solution, on the other hand, was left in a simple state, no form of fungi appeared.

We should have added above that Mr. Ingram not only regards with favour the use of salt, by reason of its promoting the fertility of the beds, but, further, as improving the quality of the produce. He further finds it of advantage in promoting the growth of mushrooms in pastures that produce them.—*Irish Farmer's Gazette.*

LESCHENAULTIA FORMOSA.

It is an inexplicable fact, but nevertheless true, that at the great International Horticultural Exhibition only one plant of this little gem was shown. Twenty years ago, to see it glinting out in the most conspicuous position in every miscellaneous collection of stove and greenhouse was not an uncommon thing, and the superb manner in which John Green, William Hunt, and others used to colour it, and at the same time retain a sparkling crispness upon the flowers, was quite enchanting. The finished and peculiar manner in which some plants, I might almost say all plants, are brought out upon the day of exhibition, constitutes a chief, if not the chief, part of their charms. It is astonishing how one man will bring a plant or a set of plants out to the day; while another, with the same number and varieties, will have some over—past their best—others in tolerable perfection, and the remainder not nearly in bloom. The possession of this knowledge constitutes what is considered tact in plant management, and can only be attained by studious observation and attention, carried over a series of years. As a rule, it is always better to have the plants, if not up to the exact mark, coming to perfection rather than going out of bloom. A stale plant is never pleasing to any one, as its charm is over, its day is gone; but a plant nicely sheeted with fresh flowers, and with plenty more to follow, will always please, because there is something to look forward to. The colouring, too, of flowers is quite an art. Some require full sunlight, others a subdued light, and a third comparative shade. The plant under notice, to bring the flowers to a proper colour, requires to be shaded from the midday sun; but for an hour or two in the morning, and after three o'clock on a May afternoon, it may be fully exposed with decided advantage. Then, again, it must have a nice circulation of air throughout the night if the weather is favourable; but cold draughts must be avoided. Twenty years ago we used to grow *L. formosa* and *Baxteri* for bedding in the flower garden, and very nice they looked. Then we could purchase at Pamplin's Paradise Nursery, or Fairbairn's, of Clapham, nice plants in 4-inch pots at 8s. to 9s. per dozen, and larger ones in like proportion; but now good plants can scarcely be procured at all, even at a price far beyond their value. Indeed, many of our old friends have gone out of fashion, but whether from the want of taste or the necessary knowledge of cultivation it is difficult to say.

I shall not waste space by detailing the method of propagation further than to remark, that young half-ripened shoots root freely in silver-sand under a bell-glass, in a gentle heat in the spring, and that cuttings of the same quality may be put in in August in a cold frame, the same as Heaths, and they will be nicely rooted and fit to pot off in January. For the few plants required in a gentleman's establishment it is never worth while to incur the trouble of propagation, as nice plants ought to be procurable at from 1s. to 3s. 6d. each, according to their size. For growing into specimens it is a great point to get a nice healthy start. The plants should be stiff and bushy, bright green to the extreme point of each shoot, and without any dead foliage about them. If they are not so, but on the contrary weak and lanky, avoid them, for they will never be worth the trouble of cultivation. Good plants procured, the next thing is soil, and that of suitable quality is becoming yearly more difficult to procure. That from Wrotham Heath, near Maidstone, is excellent, and at one time good peat could be had at Shirley Common, near Croydon. For quick growth the soft spongy peat is the best, but if you want the plants to stay with you, a mixture of the hard peat of Wandsworth or Winstead is desirable. Soils, however, for high class plant cultivation should be duly collected and prepared for many months before they are used, or, in other words, a stock sufficient for twelve months' consumption should be got in every autumn, and be kept exposed to the free action of sun, air, and frost for at the least six months before it is used. At the time of collecting, it is a good plan to have the peat assorted, placing the good in the best situation for aeration, and putting the other aside for secondary purposes, American clumps, &c. Some years ago, when extensively engaged in plant cultivation, I had a rough rack, like a hottle-rack, made for storing peat, upon the shelves of which it was placed in layers six to nine inches thick, and thus the air and frost had free access to it, while at the same time it was protected from rain. Before putting it upon the rack, all sand, fine earthy particles, and extraneous matter were removed, so that every ounce stored was fit for use. Messrs. Fraser, of the Lea Bridge Road, used to treat their Winstead peat in the same manner, by introducing strong stakes and pea-sticks between the layers of turfs as they were stacked up, and making the top waterproof. This may appear a very troublesome process, but where the best results are desired, and plants forming a hemisphere two to two and a half feet in diameter are wished for, it must be taken. As many persons will be unprepared with such soils, a method of extemporising a compost may be suggested, and it is this: Take the best peat you can procure, and having deprived it of all unsuitable matter, break it into pieces about the size of a walnut, and then place it in a thin layer

under glass, where it will be fully exposed to the action of the air, but at the same time be protected from damp. Thus exposed for a week or ten days, it will be materially improved; but if it is poor, as most peats from upland situations are, take about half of it, and placing it in sieves, put them in a hotbed frame, or upon a dunghill where the steam is rather strong. In this way after two or three days the peat will be much enriched by the ammonia absorbed, and when mixed with the remaining portion, and exposed to the air for a few days, will form a highly stimulating compost. Time was when the use of stimulants for hard-wooded plants was looked upon as being highly heterodox, and contrary to precedent, but it is those that leave the beaten track that make new discoveries, and fortunately for the progress of good cultivation there are many who have ventured to leave the "old groove" within the last twenty years. So far as has been recorded, it was the late T. A. Knight, Esq., who first ventured to give weak pigeon-dung-water to Heaths. He found his account in it, and others ventured to follow the lead and practice which he had inculcated. Now guano and stimulants are used extensively for hard-wooded plants, and why should they not be? If we go to nature, and examine plants in their native habitats, we find the voidings of wild birds and animals freely distributed amongst them, and as this is washed to the roots by the rains that fall, it is quite certain that even the plants of Alpine regions receive some stimulus in the form of manure. The first time I spoke of giving manure-water to a large and very select collection of Heaths, and other hard-wooded plants, the foreman in charge, an expert and enthusiastic plant-grower, looked upon me as being decidedly "daft." "I might if I liked, but he would not. The plants were doing well now, and it was the best to let well alone." However, unknown to him, I persisted. Regularly as the tank was filled I dropped into it a certain measure of "Potter's Liquid Guano," and so unconsciously he not only watered the plants regularly with weak manure-water, but the water for their daily ablution came from the same source. The progress made was most complete and satisfactory, the best plant growers in England pronouncing the collection, for its age, unsurpassable. From that time to this I have used weak guano-water in the growing season for plants of all kinds, but for the last twelve months I have, upon the recommendation of my old friend, and your correspondent, "Alpha," used "Standen's Gardeners' Friend Manure," and I think with superior results. This manure seems to have some peculiar influence upon the blooming principle of hard-wooded plants, causing them not only to set their flowers most profusely, but to open them with singular vigour and richness of colour. This remark applies particularly to Azaleas, Cborozemas, Pimeleas, Epacris, Heaths, and Zichyas.

To return to the enriched peat, the value of which we have been endeavouring to show. Take for *Leschenaultias* two parts of the soft and one part of the hard, and without breaking it unnecessarily, reduce it so that every portion will pass through a half-inch sieve. Then to each peck by measure put a quart of silver-sand, and a pint each of clean soft-burned potsherds and charcoal broken to the size of horse-beans. Mix the whole intimately together by passing it once more through the sieve, and it will be ready for use. The size of the pots must be governed by the size and health of the plants to be put into them. If they are strong and healthy those in four-inch may be removed into eight-inch, while partly grown specimens may go from six or eight inch into eleven-inch pots at once. The pots must be carefully and efficiently drained, placing some rough peat or a little sphagnum to keep the crocks clean. The plants should be watered the day prior to potting, so as to have the ball in a proper state as to moisture, as that is a most important point. Fill the pot to the necessary height with the compost, making it quite firm. Then take the plant, and turning it out of the pot, remove loose potsherds, and with a sharp pointed stick disentangle a portion of the young fibres carefully from the side of the ball, place it in position, so that the collar or base of the plant will be upon a level with the top of the pot, and fill in the soil, making it as firm as possible by the compression of the hand, but not using the usual rammer with unnecessary force. A well potted plant, the soil being in proper condition as to moisture, should be so firm that the broad part of the thumb pressed with full force upon it will not make much impression. Plants will grow faster when more lightly potted, but they rarely live so long. The pots should be new, or if not new should be washed perfectly clean, and be dry at the time of use. I like a dry pot, as carefully watched it is an index of the due percolation of moisture through the compost. After potting give the plants a gentle watering, so as to moisten the soil in contact with the disturbed roots, and then set the plants away where they are to remain. If it can be had, a brick pit is the best place for hard-wooded plants through the growing season, as the ground if sprinkled daily gives off a congenial moisture, and is at the same time cool for them to stand upon. It has another advantage—the sashes can be quickly put on or off; and on warm dewy nights, or with warm gentle showers in the daytime, I have great faith in giving the plants the advantages arising therefrom. The pit containing the *Leschenaultias* should be kept to a temperature of 50° during the growing season, and should be freely ventilated both back and front, on all favourable occasions, but the plants must not at any season be exposed to cold draughts. The routine treatment will be: ventilate freely in the morning, increasing it as the day warms; water copiously when the plants require it, but avoid dribbles. On the afternoon of warm sunny days sprinkle the ground between the plants, dew them gently over with a fine syringe a short time before the sun leaves the pit, and shut up close, but before leaving for the night give a little air at the highest point, so as to allow the steam to pass off. Stake the plants when necessary, using as few sticks as possible; remove every flower-bud directly it can be handled, and guard against insects and mildew. The greenfly is the greatest pest, but it can be removed by fumigating slightly two or three nights in succession; then place them upon their sides, and with a syringe and water wash the insects clean away. Mildew is quickly checked by sulphur dusted over the parts affected.

Manure water must not be used until the newly potted plants have filled the pots with roots, but the walls of the pit and the ground between the plants may be sprinkled once or twice a week with advantage. The plants may be kept in the pit until October, but through the winter a warm airy part of the greenhouse will be the best place for them. Plants shifted from four to eight-inch pots in early spring will, if properly managed, take eleven-inch pots in August, but it would not be advisable to shift them later than that month. *Leschenaultias* grow all through the winter, therefore they must not be exposed to cold draughts, though they require a free circulation of air at all times. The subsequent treatment of specimens will be given in another paper.—*An Old Subscriber, Midland Counties, in "Gardener's Chronicle."*

SELECT HERBACEOUS PLANTS.

If one looks for the genus *ASTER* in some botanical work giving an enumeration of the species, what a string of names is seen! There are nearly two hundred species in the genus, most of them of a weedy and monotonous type; it is the prevalence of such things as these in gardens that has driven good and bad pretty nearly out of cultivation. But among them are some really worthy of our best attention, and one of the very best is the American *Aster versicolor*, which, forming as it does low tufts of leafage well covered with rather large pink and white flowers, is in autumn a most valuable and ornamental kind that one need not fear having too much of. Then there is the Italian starwort, *A. Amellus*, also rather dwarf and very good in flower; *A. Nova Anglia*, a large late kind of rich colour; *A. elegans*, with quantities of rather small white flowers that make the branchlets hang down gracefully; *A. laevis*, *bessarabicus*, *ericoides*, and *grandiflorus*, the last-named being fine, but flowering so near Christmas that it requires to be grown and trained against a sunny wall, or the beauty of its large star-rayed flowers is lost. Others may be found, but these we know to be all good, and think it better to be rather select. So much for the Michaelmas daisies; now for the Delphiniums.

These are certainly among the richest coloured and finest things we grow. There has lately been a good deal of money spent in the embellishment of that part of Hyde Park which lies beside Rotten Row and between the corner and the end of the Serpentine. Much of it has been spent on sub-tropical plants, for which the place is too exposed, and very ghastly and poor some of them look in consequence. Walking round the park a few days since, we thought the best feature of the scene to be the shrubbery, from near the front of which peer many fine heads of a popular kind of DELPHINIUM. Many nurseries now contain good collections of these plants, and it is almost needless to enumerate the best; but *William Pützner*, *Belladonna*, *Alopecuriodes*, *Hendersoni*, *Schamyl*, and *grandiflorum* are among them.

Though widely diverse in colour and in size of individual bloom to the rich blue perennial larkspur, the gorgeously coloured PRONIES belong to the same order, and merit equal attention at our hands. All the herbaceous kinds are good and showy, but the many beautiful kinds are as yet far too scarce. They may be bought at about 18s. a dozen, and the best way is to leave the selection to a respectable nurseryman, asking for a good and varied collection.

Of the PHLOX we need hardly say a word of praise, as it speaks for itself in so many gardens and at so many flower-shows in autumn. There are scores of varieties exhibiting great beauty and great diversity of colour, and not one of them that is not worth growing. They are abundantly grown in many nurseries, and sold cheap; and here again the selection may well be left to the nurseryman, if the purchaser has not the opportunity of looking over a large collection when the plants are in flower, and selecting those he most fancies.

There is a deep rose-coloured variety of the common yarrow, *Achillea millefolia rosea*, which is well worth having in a good collection, and *Eupatorium*, *aurea*, and *tomentosa*, of the same genus, are fine showy plants, with bright golden flower-heads. Then there are the various beautiful everlasting peas, so suitable for growing over dwarf bushes, over stony places, or indeed in any position, though we do not much like to see them staked as grown against a trellis, or in some places where ordinary rough staking may be dispensed with. The white variety of the common species (*Lathyrus latifolius*) is much the best, because, from some peculiarity or other, it does not seed, and consequently the fine white blossoms are produced freely till late in the season. The small-leaved everlasting pea (*L. grandiflorus*) is a finer species still, and admirably adapted for climbing up a bower or other trellis. *L. rotundifolius* and *L. tuberosus* are somewhat smaller, but free-flowering and beautiful deeply-coloured kinds.

How could we dispense with the exquisite alpine COLUMBINE (*Aquilegia alpina*) in a selection of this sort? *A. glandulosa* and *californica* are also very fine species, quite unlike the common ones grown in borders. *Adonis vernalis*, of the same order, is also first-rate and not uncommon. With these should be enumerated the fine autumn-flowering *Anemone japonica* and its white variety, the *Christmas rose*, as a matter of course; and *Ranunculus acris plena*, the bright yellow "bachelor's button;" nor must we forget the white "fair ladies of France," so nice for cool borders; *Dielytra spectabilis*, *Coronilla varia*, a pretty pinkish lilac species; *Galga officinalis*, its variety *alba*, and *Orobis vernus*, which is indeed indispensable to either spring or summer flowering selections.

It is impossible to have a really effective lot of hardy plants without some of the better IRISES among them, and among the most suitable kinds are many nicely painted varieties of the common "*Germanica*," particularly one called "*Victorine*." With it we should consider *De Bergii*, *Florentina*, *variegata*, *ochroleuca*, *amæna*, *Jacquesiana*, and *florescens* indispensable. The splendid red-spiked TRITOMAS have not yet been named; they are perhaps the most valuable of hardy herbs, flowering as they do so grandly in the autumn when other things are beginning to fade. *T. glaucescens*, or *Burchelli*, *grandis*, and *uvaria*, should be secured; the last is the least desirable, though fine. Even more brilliant than these are the early summer flowering POPPIES, *Papaver bracteatum* and *orientale*, of which we saw a splendid line at Trentham lately. They are rather coarse, it is true, but merit a place in the background. In the north and west, and moist districts generally, the lemon-coloured *Papaver alpinum* and *nudicaule* might be grown to advantage. A British plant called *Trollius europæus*, which grows in the north, is well worthy of culture in gardens, and even better and larger than this is *T. napellifolius*. The old double yellow and dark wallflowers must not be forgotten, nor the very pretty *American Cowslip* in its varieties, nor the *English Fritillary*, which grows so plentifully in the meadows in some parts of England; its white and light coloured forms are very pretty.

The CAMPANULAS we have not yet touched upon: they are in the front rank of hardy plants, and most easy to cultivate. *Carpatica* and *persicifolia*, and their white varieties, *grandis*, *maorantia*, *rotundifolia*, and that old favourite *pyramidalis*, are the most ornamental, though others of merit are likely to be met with. With these may be named *Stenactis speciosus* (a beautiful composite plant sometimes called *Erigeron*), and the old double rocket, yet plentiful in many old country gardens. *Spiræa japonica*, which, though valuable as a hardy subject, is yet more so for taking up and forcing in pots; *Potentillas*, in fine variety; *Veroniceas*, particularly *corymbosa* and *amethystina*; *Trudescantia virginica*, *Lythrum roseum superbum*, *Armorica cephalotes*, *Eryngium amethystinum*, *Symphytum caucasicum*, and *Pentstemon gentianoides* and *procerus*, are all good. Such is our

concise selection from thousands. Well we know that there are many others of merit, but those who begin with this lot, or as many as they can get of them, will not be disappointed, and moreover, after growing these, will be good judges of what is worth adding.

To cultivate them it is not necessary to interfere with that portion of the grounds devoted to summer decoration. If a border does not already exist where it is desired to cultivate them, it may easily be made, and it cannot be too deep and well made—the soil a free open sandy one, as near as may be convenient. Not a few may be suited with a good position among the shrubs, particularly those kinds that are apt to run wild in the gardens. For instance, there is a fine native plant, *Epilobium angustifolium*, as good as any we have named, but it is too wild for the garden, therefore it should be allowed to run about in a shrubbery, as it may be seen among bushes behind the late Sir Joseph Paxton's house at Chatsworth.—*The Field*.

GARDEN EDGINGS.

We are able to recommend a capital permanent edging—everlasting, in fact, and with nothing that could offend the most critical taste. This is simply made of rustic rods of cast iron, in imitation of the little edgings of bent branches that everybody must have seen. They are evidently cast from the model of a bent branchlet, about as thick as the thumb, and forming nearly a semicircle of about 15 inches in diameter. The marks where the twigs are supposed to have been cut off are visible, and altogether the thing looks as rustic as could be desired, is firm as a rock when placed in position, and, in a word, perfect. These irons are, of course, stuck in the ground firmly, and cross each other just as the stick edgings do. But, while prettier than any stick edging ever seen, they are, when fastened, also the most firm and permanent of all. They may be set up by any boy. The fact that they are not stiff and ugly brick-like bodies prevents their offending the eye if one or two should fall out of place here and there. But this is impossible; for at the place where every two sticks cross each other they are tied by a little bit of common wire, fastened firmly by a pincers, of course. They should be so plunged in the walk, or by the side of the walk, that about 7 inches of the little fence appears above ground. This, however, may be varied with the size of the subjects which they are used to encompass; 6 or 7 inches is the height given for edges for ordinary purposes. They are equally useful for the park, pleasure-ground, or kitchen garden. In parks and pleasure-grounds, however, we usually have edgings of grass—the best of all edgings—and therefore it may occur to the reader that they are useless therein; but the little fences of bent wood which furnished the idea for these iron edgings were generally used to prevent grass near much-frequented spots from being trodden upon; and, of course, those now recommended will answer the purpose better. But it is in the kitchen-garden that their chief merit will be found, while in the public garden or park they will prove indispensable in many parts. Though at present there is no such thing used in English gardens, we hope to see them shortly introduced, and, in fact, are sure they must eventually prove the most admired of all edgings.

But it is not these alone that are preferable to the vitrified and other bodies sold as garden edgings. For the kitchen garden an edging of rustic stones, flints, &c., is far better; because, from their irregularity, it is not necessary to have them precisely arranged; they have all the advantages of the artificial stone edgings, and are in many places the cheapest of all. Weeds will grow among them, of course, and may require a little more time to eradicate than in a perfectly straight edging; but this is no objection worth mentioning. We have seen large, flat, sea-worn pebbles used with great success for this purpose in Devonshire. Even common bricks, set one after another at an angle of 45°, are better than the cast edging. As for the flower garden, if we can avoid edgings altogether by having all our beds set in the turf, so much the better. But then everybody cannot do this; and, besides, we have the geometrical garden and not a few other instances to deal with in which edgings may be desirable. The old and popular edging of box is, after all, the best for such places. What have we so pretty among edgings, even of flowers, as its neat and vividly green little hedge when well kept? Nothing; nor are we likely to have. The dwarfest kind, clipped at the right time, in spring and September, if you be very particular, or once a year in spring for ordinary edgings, is the prettiest of all. Indeed, it is indispensable in the geometrical garden. But there is one other hardy green native plant, which we altogether neglect in England for this purpose, but than which nothing can be more beautiful as a wide-edging plant, especially if the garden be a geometrical one. This is the common Irish ivy. When planted pretty thickly, and kept precisely to a breadth of say 1 foot or 15 inches, it forms a dense mass of the freshest verdure, especially in early summer, and of course all through the winter, in a darker state. The best examples of this edging that we know of anywhere are around the gardens of the Louvre at Paris. They are the freshest things to look upon in that city, all through the months of May, June, and July. They form a capital setting, so to speak, for the flower borders—the best, indeed, that could be obtained; while in themselves they possess beauty sufficient to make it worth one's while to grow them for their own sakes. In some geometrical gardens we have panels edged with white stone—an artificial stone very often. These ivy edgings associate beautifully with such things, though we should add that we do not admire these costly stone edgings to panels, nor panels at all. A garden pleases in direct proportion to the variety and the life that are in it, and all these bands and circles of stone, all these unchangeable geometrical patterns, are utterly antagonistic to the true life and beauty of a garden. It should be observed that an ivy edging of the breadth of an ordinary edging is not at all so desirable as when its sheet of green is allowed to spread out to a breadth of from twelve to eighteen inches. Then its rich verdure may be seen to full advantage. It must of course be kept within straight lines, if the garden be symmetrical; if it be a natural kind of garden, you may let it have its own wild way to some extent. To fringe a clump of shrubs with it in the English garden, for instance, would answer quite as well. This is only one of the uses which the French make of the Irish ivy, as most people will remember who are at all familiar with the environs of Paris.

As to the subjects used for outer circles in flower beds, we must not say much now. There are scores of neat and pretty things which may be used in that way, and which indeed we have indicated in a former article; their number is likely to increase. But some of them may be used as permanent edgings in lieu of box, and of these the best we know is *Gentiana acaulis*, with noble blue flowers; *Iberis saxatilis*, the very hardy white rock plant,

capital for edging clumps of choice shrubs; and *Armeria vulgaris rosea* or *rubra*. This is a charming bright rose variety of the common thrift, and a capital thing to make edgings in the kitchen garden; the pale-coloured common one is of no use compared to it. The mass of rose it furnishes in early spring is something surprising. It will be found to spread out so much, however, that after a few years it will be necessary to take it up and make a fresh plantation, which will give an opportunity of increasing the plant to any extent. The old edgings of strawberries, so often used in many kitchen gardens, are a nuisance. All edgings of plants require renovating now and then, and this is against them to some extent. Sometimes a little shrub may be used with much taste in the flower, or oftener in the pleasure garden; and in this way we know of nothing to surpass the dwarf early-flowering *Erica carnea*. It might be used with the best taste around beds of roses, or any others from which it would be desirable to remove an aspect of bareness around their margin. Some people make little hedges of oak and other trees clipped small, as in one part of the Botanic Gardens in the Regent's Park. These are always ugly and troublesome, and should be avoided above all things. It is nonsense to clip a rough-growing large tree into a diminutive hedge, while you can get small, tidy, shrub-like plants, like the *Iberis* and *Erica* above mentioned, to answer the same purpose—that of edging clumps of choice shrubs, &c. It is a much more tasteful practice to edge a clump of choice shrubs in a pleasure-garden with some neat permanent plant or plants than to leave the margin bare all round and dig it. What is the use of digging it? We say distinctly that some of the most beautiful effects ever seen in a garden may be produced by edging the various clumps of shrubs, American plants, &c., with the choice dwarf shrubs and alpine, the several species of *Iberis*, *Erica carnea*, *Lithospermum fruticosum*, and *Aubrietia*. By using a distinct species for each bed, how fine the effect might be made, and how unlike the present monotony in the generality of flower-gardens! Consider for a moment what an exquisite effect might be produced by edging a bed of dwarf choice shrubs with *Hepatica* in mixed colours. And we could name many combinations equally beautiful made by margining permanent plantations with choice dwarf plants.—*The Field*.

THE FLOWER SERMON AT ST. JAMES'S, ALDGATE.

The church was so much crowded on Whit-Tuesday, that many persons went away unable even to obtain standing room. The text was Numbers xxiv. 6: "As the trees of lign aloes which the Lord had planted," and the sermon, by the rector, the Rev. W. M. Whittemore, D.D., was especially addressed to the young, drawing from the teachings of creation useful hints for the formation of Christian character, and urging the importance of thorough devotedness to the Lord's service. On this occasion the young people, according to their usual practice, brought bouquets of flowers, but the best flowers were themselves, with their young, bright, and eager countenances fixed on the preacher during his sermon. The singing was excellent, and much credit is due to Mr. Buckland, and his selected members of the Cathedral Evening Service Choir, for their kind and talented assistance, so freely rendered on this special occasion.—*City Press*.

Calendar.

WORK FOR WEEK COMMENCING JUNE 29.

Kitchen Garden and Frame Ground.

CUCUMBERS must have steady bottom-heat to produce fine fruit. It is a common fallacy that when the weather becomes warm the beds may be left to cool down, but it is rarely fine fruit are cut from frames that are never lined after the first heat is out. Keep a moist atmosphere, for cucumbers absorb immensely by their leaves.

LETTUCE.—This useful salad is too much neglected after the early part of the season, through the tendency of the plants to bolt in hot weather. This may be prevented by planting in a rich cool soil, and giving some amount of shade.

PEAS.—Good autumn crops may be had by sowing now such sorts as Wrinkled Marrow, Hair's Dwarf Mammoth, and Veitch's Perfection. A layer of manure should be put at the bottom of the trench, to draw the roots down, and prevent suffering by drought.

POTATOES to be frequently hoed between. A dressing of wood-ashes and guano between the rows of the main crops now will considerably increase the produce, especially on sandy or chalky soil, where disease rarely appears; on moist loams and clays it will be less safe and less necessary. As fast as crops are taken off, trench and manure for broccolis, cauliflowers, and winter greens.

LEeks to be planted out in rows nine inches apart every way, in very rich moist soil.

Sow last crop of broad beans, Walcheren broccoli, Early York and Colard cabbage, kidney beans (dwarf and runners), lettuce for succession, any early kinds of peas, radishes, and turnips. Keep the hoe in active service between advancing crops.

TREE ONIONS need a little support, as the crop is apt to fall over and be preyed upon by snails. As soon as the onions are as large as walnuts, and lock inclined to ripen, snap the stem, but do not break it through; this will assist them to ripen. The top bulbs are the best of all onions for pickling, and those at the root store well for kitchen use.

ARTICHOKES are now coming to table in plenty—that is to say, where they are grown, which is in very few places. As the heads are cut the plants must have attention; cut the stems off to the ground, remove dead leaves, fork over the soil, and lay on a heavy dressing of half-rotten dung. If wood-ashes are at command, cover the dung with a thin layer; they need not be watered, for at this season the heavens will soon supply them with plenty, and the labour may be saved.

ASPARAGUS.—Any more cutting of this crop will ruin the plantations. To many it may seem needless to make this remark, but people are cutting asparagus now, and we must advise them to desist, unless they have made up their minds to the policy of killing the goose, &c. Where the beds have not had much attention, let them be at once pointed in with a fork, all weeds raked off, and the surface covered with a mulch of half-rotten dung. Manure rotted to powder should never be used as a mulch; there is no strength in it.

BEANS to be topped as soon as they show flower, and crops ready for use to be topped back a second time to within a leaf or two of the plumpest of the small poles. Earth up advancing crops.

BROCCOLI must now be got out to furnish a supply during autumn. Manure liberally, and if the planting is done in dry weather, give water as abundantly as possible. Better, however, to get the ground ready and wait for showers, both to save labour and to give the plants a better start, for a free natural growth is especially requisite with broccolis and cauliflowers. Transplant from the seed-bed to a piece of rich light soil the plants from the late sowings. Small clubs just appearing on the roots may generally be removed with the thumb-nail, but where clubs are formidable, from the size of the plants, throw the plants aside and burn them.

CAULIFLOWER.—Plant out, and remember that for this crop the soil cannot be too rich; they will actually grow well in dung only, if well rotted. Hoe between those coming forward, but do not earth up the stems, except of such as are loose at the collar.

CELERY requires a heavy watering where the ground is dry. If the fly has attacked the leaves, pick them off and burn up; generally a few leaves only are touched, and they can be spared. But as no crop will bear to be entirely diseased, where the grub has got the upper hand it will be in vain to expect much produce. We once lost a long row of *Chenopodium atriplicis* by the grub of celery-fly, a plant we never before saw attacked; this indicates a partiality for the spinach warts, which is rather a serious matter. Dustings of soot, therefore, so useful to protect celery, may be needed also among beets and spinach.

WINTER GREENS to be planted out at every opportunity. It is most important to get out good growths of Brussels sprouts as early as possible.

Flower Garden.

Roses that have bloomed freely require to be pruned back, and have a mulch and plenty of water to assist the autumn bloom. Half ripe shoots of most of the perpetuals may be struck now, with the help of a moderate bottom-heat; but it is full early yet, and better to wait a week or two than waste time in putting in soft shoots. Buds to be entered on briars with discretion; if either the buds or the shoots to be entered on are in a soft state, they will not take; the bark must be firm, or the work cannot be done properly. One night's heavy rain will do more to perfect the stocks and scions than a week of artificial watering. Roses strike from cuttings now with great certainty. The safest way is to make a hotbed at once, and the same day put in cuttings of young wood three or four inches long singly in thumb-pots. Water the cuttings, place them in a cold frame, and shade with mats. There let them remain for a week, by which time the hotbed will be sweet, and the heat steady, and the cuttings will have formed a callus. Place them on the bed, and shut up; give air by degrees, and keep them from flagging by frequent sprinklings rather than by heavy waterings. Shoots that have just flowered, or that have flowers on them, will root with certainty.

CHRYSANTHEMUMS require liquid manure now, and frequent sprinkling overhead. Tie out as fast as the side-shoots break, for if they once harden out of shape it is no easy matter to restore them to a proper form. Plants recently struck may be planted out in a bed, where they will require less care as to watering than in pots, and may be taken up in dull weather without losing a leaf. It is not too late now to strike a few pompones to flower under glass, to make the house gay in the autumn.

FLOWER BEDS need a slight hoeing before the plants meet, and the subjects that require pegging should be kept regular betimes, and especial care to be taken to get plenty of shoots on the north side of every plant, leaving the south side to take care of itself, which it is pretty sure to do.

HARDY SHRUBS of all kinds may now be propagated by layers or cuttings, the latter preferably, and the smaller the better if the shoots are firm. Aucubas, Laurels, Laurestinus, Griselinia, Box, Ivy, Holly, &c., &c., may be increased indefinitely by putting in small cuttings of this season's growth in sandy soil, in a shady place, and keeping them watered in dry weather. Any rather tender subjects struck in this way should be potted in September to keep in frames all winter, but generally they may remain where first put in till the following spring. As Irish Ivy makes a grand edging to great beds, the hint may be useful that now is the time to propagate it for such a purpose next year.

HARDY HERBACEOUS PLANTS of all kinds may be propagated now from seeds and cuttings. See to Antirrhinums, Pansies, Mimulus, Dianthus, *Iberis coraeifolia* and *sempervirens*, *Arahis* of sorts, especially those with variegated leaves, and *Dielytras*, though these increase rapidly by parting the roots.

RHODODENDRONS.—In all cases, unless seed is wanted (and generally it is of no use), the dead trusses should be removed without injury to the young shoots. If seeds are allowed to ripen, the growth is checked, and there will be less bloom next year. As to the young growth, generally speaking, it is best to let it grow in its own way; there is no shrub so orderly in its habit as the *Rhododendron*; but where the growth in any one direction is irregular, the knife may be used now to cut it back, and it will be best to cut to the old wood in such a way that it will break and fill up any gap caused by the pruning. Water can scarcely be given in too great a quantity now to *Rhododendrons* and *Kalmias*; nevertheless in turfy peat and loam sunk below the level (they should never be above the level) it is rarely they require artificial watering. As a rule, the removal of the dead blossoms by a dexterous snap of the thumb, easily acquired by practice, is all the attention *Rhododendrons* require in the open air; but we are supposing them to be in beds of good peat, or peat and loam chopped up together: if they are in what is called "common garden soil," or stiff clay, it will be a trouble to keep them alive. Old beds may be refreshed by a top-dressing of cow-dung. It should be remembered that American plants thrive best when they get rather thick, as then the roots are screened from the sun. *Rhododendrons* in pots mostly want a shift now, but it must always be a small one, as too great a shift will be likely to cause the bloom buds to start prematurely, which will result, not in a second bloom, but in a crop of leaves, to the loss of bloom next year.

HARDY PLANTS IN FLOWER.—*Viola cornuta* and *lutea*; *Oenothera Fraseri*, *Lamackiana*, *speciosa*, *riparia*, *serotina*, and others; *Symphitum asperinum* and *Kermesina*; *Armeria formosa*, *Platycodon grandiflorum*, *Gypsophila Steveni*, *Chelone barbata*, *Verhascum lagurus*, *Alstræmeria aurea*, *Phyteuma Hispanica*, *Campanula gargarica*, *carpatica*, *rotundifolia*, and others; *Sanguisorba Canadensis*, *Lythrum roseum superbum*, *Arenaria cæspitosa*, *Myosotis alpestris*, *Morina longifolia*, *Gentiana cruciata*, *Achillea ptarmica*, *Malva Moreni*, *Helenium pumilum*, *Papaver alpinum*, *Epilobium angustifolium*, *strictum*, *Saponaria cæspitosa*, *Hedysarum splendens*.

Fruit Garden and Orchard House.

FRUIT GARDEN.—Put netting over currants, gooseberries, and cherries, to keep the birds from the fruit. To retard or keep hanging currants and gooseberries, cover with mats. Strawberry runners to be pegged down in pots, and the superfluous runners to be cut away an inch or two from the stools.

STRAWBERRIES, as soon as rooted in pots, to be removed to a frame and placed upon a bed of some moist material, where they will soon fill the pots with roots. Remove weak runners, and peg down in pots or on the border a few more of the best.

RASPBERRIES to have their suckers reduced to three or four to every stool; those left will rise strong, and ripen their wood well, but a forest of spray will be all weak alike and at the winter pruning there will be a temptation to leave all, because for strength there will be little choice. Never dig between raspberries; it causes them to throw their suckers a long way from the stools; but surface manurings at this time of year, and no disturbance of the earth, causes strong suckers to rise near home.

VINES AND VINE BORDERS.—If there is a good wall, a lean-to may soon be put up, and there may be a border outside, and the vines brought in and trained to the rafters. Under the vines a few orchids may be grown. Better still, ferns, as the vines will give them shade just when they require it. But to keep bedding plants or to flower pelargoniums, and other plants that need plenty of light, is a great folly. In fact, wherever it is attempted to mix greenhouse plants with vines, there must be more or less injury done to one or the other; they cannot both prosper in the same house. We depend chiefly on sun-heat, but a little help from hot-water pipes, if heating can be afforded, is an advantage. The Paxtonian houses answer admirably for vines, and if you have choice of wall, and can put up a house ten or twelve feet high, a sixteen or eighteen feet rafter will be the proper thing. The width of the border must be proportioned to the length of the rafter, say for a ten feet rafter a border full in the sun (the house should face south) four feet wide; for a fourteen feet rafter, five or six feet wide. The Paxtonian house can be ordered to measure, and the lights and irons will be sent ready for fixing, with directions, so that the village carpenter can put it together in a brief space of time. If cheapness and efficiency are aimed at, without regard to ornament, a low span-roofed house will be found admirable, and the following measurements will suit most people: Sixteen feet wide; brick walls three feet high; height to ridge, eight feet. A border on each side four feet wide would leave an eight feet space in the centre. To economize that space would be an easy matter. If ornament were desired, it would answer to have one row of large specimen fuchsias in pots standing on clean gravel or concrete, and leave the rest of the space for walking. A few ferns might be accommodated with the fuchsias, and there would be no litter, no crowding, sufficient walking space for enjoyment; and the same treatment would serve for all. As for the construction, it may be borne in mind that vines do not need much air. Therefore apertures in the wall a yard apart, seven to nine inches square, and at each end of the house, over the door, a triangular shutter fitting closely to the angles of the ridge, will suffice. Such a house ought to be heated with a small boiler at one end, and two courses of four-inch pipe all round. As we have no intention to force, the fire would not often need to be lighted. But in case of cold, damp weather, when the vines were in flower, a moderate heat, at the cost of a few bushels of coke, would make sure of the crop. So again, in case of a cold wet summer, with the benefit of a little heat to ripen them, good colour and flavour would be ensured. A still cheaper method of procedure would be to make the border outside, and dispense with heating apparatus; but this plan would be occasionally attended with the drawback of a poor crop. With the border inside and with command of artificial heat, you may be sure of grapes every season; with no heat, and with outside borders, you would not get a berry in such a season as 1866 was. Outside borders answer better with lean-to houses, because we can have them facing full south; but a span-roofed house must be put to run as nearly as possible north and south, so as to get the sun on all parts of the house during the day. The borders, therefore, face east and west, and have much less sun-heat than when a south-looking lean-to has a border sloping full in the face of bright Phoebus. The borders would require to be thoroughly well drained to begin with. The stuff for the border should consist in the main of good turfy loam, with a very plentiful admixture of sandy road drift, broken oyster-shells, broken bones, and clean lime rubbish. After many years' cropping the vines begin to need a little help, and then a good mule-heap with fat dung will produce its effect. One of the most prevalent errors in vine-growing is the free use of manure; nearly all the shanking, rust, mildew, and the rest of the plagues are produced by manure; and when all works well, manure only makes large berries, it does not make either flavour or colour. Reserve the fattening foods, then, for times of real need; for the first start and for many years to come, turfy loam, siliceous and calcareous additions, will make fine canes, and superbly coloured and flavoured grapes.

Greenhouse and Conservatory.

GREENHOUSE HERBACEOUS PLANTS, such as Cinerarias, Primulas, Heliotropes, herbaceous Calceolarias, &c., must have frequent attention now. Get seedlings pricked out into pans or singly in thumb-pots; shift cuttings and rooted suckers; sow Calceolaria and Cineraria to succeed the first lot; a moist, cool, shady place will bring them on, and as they gain substance they must have more light and air. Use for all these plants a light rich compost, in a sweet and friable condition.

CONSERVATORY will require air night and day, unless there are many stove plants, in which case shut up while the sun is on the house. Use water in plenty, and liquid manure wherever it seems to be required. Free-growing soft-wooded plants may be assisted now by placing the pots in pans of water, and sprinkling the paths morning and evening.

WINTER FLOWERS must be thought of now. Propagate Euphorbia Bojeri, Jacquiniiflora, and splendens; repot and propagate Poinsettia pulcherrima; give Salvia splendens another shift; set out in the open air Solanum capsicastrum, and Calliandra purpurea; put all potted shrubs for winter blooming in a cool moist bottom for a month, then remove them to a sunny position under a wall or fence, to hasten the ripening of the wood.

HARD-WOODED PLANTS mostly require shifting, if only to remove a little of the worn-out stuff on the outside of the balls, and repot them in the same pots. The soil should be lumpy, and with plenty of fibre in it. Take care the drainage is safe; a strong oyster-shell over the whole is a safe way to ensure an outlet for water. After shifting, sprinkle frequently, and give only a little water to the roots.

GREENHOUSE PLANTS IN FLOWER.—Zonale and large-flowered pelargoniums, globe amaranths, cockscombs, balsams, herbaceous calceolarias, and fuchsias, are now in their prime; also Bossia inophylla, microphylla, and scolopendrium; Septas umbella, Abronia mellifera, Senecio elegans, and cinerarioides; Nymphæa bivalvata, Acemadina tetragonia, Nivenia spatulata, and Lagopus; Mirbelia dilatata, Acronychia Cunninghamii, Adenandra fragrans, Adesmia viscosa, Actinotus helianthus, Mimulus roseus, Sempervivum arborescens, caespitosum, and tortuosum.—*Ericas*: Ilibertiana, Albida incana, Blandfordiana, conspicua, depressa, exurgens, fastigiata, inflata, Juliana, Monsoniana, palustris, Parmentieriana rosea, pulverulenta, Sainsburyana, speciosa, splendens, Humea, Ventricosa hirsuta, tumida, varia, jasminiflora rubra, gemmifera, thymifolia.

Stove and Orchid House.

ORCHIDS require now a free circulation of air to ripen the spring growth. Use as little shading as possible, and keep the air moist by watering the paths and borders in the afternoon, after which shut up.

ORCHIDS IN FLOWER.—Epidendrum alatum majus, E. maculatum grandiflorum, E. phoeniceum, E. verrucosum, Calanthe masuca grandiflora, Aerides affine, A. quinquevulvum, Acineta Barkerii, Dendrobium filiforme, Mormodes citrinum, M. luxatum, Angreum caudatum, Anguloa Clowesii macrantha, Bolbophyllum Henshalli, Warcea tricolor, Vanda tricolor, Stanhopea aurea, S. Devonensis, Cattleya amabilis, C. candida and superba, C. crispa, crispa superba, C. labiata picta, C. M'Orlandii, &c., C. Schilleriana, violacea, Dendrobium alba sanguineum, D. sanguinolentum, D. taurinum and formosum, Cœlygne Lowii, Cycloches barbatum, Oncidium divaricatum, O. papilio majus, &c.

Forcing Pit.

PINES to be encouraged with heat and moisture. Young stock to be aired freely, to get them strong; fruiting plants to be refreshed by frequent sprinkling of the beds and plunging material; as they begin to ripen, keep them drier. As soon as fruit is cut, earth up the stools and give extra heat. Plants now coming into fruit to be pushed on so as to ripen at the end of September and beginning of October, when the summer fruits are scarce.

VINES in early houses to be kept rather dry, to promote the ripening of the wood, and to have plenty of air. In late houses encourage quick ripening, keeping up the heat, and ventilate well to prevent damp and mildew. Water and mulch the borders of late houses, and by all means abstain from cropping the borders, as the practice is most injurious to the roots of the vines, the best of which are near the surface.

Correspondence.

PARIS EXHIBITION.—I conclude from the interesting papers you give us from your Paris correspondent that gardeners would do well to visit the Exhibition. Now how are they to do it? You will say take tickets by South-Eastern or Great Eastern or some other railway, and trust themselves to the elements. I think if the employers of some faithful and able gardeners were to give them leave and a bonus to help them across, it would be a generosity well bestowed, for they will assuredly learn something that will be a benefit to the gardens they have to keep. I throw this out as a hint only. I do not want it myself, having better wages than many worthy brothers of the craft, too many of whom are under-paid. Yes, sir, under-paid I say, and yet expected to learn while they live, and look respectable too. But how delightful it would be if a company of gardeners—say any number, from a score to a thousand—were to go in a party, and have a guiding genius amongst them who understands the French language and knows all about the interesting points of the affair, and who would direct them to save them the inevitable loss of time pottering about amongst things they would neither understand nor care about. You know, it's a sort of delusion for a man who wants to see some of the French training of fruit-trees to lose himself in a court filled with samples of lace or tin-ware, or to go in the wrong direction through the kind advice of some Frenchman who has misunderstood the question put to him. But, besides all that, the feeling of brotherhood that prevails amongst the craft should, I think, be fostered on such an occasion as this, and there is nothing like a *strange place* to make men who have some taste in common fraternize and cultivate a regard for each other and a consideration of mutual interests. I wish some one would seriously propose a gardeners' excursion some time in July, and that all the details of expense of travel could be settled beforehand, so that all could go at the same price and in the same train and vessel. But I would leave them to so much freedom that I would not make a close programme of proceedings. Say the trip to occupy a week, and two days out of the week to be devoted to visiting certain parts of the exhibition, and the party to be a committee on its own account for comparison and criticism; for as two heads are better than one, so two or three hundred heads might constitute a horticultural wisdom useful to our business as we follow it at home. To say that a social gathering to wind up with before starting away for home again would be desirable and agreeable, if properly carried out, seems scarcely needful; yet if I go—as I hope to—I should hardly like to leave without spending a few hours in social enjoyment with a few of my cotemporaries. I submit these proposals, Mr. Editor, to all whom it may concern, and sign myself, as my desire is to be on the wing, A HORTICULTURAL SWALLOW.

THE SEASON.—I have to thank you for your remarks on the season and the crops; for they have not only given me the comfort that results from knowing we are not alone in our misfortunes, but they satisfied my worthy employer that we were not all to blame in our garden work for the scarcity of vegetables and flowers for some months past. In this district (near Nottingham), we had till within the past ten days almost given up all hope of obtaining anything from the ground after all our labour. Potatoes planted early have not yet afforded a single tuber large enough to cook, and many people are digging them up and tossing the haulm on the muck-heap to plant winter greens or sow turnips. Parsnips and carrots failed in all the early sowings, but some sown in May are actually alive and promise now to do well. We lost all our early breadths of French beans, as you report to have been the case in the northern suburbs of London, and seeds generally appear to be bad this season, though perhaps the exceeding coldness of the ground was much more the cause of the general failure than the inherent badness of the stuff. It is in such untoward seasons as this that we hear complaints mostly of bad seeds; one

cannot help thinking that the same seeds would be found as full of life as the best sample ever sown if favoured with a sufficient temperature. I am happy in being enabled to inform you that during the past eight days an immense difference has taken place in the appearance of the crops, and yet a bleak east wind has been blowing and the nights have been almost frosty. I attribute the renewed vigour of vegetation to the intensity of the sunshine, and I fancy from what I have read that our climate this year approximates very closely to that of the northern parts of Scandinavia; for we know that the Swedes, Danes, and Finns grow the same sorts of vegetables that we do to perfection, though they sow their seeds a full month or more later than we do, but have more sunlight than us to make up for it. In my few journeys northward—never farther than Inverness—I have noticed that the sunlight is purer and the air bleaker than in mid-England, and vegetation, though less luxuriant, is nevertheless vigorous and more active in growth, no doubt in great part the result of the augmented power of the actinic principle of the sun's rays.

W. H. B.

SENDING FLOWERS BY POST.

Correspondents who send flowers for our opinion are greatly disappointed when they learn that "your flowers were dried up when they came to hand, and we can offer no opinion of their merits," yet such is a quite common occurrence, and one of the wonders of editorial experience. For it is a wonder, to say the least of it, that men who grow flowers, and who know much about them beyond what may be seen and learnt in the garden, should expect them to travel safely when merely wrapped in dry paper or put loosely into chip boxes, and then committed to the post at this time of year. As an experiment in hay-making, this mode of transmitting bits of vegetation may be all very well; but that is not the intention; the senders of the desiccated scraps wish us to see them as they see them, fresh and bright, that we may say whether in our judgment they are good, bad, or what else. Now, let any of these disappointed correspondents consider for a few moments one aspect of the subject. Suppose the flowers on which our opinion is desired are now growing at York, A, B, or C, the grower thereof, purposes to forward them to us. He cuts them perhaps in the morning, when they are at their best, puts them loosely into a chip or pasteboard box of some sort, taken haphazard from a drawer or closet. He seals up the box, and directs it to Aldersgate Street, and perhaps he attaches a proper number of stamps. We say "perhaps" here advisedly, because sometimes we have to pay sixpence, eightpence, or more for these packages, and in every case of that kind we fling them away as far off as possible, and know nothing more of them; time is too precious to be wasted in asking people to refund what we have been mulcted of, and experience has taught us to deal in a summary way with every species of humbug and annoyance. But suppose they are delivered free (as we are bound to admit is the case generally speaking), they are as a rule twenty-four hours old when they are received at the office. The next thing to be done is to send them on to Stoke Newington, and there may be a little delay even to the extent of half a day or so between the receipt and the dispatch of the flowers at Aldersgate Street. We will now allow three hours to elapse ere they are delivered at Stoke Newington, whether by post or carrier, and we may consider another day to have elapsed ere we see them, or say from thirty-six to forty-eight hours from the time the flowers were cut. But here another delay is possible. Editors occasionally leave home; not often, it is true, for they are such a poor set they seldom have boots fit for walking in, and riding is out of the question, and another whole day or so may pass just at that particular juncture when A, B, or C's flowers, already worn out by travel, are seen by the person to whom they are addressed. Here is the case as we are familiar with it, make what you please of it, friends. This is not the first or second time we have endeavoured to make the path easy for cultivators to obtain our opinions on their flowers, and having shown how the case commonly fails, we will proceed to remark on the conditions of success. At this point we are reminded of a great lot of herbaceous calceolarias of "Neill's Strain" on which we reported three weeks since. Those flowers came from the extreme north of England and were subjected to several small delays, yet when we opened the package they were as fresh and as bright as if just gathered, and we were enabled to place all the bunches in vessels filled with water, and have a good leisurely look at them ere saying a word as to their qualities. The fact is, they were skilfully packed in a close fitting square tin box, one foot deep and fifteen inches square, the lid of which fitted accurately. Within this was a sort of wooden cage formed of very thin laths, say half an inch wide and an eighth of an inch thick, and which was lifted out bodily. Within this cage the flowers were packed in bunches, every bunch being surrounded at the base with moss, and all of them bedded in a mass of moss at the bottom of the cage. The moss was moist, the tin box almost air-tight, and the flowers came out almost as fresh as when they went in, though nearly forty-eight hours had elapsed from the time they were gathered till the time we saw them. We remember a similar case occurring about this time last year. Messrs. Barr and Sugden desired us to see a collection of *Ixia*s grown by one of their agents in Jersey, and they were sent from Jersey direct, and we had them in a state of perfection. The bunches were tied round with moss at the base, and were laid one upon the other with a little damp moss sprinkled between them in a long deal box, and above them a few cross-bars of wood were fixed with nails, so that in the event of the box being turned upside down, or even thrown from hand to hand by the carriers, the flowers were so fixed by the cross-bars that not one could move, and therefore no ordinary concussion could harm them. An occasional correspondent, Mr. Alexander Boyle, of Narberth Pembrokeshire, sends us leaves and flowers, and sometimes cuttings of plants, simply folded in oiled paper and enclosed in common envelopes, and they generally arrive in a condition not only such as admits of fair judging, but we can strike the shoots if desirable, and we have, in fact, several plants obtained from cuttings sent in this simple way. The grand thing is to arrest evaporation; this the damp moss accomplishes in one case and the oiled paper in the other. Common tin-foil is also an excellent preservative of leaves and flowers sent by post.

In the case of subjects that cannot be submitted to pressure, a box of some kind is essential. The Post-Office authorities properly refuse to carry boxes with sharp edges, and any tinman will quickly make a box of any size, for a mere trifle, with the edges rounded, so that the Post-Office regulations need not be infringed. But wooden boxes, even if of the most fragile kind, will usually answer the purpose, if the flowers are packed in it tight enough and sufficiently fixed to prevent injury by shaking, yet loose enough that they do not injure each other by pressure, with a slight amount of moisture to keep them fresh; but in no case should they be wet, or that may cause as much mischief as extreme dryness.

A common error in packing flowers for the post is to bed them in masses of dry cotton-wool. We do sometimes receive good samples packed in that way, but commonly the juices are drawn from them by the cotton-wool, and they come to hand shapeless, shrivelled, and indeterminate. It is not always possible to obtain tin boxes and other specially prepared receptacles, and the boxes that seedlitz powders are sold in, the wooden boxes, two or three inches over, in which tooth-powders are sold, and the small wooden barrels, about four inches high and two or three inches diameter, in which many housewives keep such things as arrow-root, and in which some grocers pack coffee and spices for sale, are severally suitable, and in most houses are ready to hand. Card and paper boxes are generally not so trustworthy as wood or tin, on account of their liability to be crushed, and the excessive evaporation of moisture from their contents they allow. Given a suitable box, the rest is very easy. A little damp moss will be found the best of packing, and if the flowers are firmly bedded in it, they will continue fresh for two or three days. Not long since, we sent a boxful of flowers a long journey to a friend. They were packed in a long deal box—a sort of fig-box—with clippings of privet above and below, and the flowers carefully laid together, without ties, but as it were in a heap, the small clippings of privet serving to fill up, and keep them from being shaken on the journey. They reached the friend in a perfectly fresh condition, though the journey comprised three separate changes from rail to rail, and from rail to carrier's cart. Freshly gathered ivy-leaves, and even fresh grass-mowings, answer admirably, without any addition of water; in fact, fresh green leaves of any kind will do, and if bruised, as in the case of clippings of privet or mowings of grass, the better. Lastly, these perishable things may always be forwarded to us direct, as we have frequently suggested. If directed to Stoke Newington, London, N., they will probably be in our hands a day earlier than if sent to the office, and the best days for our convenience to receive them are Tuesdays and Wednesdays; therefore, as a rule, Monday is the best day on which to post them.

S. H.

HOW TO TAKE IMPRESSIONS OF PLANTS.

The advantage of being able to take accurate impressions of plants without much labour need not be pointed out to those who can appreciate what is useful. It is not brought forward as a substitution for dried specimens, where these can be obtained and attended to; but as being less cumbersome it deserves notice, as a means of refreshing the memory, in very many instances, in a manner equally satisfactory as when specimens are employed. It has, further than this, no claim to novelty, but simply to usefulness.

The materials required are few, and these not expensive. One pennyworth of lampblack and one pennyworth of sweet oil are all that will be required besides the paper. A large sheet of paper should be provided, and this should be prepared by rubbing it evenly all over with a piece of flannel moistened with the oil; this must be done thoroughly, and when the paper is well moistened, but not in a wet state with the oil, a small quantity of lampblack should be laid evenly over it, also using flannel for this part of the operation. If this preparation can be made a day before using the paper, it will be so much the better. The next process requires great care:—Having the prepared sheet in readiness, place on it evenly and flatly the plant, flower, or leaf, of which an impression is required; then place over this a dry sheet of paper, and with a handkerchief or cloth press firmly over every part, that it may equally and regularly receive the black preparation. The paper intended to receive the impression should now be in readiness, and the specimen must be carefully removed and placed on it, and great care must be taken that its position is not changed; this, too, must be again evenly and firmly pressed as before, and the impression will be complete, and must be laid carefully aside to become dry. A specimen or two can be tried on a spare sheet, in order to ascertain whether the blackened sheet is in a proper state of preparation, before it is attempted to take a very careful impression. This is particularly valuable in preserving sketches of the leaves of rare and valuable plants.

OUR TREES AND THEIR ENEMIES.—For the past two or three seasons our trees have suffered from the attack of larvae or grubs. Amongst these enemies (after little boys) perhaps the most dangerous is the "Cossus ligni perda," the larva (grub) of the "goat moth," called thus from the rank smell, similar to that of the well known quadruped, it emits, and this so strongly at times that by it betrays the locality of its habitation. This grub is, when full grown, the size of the middle finger of an adult, of red brown colour on the back and pale salmon underneath, with a jet black shining, wedge-shaped head, with which it can lift, comparatively, enormous weights. It feeds, when young, on the albumen, between the bark and the wood of the tree, and ultimately bores labyrinthian passages through the whole trunk, causing certain ruin. Even a single insect, if it should complete its destructive course in a circular way round the stem, is capable of laying low a tree of more than fifty years' growth in two seasons. They generally begin their pernicious career at the place of their birth, mostly at the foot of the tree, close to or a little below the surface of the ground, where they easily escape observation until the attacked tree shows more apparently by its sickly looks signs of decay. This larva is of great endurance, firm against frost as well as chemists generally vaunted as vermin killers. It requires two seasons to reach its natural terms of change into chrysalis, for which purpose it burrows, during the month of October, into the mould surrounding the stem, to enshrine itself into a firm cocoon, composed of bits of wood and silken filament of its own fabric, from whence, in the spring, the goat-moth issues, in order to deposit a number of light green eggs in the crevices of the bark of elm trees in preference, but also of other trees. In order to diminish this rapacious insect, care should be taken to remove the mould surrounding the stems of affected trees, and to burn or otherwise destroy it, and to keep a vigilant eye on the nests of young larvae to dislodge them before they have eaten their way beyond reach.—VERONICA, in "Leamington Courier."

SUBSCRIBERS TO THE GARDENER'S MAGAZINE who desire to extend its sphere of usefulness, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a SPECIMEN COPY free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

Replies to Queries.

Proliferous Rose.—D. T. C.—Yours is an interesting case, as it is but seldom a tree produces a large crop of these prolific flowers, though one or two on a tree is not at all an uncommon occurrence. The flower sent (like *Boula de Nanteuil*) is of large size, and with abundance of stout petals. In the centre is a bunch of buds, six in number, giving to the flower a very singular appearance. The excessive production of these monstrous growths must in your particular instance be regarded as entertaining, but in a general way this sort of monstrosity is undesirable, and the question arises, can it be prevented? We believe the cause to be over-feeding, and have no doubt at all that the ground on which this tree stands was liberally manured last autumn, and that the roots have got hold of a body of manure that has escaped being mixed up with the soil. It is a golden rule in all cases of applying manure to blend it with the soil thoroughly, for when dug in in masses roughly irregularities of growth invariably appear in the crop, whether it be roses, cauliflowers, or what else.

Zonate Pelargoniums.—T. L. B.—The following nine Zonate varieties are first-rate for pot culture: Madlle. Vincent, white; Madame Werle, painted; Amelina Grisau, painted; Dr. Lindley, light scarlet; Andrew Marvel, deep red; Herald of Spring, flame red; Mrs. W. Paul, pale pink; Hibberd's May Queen, deep pink; Tintoret, puce rose. The following nine Tricolor-leaved varieties are also first-rate for pots: Mrs. Pollock, Jetty Lacy, Lady Cullum, Sophia Dumaresque, Titania, Sunset, Italia Unità, Lady of Shalott, Silver Star. As the foregoing list of nine tricolors includes some that are not to be had at less than from two to three guineas a plant, we offer another list of nine cheap tricolors: Mrs. Pollock, Sunset, Yellow Belt, Mrs. Benyon, Oheron, Argus, Beauty of Guestwick, Italia Unità, The Countess. See page 206 of this year's issue (May 18, 1867) for copious selections for various purposes.

India rubber Tree.—T. L.—You may remove the two deformed leaves by cutting them off close to the stem without injury to the tree. You must judge for yourself whether the tree will be injured in appearance by the loss of those leaves. The plant should have plenty of water now, and occasionally the leaves should be cleaned with a soft sponge and tepid water.

H. Tipping.—Your geraniums were all shrivelled up before they came to hand. A cardboard box will never do at this time of year for conveyance of flowers by post, especially if they are without any moist packing, as yours were. Judging by the size of the petals, we conclude that your varieties are of no value, but they may be useful as bedders.

J. E. Daniel.—An index for the numbers, May 6th to December 30th, 1865, inclusive, was published immediately after the completion of the volume, and may still be had at the usual price of a number.

J. S.—What can it matter to the horticultural public that servant-maids go to Victoria Park on Good Friday and enjoy healthy exercise and fresh air? We really do not understand the purport of your letter; if it is intended to cast a slur upon any particular religious denomination or sect, we do not want it; but if you are simply overjoyed that the poor of the East end of London know how to spend their holidays rationally, our sympathies are with you, and we will hope to see the servant-maids enjoying an innocent frolic in Victoria Park next Good Friday.

Hybrid Pelargoniums.—R. W. B. P.—How these have originated it is not easy to say in every case, and probably few of them are really hybrids, but merely crosses. A hybrid must be the result of breeding from two species, but within the limits of a species there may be any number of crosses. We have cross-bred sheep and cattle, but no one with brains enough to fill a spoon would call them hybrids. The publication of your paper would not advance the inquiry at all; the best it could do would be to raise a laugh at your expense. If growing is your object in addition to discovering origins, the following will suit you:—*Diadematum*, *Bridal Ring*, *Sidonie*, *Cardinal de Richelieu*, *Ignescens*, *Madame Csillag*, *Lady Mary Fox*, *Unique*.

Chrysanthemum in Pots.—Ne Quid Nimis asks, "In how small a pot will the above flower effectively, and how many may you safely venture on in a 10 or 12 inch pot? I have got nice heads of bloom in 4-inch pots, with the soil as hard as iron." We presume the query refers only to the large-flowering kinds, and thereto we reply that we have flowered the large varieties in 48-size (5-inch) pots, and had an average of three and four splendid flowers each. The plants, of course, were on single stems, and had the aid of liquid manure. That is an extreme case. In 10 or 12 inch pots, half-a-dozen flowers are as many as can be relied upon to have them good; but if mere colour and not quality is desired, they may be allowed to carry all they show, and the result will be some two or three dozen flowers on the free varieties, but of course no quality. When our correspondent asks "how many," we suppose him to mean how many flowers, for only one plant should be allowed in a pot. Again, our correspondent says, "This year one of our growers in his instruction book says you cannot give the plant too much room in the early stages of its growth. This doctrine is entirely opposed to the old theory and practice, so far as I understand it, which is to gradually increase the size of your pots till you come to the flowering pots; and by their being a little pot-bound in the earlier stages of their growth they are kept to a more manageable size, and have a tendency to show flower-buds earlier. This being another case of doctors differing, there is nothing left but to go to the consulting physician." If our correspondent quotes correctly, we are bound to say that the expression "cannot give them too much room" is nonsense, because one might fill a hog'shead with soil and stick a cutting in the centre, and still be complying with the author's teachings. But the error is not one of practice but of language, and is evidently intended to guard the amateur against the baneful practice of allowing young plants to remain for a long time starving in small pots containing only poor sandy soil, such as is commonly used for the first start in growing almost every kind of plants from cuttings. If he has a clear notion of what should be done, though not a master of language, he would say, Be careful not to subject your young plants to severe checks, for it is an injury to cause a premature hardening of the wood; the best plants when in flower are those that were encouraged to grow freely when young; the hardening of the wood is a process proper to the end and not to the beginning of the growth, and a pot-bound condition, such as takes place after the last shift is accomplished, is a condition eminently favourable to the ripening of the wood, and to the subsequent production of fine flowers. "Ne Quid Nimis" is just wrong in supposing that "a pot-bound condition

in the earlier stages of growth" is beneficial; it is in fact injurious; and the most successful exhibitors are those who take care to keep their plants always growing from the first until they are in the flowering pots, when growing ceases, and the ripening of the wood begins.

BOTTOM HEAT FOR VINES.

Gardeners have for many years felt that it was exceedingly unnatural to place the branches of the vine in a high temperature, while the roots were in the cold soil of the border outside the house, and they have had recourse to various expedients to remedy this clearly recognised evil. Hot fermenting dung and leaves have been applied to the surface of the border, which did some good, more by its negative than its positive action, in so far as if the heat from it did not penetrate the border to any depth, it at least, if applied in autumn, prevented the escape of the heat the border had derived from the sun during the summer. Wooden shutters, and in some instances glass, have been laid on the surface of the border to prevent the radiation of its natural heat. All these methods were well known to be very defective; and it is only of late years that the beating of vine-borders from beneath by means of hot-water pipes has placed the temperature of the roots as completely under the gardener's control as that of the branches has always been. Where the expense of stone pavement for covering the pipes is an objection to its use, the same end may be arrived at by first laying the pipes on pieces of half-inch round iron, resting on a smooth stone surface, at intervals of nine feet apart. These bits of iron will act as rollers, and enable the pipes to expand and contract without the risk of "drawing" the joints. The pipes should then be covered with a small brick drain full of loopholes on each side, taking care that none of the covering bricks rest on the pipes. From these loopholes hot-air drains should be run right and left with dry bricks, or by using common drain-tiles, on the top of which six inches of brickbats should be laid, and then the turf, as already recommended.

The mere heating of the soil of the border by these appliances is not the only advantage that results. There is the additional and important one of the constant passage of air through the soil, forced up through it when heat expands that in the air-drains and interstices amongst the brickbats, and down through it when the air in the drains cools and contracts.

When the difficulty of getting a boiler fixed at a sufficiently low level to heat the pipes for warming the border cannot be overcome, as must often be the case where the country is level and the drainage bad, the best substitute is to make all the arrangements as to air-drains I have described as necessary when pipes are laid, and to connect these subsoil air-chambers with the atmosphere of the interior of the vinery by a series of drain-pipes along the front of the house near the hot-water pipes. Along the back wall of the vinery construct an underground air-drain, to be connected by a series of pipes, four inches in diameter, with the general underground air-chambers of the border. From this drain another series of pipes should be carried up the back wall some seven or eight feet, where they should have openings into the interior of the vinery; and if the flue from the boiler is made to run along the back wall in such a way as to heat the air in the upright air-drains, it will become lighter, and escape into the general atmosphere of the house; while at the same time a current of air will pass down the front air-pipes, already referred to, at a lower temperature than that escaping from the outlets in the back wall, but sufficiently warm to be of great benefit to the roots of the vines. This arrangement has the additional advantage of keeping the air in the house in constant motion. There is also the possibility of making such arrangements in forming a vine border as to admit of the application of warm dung-linings, which answer the same purpose. It is, however, only necessary to have heat applied to the roots, as here described, in cases where grapes have to be forced early. If the vines are not started till the beginning of March, they will do perfectly well without it, as is evident from every-day experience.—W. THOMSON, *Cultivation of the Grape Vine.*

LISYANTHUS RUSSELLIANUS.

The best time to sow the seed is in March, and as the seed is extremely small, it requires particular care. If deposited in the usual way upon loose soil, the first watering carries the seed along with it, and hence the failure. Prepare the following compost: half loam, the other half leaf, peat, or bog mould, and a little sand; place plenty of drainings in the bottom of a 48 or 32 pot; fill it with the compost very tight, and on the top place half an inch of sand; damp the sand with water to harden the surface; sow the seed, and sprinkle a very little dry sand on the top. Place a propagating glass over the pot, or a piece of flat glass will do; place the pot in a heat of 70° or 80°, with a pan under for future watering; at no time water on the top, but the pan ought never to be allowed to get dry. The seedlings will appear in three weeks or more; when about three weeks up, plant them singly in a 60-pot, in the same compost, with plenty of drainings in the bottom. Place them again in the back of your cucumber-pit or frame; after this you cannot give them too much water over head and in the pans, and by the autumn, if they have been kept in a good growing heat, they will be fine little bushy plants. Top them at every joint; in September shift them into large sixties, merely to keep their roots in a more intermediate state for the winter; after this, all top watering must cease, and a pan placed under each pot to receive the watering. As the winter approaches, not a drop of water must be allowed to fall on the plant. The drier the top mould next the leaves and stem, the more certain of preserving the plant. The best place I have found is a one-light pit heated with a lining of dung from 50° to 60°, air being given front and back, so that no damp can fix on the bars and drop on the plants. The second best place is the coldest part of the stove, very near the glass; I have also kept them well in the warmest part of the greenhouse; in all cases, water just sufficiently to keep the plant from flagging; if the winter is dry, once a fortnight, if damp, once a month or so. Towards the end of February place them in a cucumber-pot or frame, in a heat of from 70° to 76°, and when they begin a fresh growth shift them into as large pots as convenient, remembering the larger the pot the finer the specimen. As the spring advances, it is almost impossible to give too much heat and moisture. They are very fond of liquid manure. It is useless to attempt to grow a fine plant in any place approaching to a dry heat, or in a temperature of less than from 70° to 80°. I have grown them five inches in seven days, and have had six hundred flowers on a plant at one time. In removing them out of the pits, great care must be taken to prevent the sun shining on them for some days, as the change from a damp close heat to a dry house will be too much for them. By the above treatment they will come into flower about the middle of July, and keep blooming from two to three months. It is far better to grow this plant from seeds than from cuttings. JAMES CUTHILL.

The Gardener's Magazine.

SATURDAY, JULY 6, 1867.

TRIALS OF PEAS HAVE NOW BEEN MADE TO A SUFFICIENT EXTENT to determine the relative values of all the varieties in cultivation; and though we may expect in the future a constant succession of new or professedly new varieties, which it will be necessary to compare with established sorts, there will not henceforth be felt that interest in the subject which has prevailed during the past few years. We reported in our issue of June 15th that all the early sowings of trial crops at Stoke Newington had perished, but that sowings of peas made on the 2nd of May were doing well. The greater part of the collection is now in flower, and many of the earlier kinds are in a fit condition for gathering. We shall in due time report upon the whole, but with less detail than last year, and we shall again have to show that FIRST CROP, alias *Carter's First Crop*, alias *Sutton's Ringleader*, is the earliest variety in cultivation, and distinct in several particulars from all others. Within a week of this date, the distinctive qualities in several of the earlier sorts will, with us, be most prominent, as, although it is in the first gatherings of certain kinds that we detect certain peculiarities and relationships of the highest importance, we cannot determine the position or value of any one kind until we have observed it through all its stages, and have seen not only how it lives, but how it dies. As it has been so frequently stated that First Crop and Dillistone's Early are the same, we would point to two obviously distinctive features. The first named comes into bearing and gives good supplies several days in advance of the second, but has finished its course, and may be cleared off the ground, while the other is still fresh, tolerably well covered with pods, and perhaps still showing a few flowers. The variety which most closely resembles First Crop is Dickson's FIRST AND BEST, which is a few days later in affording a first gathering, but is extremely fruitful, and finishes its course suddenly, like the First Crop.

It is a matter of so much importance to both private growers and those who grow for market to determine which amongst the many is really the earliest pea, that we must not consider time or space misspent if we can promote the clearing up of the questions that have arisen during the long and conflicting discussion of this subject. It will be remembered that in 1865, when First Crop was first distributed, the Fruit and Vegetable Committee of the Royal Horticultural Society reported that it was identical in every respect with Dillistone's Early. In 1866 we pointed out the differences between them, but in that same year the Fruit and Vegetable Committee made no report, for the Chiswick peas were destroyed by mildew. This year the Fruit and Vegetable Committee have the start of us, for their early sowings were not destroyed by frost. They now report, as in 1865, that Dillistone's Early, First Crop, and Veitch's Early are perfectly identical. But they have made a discovery of quite a startling nature, namely, that Dillistone's Early is not Dillistone's Early, but something else. They say that the confusion that has arisen is the result of Mr. Dillistone having sent out a spurious stock of his Early pea, and they call upon him for an explanation. They do not openly acknowledge having made a blunder, but they indirectly confess there is something wrong somewhere, and throw the burden of proof of what is the actual truth on a person who has nothing at all to do with the trials or the discussions. Men who love the truth, without regard to persons, parties, and interests, will scarcely be satisfied with this mode of dealing with so important a matter. In the first instance, the Committee hinted that Messrs. Sutton and Carter were parties to a dishonourable proceeding, namely, the sending out of an established variety of pea under a new name, with a new character, and at an advance upon the market price. They make the same report in 1867 as in 1865; but they select another victim, for now they say Mr. Dillistone is the offender, for Dillistone's Early of Dillistone is not Dillistone's Early of Chiswick, but a badly mixed stock of Sangster's No. 1. Now we know something of Dillistone's pea. It has been grown at Stoke Newington every year since 1862, has been obtained every year from two or three different houses, and has always been the same. The samples supplied by Mr. Clark, of 42, Bishopgate Street, in 1865, were the same in growth and every character as we had from Mr. B. S. Williams and Mr. Dillistone in 1866, and agreed precisely with the description of the variety in the Chiswick report of 1861. The Fruit and

Vegetable Committee do not inform us how they have become possessed at last of the true variety; they leave the whole affair in a fog, with a vague reference to "a London house," and call upon Mr. Dillistone to clear up that which they profess to settle themselves by the aid of almost superhuman knowledge, yet with the vagueness and incertitude that belong to supernatural things. We cannot help thinking of the cuttle-fish, which, when assailed by an enemy, discharges an inky fluid which confounds its pursuers, and affords it a chance of escape from a difficulty under cover of an extemporized darkness; or of that particular species of beetle which naturalists tell us emits an abominable odour when involved in a perplexity, and which keeps its enemies at bay by its own repulsiveness. The position of the First Crop pea is, at all events, established, and two out of three respectable trading houses that have been vituperated are vindicated by the facts, though the intentions and feelings of the Committee are as dishonourable as heretofore. In respect of the attack on Mr. Dillistone, we are willing to wait to learn the truth, and have no doubt at all that gentleman will be found well able to take care of himself.

THE JUDGING OF PLANTS AND FLOWERS CANNOT BE GOVERNED BY THE SAME RULES. A plant may be well grown, but the variety selected may not be the best in cultivation; a plant may be badly grown, but may be the best variety known in its class; and if the two are placed side by side as plants, we ask which is to be placed first and which second? The question is one of some importance, and amongst judges there appears to be considerable difference of opinion on this point. Some will vote for the best plant as a plant—that is to say, in regard to contour, training, freshness, abundance of flowers, and effective colouring; and some will favour the best flowers, making light of defective training and that peculiar freshness and finish which are by others regarded as essential in a specimen. At the first great show at the Crystal Palace, Mr. Turner's great azaleas were placed second to Messrs. Glendinning's—justly, as we thought, because one of Mr. Turner's plants had been half blown away or frozen on the road, and was in an unrepresentable condition; whereas Messrs. Glendinning's were all fresh and covered with large flowers, with bits of bright green foliage peeping out all over them; though, as to size, Mr. Turner's were gigantic, and Messrs. Glendinning's were of useful dimensions for embellishing any good conservatory. But, at the second great show at Regent's Park, Mr. Turner put up a group of gigantic specimens, which were equally finished and fresh throughout; and Messrs. Glendinning presented just such plants (the same, perhaps) as were so successful at the Crystal Palace, and again obtained the first position. In our reports of these exhibitions we gave free expression to our opinion on the awards, but of course did not stop to argue the question. We now ask if the judgment was as good in the second instance as in the first? Let it be understood that we are cognizant of the facts of the case in each particular instance: in both cases Mr. Turner's flowers were inferior to Messrs. Glendinning's; but at Regent's Park Mr. Turner's were well matched in size, any one of them was equal to the whole group (or nearly so) put up by the Chiswick firm, and they were literally sheeted with colour, were without blemish, were abundantly various in character, and as specimens had no equals in the entire exhibition. We repeat, after some deliberation, the opinion expressed in our report, that they were properly first, and those placed first were properly second. A similar case occurred at the last Cambridge show. Messrs. Wood and Ingram put up a group of pelargoniums superbly modelled to convex outlines, dense, leafy, flowery, and fresh. Mr. Heady put up a group very finely turned out, but wanting the finish, the brightness, the denseness of the Huntingdon collection. But there was this great difference between them—Messrs. Wood and Ingram's were not first-rate sorts; they were highly effective as to colours, but some of them were sorts that give rough long-petalled flowers; whereas Mr. Heady's were in every case the best varieties in their several shades of colour, and the flowers were finely produced, with broad petals, and every other peculiarity that a florist would rejoice in and understand by the collective term "quality." We cannot expect all our readers, however experienced in the judging of productions submitted to competition, to agree with us when we say that in the case of the azalea competition at Regent's Park the judges were wrong, and in the case of the particular competition referred to at Cambridge they were right. We repudiate all personal feeling in the matter;

we are anxious only about the establishment of principles. It appears to us that when *plants* are to be judged, we must not follow the rules that guide us in the judgment of *flowers*. A man may select the very worst varieties, and yet turn them out so well as to surpass by many degrees the plants from another cultivator who has made a better selection, yet has failed in many respects to do them justice. Are we, then, to place selection before cultivation? We think not. Take an extreme case, for that is always a proper mode of determining a nice matter. Suppose a man brings a group of pelargoniums finished in the style of a Turner or Fraser, say five feet across, measured by a tape laid across from the extreme outer points, and in this group are varieties not quite so good as John Hoyle or Fair Rosamond. Another brings a group in 48-sized pots, just purchased but comprising the very best that can be had, with one or two flowers each, superb in outline, and just such models as Mr. Andrews would delight to make drawings of. This is an extreme, an impossible case as schedules are framed; but suppose it, and to whom would you award the first prize? To the specimens undoubtedly. And why? *Because as plants they are the best!* A principle is a principle; and if it applies to an extreme case, it applies to all. That many points should be considered in judging we readily admit; a man of one idea is quite unfit to act as a judge. If two groups of plants are equally balanced as to merit of cultivation, and we cannot make a distinction between them on that ground, the next thing to be done is to see who has the best flowers. If in one group there is a preponderance of ill-formed rough flowers, and in the other a preponderance of round, broad-petalled, smooth flowers, then we say without hesitation the best flowers must have the first place; but we must consider cultivation first, and quality of flowers afterwards.

It may be said in defence of the judgment of the azaleas at Regent's Park, that the judges were anxious to discourage the production of gigantic plants that are useful only on such occasions, and that cannot possibly be turned to good account in any ordinary private establishment. Mr. Turner's gigantic azaleas are confessedly show subjects, and Messrs. Glendinning's pretty little plants are of a size and shape that fit them for many uses to which the others are not applicable. But if we have great exhibitions we must expect exhibition plants, and it is an open question whether judges are to determine, not what is most meritorious amongst things submitted to them there and then, or what is best adapted for this or that particular purpose other than the occasion which has called them together. Are judges to be arbiters of fashion, or of the respective merits of the things they see? Of the things they see, we say, for fashion has a law of its own, and if you discourage great specimens for a few seasons, they will reappear, and again be in favour; and as the fashions change in the world at large, so will the opinions of judges vary as to what is and what is not desirable, and they had best have nothing to do with fashion at all, but judge plants as plants, and leave all other matters to settle themselves. We offer these remarks in the most friendly spirit possible, and in the interests of horticulture solely. If we are wrong, we are willing to be corrected. Generally speaking, the judging at exhibitions affords small grounds for complaint, but much for satisfaction; yet the smallest error is worth consideration, and we can only do justice to all the interests concerned by discussing these questions on the broad ground of principle, leaving interests and personalities out of the case altogether.

CALCEOLARIA DISEASE has broken out in several of the great gardens in the southern counties during the past week, and where there was a brilliant display of golden flowers there are now shrivelled bits of brown leaves or blanks so numerous that the beauty of the beds is past for the season, unless they are at once replanted with some other subjects better suited to endure hot sun and drying winds. We saw in a contemporary a few weeks since an elaborate inquiry into the causes and nature of the disease, from the pen of a writer signing "M."; but not a word was said as to prevention or cure. Let it be fungoid, what then? No doubt Mr. Berkeley is right, though it is his peculiar gift to find fungi anywhere and everywhere, and probably he could trace mycelium in the Reform Bill. As our contemporaries occasionally appropriate our ideas and suggestions without acknowledgment—an ancient vice of high-priced papers—we think it proper just now to remind our readers that we have several times pointed out a certain method of preventing calceolaria disease. In beds formed almost wholly of thoroughly decayed and pulverised manure the disease never appears. At all events, during the past seven years we have treated calceolarias in this way, and they have been robust in health and brilliant in appearance whilst others planted in ordinary beds were perishing. There should be at least nine inches depth of soil, consisting of at least three or four parts of manure rotted to powder to one of mellow loam, and in such a compost calceolarias will make a vigorous growth and flower profusely till quite the end of the season. Of course, many will say they cannot command manure

in sufficient quantity, but our business is to state what we know, and if the only soil fit for the purpose was one consisting of gold-dust we should be bound to chronicle the fact.

THE ROYAL BOTANIC SOCIETY'S THIRD SHOW took place on Wednesday last. It was an interesting and brilliant affair, particularly rich in fine-foliage plants, large-flowering and zonal pelargoniums, and new plants. Owing to the multiplicity of our engagements, we are compelled to defer the publication of our report till next week. The attendance was not large, and unfortunately there was so dense a fog throughout the afternoon that it was scarcely possible to see any of the plants or flowers enjoyably.

THE BIRMINGHAM ROSE SHOW proves to be the best rose show of the season, whether because of its later date or because of a more enthusiastic devotion to the rose in the midland counties than elsewhere, we do not pretend to say; but we think the date must have much to do with it. Certainly, for number and quality of roses, the Birmingham Exhibition is the great event of the season.

THE HARVEST IN FRANCE has already commenced, and in a few days the Emperor will be presented with a loaf made from this season's wheat.

FARMING THE PRAIRIES.—A correspondent of the *St. Louis Democrat* says: "The productive prairies of the Mississippi and Alabama are all under cultivation—one half in corn and one half in cotton; and what is still more gratifying, the freedmen are, as a general thing, working remarkably well."

THE CROPS IN ALL PARTS OF THE UNITED STATES are reported to be in excellent condition, and promising an abundant yield. For instance, the Indian corn crop this year is estimated at 1,200,000,000 bushels as compared with 868,000,000 bushels last year.

THE INTRODUCER OF THE POTATO.—A wealthy citizen of Berlin has applied to the municipality of that town for a site on which to erect a statue to Francis Drake, as the introducer of the potato into Europe, and offers to subscribe 15,000 thalers (£2,250) towards the statue.

SOMETHING NEW IN THE FLORAL DECORATION WAY.—A Nashville paper says, that at a recent wedding in that city "the bride and bridegroom knelt and joined hands from opposite sides of a table, in the middle of the altar, on which was an open Bible covered with a wreath of flowers. A beautiful pyramid of flowers was suspended over their heads from the ceiling."

WATERPROOF PACKING PAPER.—The following is a German recipe:—Dissolve 680.4 grammes (about 1.82 lb.) of white soap in a quart of water. In another quart of water dissolve 1.82 oz. of gum-arabic and 5.5 oz. glue. Mix the two solutions, warm them, and soak the paper in the liquid. Pass it between rollers, or simply hang it up to drip, and then only at a gentle temperature.

THE FROST OF MAY 23, 24, AND 25 LAST.—The full extent of the mischief done to vegetation by the severe frost which occurred in the end of May (says the *Edinburgh Courier*) is only now beginning to be fully comprehended. In the gardens, potatoes, strawberries, blackberries, gooseberries, and red and white currants have suffered severely, and will in most cases prove a very light crop. In the orchards, apple, pear, and plum trees have also been much injured. But the ravages of Jack Frost's farewell bite have not been confined to gardens and orchards alone. The woods and hedgerows have also been subjected to the blasting influence. Ash, beech, larch, spruce, and Scotch fir trees are all more or less brown and withered in their foliage. The vales of the Borthwick and Teviot seem to have suffered the most of any part in this locality. The whins in all the fox covers around here are quite brown, with hardly a spot of bloom. The generally beautiful Galalaw cover, which at this season of the year used to delight the eyes of all by the blaze of yellow bloom which arose from its sides, is this year as brown as the winter heath. Borthaugh, Chapehill, and Drinkstone covers have all, to a greater or less extent, shared the same fate, and will require two or three seasons at least to restore them.

A SHOWER OF HAZEL NUTS!—The following correspondence may interest the lovers of the marvellous:—

To the Editor of the *Meteorological Magazine*.

SIR,—I enclose you two extracts from one of our Dublin papers relative to some berries, which are reported to have fallen in large quantities in some parts of Dublin on the night of Thursday, 9th May. I have been given two of these berries; they are in the form of a very small orange, about half an inch in diameter, black in colour, and, when cut across, seem as if made of some hard dark brown wood. They also possess a slight aromatic odour. Various speculations have been given forth as to their origin, but none of them seem to be worth much. If you think the extracts herein worthy of a place in your Magazine, you can insert them. Yours very truly,

ARTHUR PIM.

Monkstown, Dublin, June 1st, 1867.

THE SHOWER OF BERRIES.

To the Editor of the *Daily Express*.

SIR,—I have been daily expecting to see some notice of the strange phenomenon which took place during the tremendous rain-fall of Thursday night. None have appeared in any of the journals. I hope, through your columns, the public may learn to what cause we are to attribute the shower of aromatic smelling berries which fell over Dublin (and, possibly, other parts) on Thursday night.

Both on the north and south sides of the river these berries fell in great quantities and with great force, some being larger than the ordinary Spanish nut. Numbers of these strange visitors were picked up in Capel Street, in Dame Street, and Bishop Street, and I am informed that so violent was the force with which they descended, that even the police, protected by unusually strong head covering, were obliged to seek shelter from the aerial fusillade!

Yours truly,

T.C.D., May 13th, 1867.

RUSTICUS EXPECTANS.

INQUIRER, who has sent us some "small balls," which he says "fell in large quantities on Thursday night," locality not specified, is informed that they are simply hazel nuts preserved in a bog for centuries. How they came to descend on him we cannot say.

IMPORTATION OF PROVISIONS.—The grain and provision merchants of Paisley have recently been agitating in favour of the abolition of the Customs dues. An association has been formed for the purpose.

WORKING MEN'S FLOWER SHOWS continue to prosper and increase. There was a very interesting exhibition of this class in Great Dean's Yard, Westminster, on the 28th of June, when the Earl of Shaftesbury gave away the prizes. On Wednesday next a similar exhibition will be held in Elder Walk, Islington, when the Rev. Dr. Raleigh will give an address. Messrs. Duncan and Drummmond are labouring hard to promote an exhibition of plants belonging to the working classes of Edinburgh on the 3rd of August, when about three hundred prizes will be offered. This exhibition will take place in the Corn Exchange, Grass Market, Edinburgh.

DESTRUCTION OF SMALL BIRDS.—Every year at this season the papers teem with remonstrances against the wholesale destruction of little birds, which causes so much injury to the crops. The Minister of Agriculture has addressed a very clever circular to the mayors of France, enjoining them to punish severely all persons caught in the act of netting, trapping, &c., small birds, whose valuable services as destroyers of insects he sets forth, demonstrating by statistics the utility of these humble members of the feathered tribes.

A RACE FOR CUTTING DOWN TREES.—Our contemporary, the *Athenaeum*, directs attention to the mischievous effects of the reckless cutting down of trees in France and southern Europe, where the climate becomes every year drier, and the soil is washed away by destructive floods, to the impoverishment of the whole provinces. Warnings have long been uttered by competent overseers, but in vain; a sort of race for cutting down woods has prevailed for the last two centuries. But at length the people most interested—the inhabitants of the countries involved—have begun to open their eyes to the question, and a petition has been laid before the French Senate, which points out that the army might be employed in planting trees on the now barren hill slopes and plains. It would be something now to exercise soldiers in so peaceful and beneficial an undertaking, and we should be glad to see the experiment tried. Planting might prove more profitable than fighting; plenty would replace penury, and the meteorologists would have the opportunity of witnessing a singularly interesting experiment.

HORTICULTURE AMONGST THE FREED NEGROES.—In the report of the Friends' Association of Philadelphia, it is stated that the distribution of garden seeds among the freedmen, as extensively as our acquaintance reaches, has been of peculiar advantage. The evidences of last season's culture prove the effect of this kind of charity in promoting industry and forecast. Testimony was given us showing that the distribution of seeds last year resulted in actually saving human life. The donation of garden and other seeds may seem a small matter, but when in addition to the healthful supplies derived from this source, we take into account the discipline of fencing, planting, tilling, and the patient waiting for the "early and the latter rain" which it involves, the influence must be great upon a people by nature and education remarkably improvident.

CULTIVATION OF BEET.—The cultivation of the beet-root, for the sake of the spirit and sugar it contains, is attracting attention in Australia. The patent for the manufacture of spirits from beet-root by steam has been secured for Messrs. John Levy and Sons, and we learn from the *Melbourne Argus* that the firm received from France a package of 200 lbs. of beet-seed. As illustrating how disadvantageously Australia is situated in these matters, we may mention that the original cost of the seed was but £10 10s., and yet the freight from France to Melbourne amounted to £17 10s. 7d.; the Customs duties and charges connected with the entries necessary to pass the goods amounted to 18s. 3d. While on this subject, we may remark, in connexion with the valuable prize cup offered by Messrs. John Levy and Sons, through the Board of Agriculture, for the best crop of beet root, that the Board has not given attention to the reasonable suggestion that the adjudication should be postponed for another year, as only four competitors entered their names, and the extent of land under beet-root represented by those entries did not exceed sixteen acres. Such a competition as this, it was obvious, would serve but little the purpose for which the prize was offered. The board, however, had the cool assurance to intimate that they had appointed four gentlemen to examine the four crops entered for competition, and to ask Messrs. Levy and Sons for a cheque to meet the expenses of those judges, as the board "had no funds at its disposal (the large annual Government grant notwithstanding) to apply to such purposes"!

CRYSTAL PALACE ROSE SHOW.

SATURDAY, JUNE 29TH.

The opinion held by rosarians who were present at last Saturday's exhibition was that the show was highly creditable alike to the place and the competitors. It has been so bad a season that we might not have been rash had we predicted there would be no show at all; yet despite a thousand adverse influences, a dreadful winter, a wintry spring, and, not the least important of all, intense sunshine and a cold parching east wind three weeks previously, the exhibition of Saturday last was scarcely inferior to some of the best rose shows held there, and in many instances the flowers shown were truly magnificent. There were certainly many visible indications of the unsuitableness of the season for a good bloom of roses. In the first place, there was not a perfect group in any of the large classes, not even in the 48's. The finest collections contained faulty flowers, and in some instances the faulty ones were so bad, as compared with the splendid examples with which they were associated, as to prove that in cutting and preparing for the show the cultivators were severely tried to find flowers enough for their boxes. A very interesting feature of this show was the general excellence of the collections from amateurs. We may be honnd to take especial note of trade contributions, for the simple reason that the trade can show new varieties best, because they obtain them first, and also because of the generally large extent of their plantations. They are as it were bound to lead the way and show the largest collections. But the estimation in which the rose is held can be judged only by a review of the contributions from amateurs. If private growers do not take some pride and bestow some care in the cultivation of the flowers, nursery manipulations and enterprises are all in vain. It was therefore with exceeding satisfaction that the rosarians who met at Sydenham on Saturday last found the amateur collections in advance of the average of former years, and in many instances the flowers were equal to any that have been seen at rose shows during the whole time that such meetings have been instituted. There were some

novel features too to give interest to this meeting. There were prizes offered for collections of yellow roses, and for collections of tea and noisette roses, and our frequent suggestions in behalf of encouraging pot roses were carried out, and the result was some good groups of plants. Interesting as were the collections of yellow roses, and tea and noisette roses, they were scarcely effective, and we cannot afford to tolerate a single ineffective feature in a rose show. To be sure, the lack of effect was due in great part to the lack of good flowers in these classes; nevertheless there is weakness and indecision in groups of yellow and tea roses; they really want strong colours to bring them out. Let any of our friends who saw all the flowers call to mind how gloriously shone a single *Maréchal Niel* in Mr. Hedgo's 48, where it was associated with high-coloured flowers, and how comparatively weak in appearance was the same rose, though well done, in several other instances, where it was grouped with roses of its own class. Probably the ends sought to be accomplished by these now classes, might be attained by instituting classes for 24, 18, and 12 roses, to comprise 8, 6, and 4 yellow flowers respectively. Such a mode of displaying yellow roses would enable the exhibitor to associate them with high-coloured flowers, to afford suitable contrast, and the stands so filled would have a charming appearance. We may be able to return to this subject, and perhaps amplify the suggestion; but for the present we commend it to the consideration of our friends of the rose world, while its value can be tested by exhibition facts.

Those of our readers who are familiar with past reports of Crystal Palace rose shows will remember that this is not the first time we have had to record that the affair was saved by the skin of its teeth. We have become quite familiar with had seasons and with an unsatisfactory first bloom. Yet it is desirable to hold such an exhibition as that of the Crystal Palace as early as possible, and we cannot fairly say that the directors are in too great haste in fixing the date of the show. Delay would cause it to clash with others, and the commercial considerations necessarily compel the promoters to the course they follow, or at least very nearly so. But there is yet a possibility of fully gratifying the lovers of roses and of doing full justice to the flower, and that is to hold another show this year, say about the 3rd of August, or at whatever date may be best for securing the best of the second bloom. Let us now proceed to the classes. The greatest class was that for 72 varieties, one flower of each, and in this there was a spirited competition. The first place was taken by Mr. J. Cranston, of King's Acre, Hereford. Messrs. Paul and Son and Mr. Mitchell, of Piltown, also exhibited.

MR. CRANSTON'S FIRST PRIZE, SEVENTY-TWO.—Madame Brianson, a splendid large flower, rather flat; Madame Moreau, Paul Ricaut, William Jesse, *Maréchal Souchet*, Margaret St. Amand, Madame Victor Verdier, Souvenir d'Elise, Maurice Bernardin, Jean Goujon, François Lacharme, Madame Boll, showing a big eye; Horace Vernet, fine; Comte de Nanteuil, Christian Puttner, beautifully folded, crimson purple, a charming flower; Thorin, a fine rose; Louis Van Houtte, Madame Eugène Verdier, Madame Pauline Villot, Alpaide de Rotalier, Duke of Wellington (to call this a "Duc" is simply to insult the memory of one of our own heroes), La Esmeralda, Napoleon III., Souvenir de la Malmaison, Beauty of Westerham, Centifolia Rosea, Dr. Andry, Duchess of Orleans, Gloire de Montplaisir, Madame Clémence Joigneaux, Lord Clyde, Gloire de Dijon, Claude Million, Madame Vidot, Charles Verdier, Duchesse de Caylus, Pauline Lansezur, Madame Domage, Madame Crapelet, Madame Bravy, Prince Camille de Rohan, Caroline de Sansal, Jules Margottin, Baron Gonella, King's Acre, Sénateur Vaisse, Céline Forestier, Madame Charles Wood, an enormous flower without a shadow of coarseness; Joseph Fiala, Madame Knorr, Baron de Noirmont, Anna de Diesbach, Le Rhône, Louise de Savoie, General Jacqueminot, Mrs. Rivers, Pierre Notting, Madame William, Prince Henri de Pays Bas, Charles Lawson, Charles Lefebvre, Niphetos, Lord Macaulay, Charles Margottin, Admiral la Peyrouse, Comtesse Cécile Chahillant, Devoniensis, Madame Hector Jacquin, Souvenir d'un Ami, John Hopper, fine; President, Souvenir de Charles Montault.

MESSRS. PAUL AND SON'S SEVENTY-TWO.—Xavier Olibo, Alpaide de Rotalier, Alfred Colomb, Sophie Coquerel, a saucer; *Maréchal Vaillant*, Madame Clémence Joigneaux, Claude Million, Joseph Fiala, Triomphe de Rennes, Madame Boll, Sénateur Favre, Madame Caillat, Maurice Bernardin, Madame Rivers, Prince Camille de Rohan, William Griffiths, Rushton Radcliffe, Impératrice Eugénie, Madame Boutin, Duchess of Orleans, Duc de Rohan, General Jacqueminot, Antoinette Ducher, a beautiful closely-built globular rose; Alba Roses, La Fontaine, Madame Furtado, Prince de Porcia, Abel Grand, Sénateur Vaisse, Madame Villermoz, John Hopper, Lord Canning, Beauty of Waltham, Margaret St. Amand, Gloire de Vitry, Leopold I., Victor Verdier, Madame C. Wood, Queen Victoria, Exposition de Brie, Madame Thérèse Levat, small hut neat; Leopold Hausberg, President, Charles Lefebvre, Monsieur Woolfield, very large, globular; Triomphe de Caen, Dr. Andry, Madame Victor Verdier, Comte de Nanteuil, Mlle. Gabriel Peyronny, Mlle. Margaret Dombain, Le Rhône, La Reine, Marie Baumann, fine; Souvenir d'un Ami, Baronne A. de Rothschild, Gloire de Dijon, Lord Clyde, Madame Derreux Douville, Olivier Delhomme, Charles Verdier, Vicomte Vigier, Lelia, Madame Crapelet, remarkably fine; Madame Margottin, Pierre Notting, Josephine Beauharnais, François Treyve, La Ville de St. Denis, Duke of Edinburgh, Madame Vidot.

MR. MITCHELL'S SEVENTY TWO.—Madame Furtado, Souvenir d'un Ami, Pierre Notting, Gloire de Ducher, La Ville de St. Denis, Anguste Riviere, Madame Hector Jacquin, Duke of Wellington, Duchess of Orleans, Mlle. Gabriel Peyronny, Eliza Sauvage, Olivier Delhomme, Centifolia Rosea, John Grier, Baron Gonella, Louise de Savoie, Queen Victoria, François Louvat, Madame Vigneron, Leopold I., Madame Eugène Verdier, Bernard Palissy, Mlle. Margaret Dombain, Madame Caillat, Vicomtesse de Cazès, Charles Lefebvre, Madame Charles Verdier, a had rose; Josephine Guyot, La Reine, Dr. Andry, Colonel de Rougemont, one of the most horrid of the pancake class; H. Laurentius, Louis Peyronny, Duc de Rohan, Josephine Malton, Madame Victor Verdier, Vicomte Vigier, *Maréchal Niel*, La Tour de Crouy, Gloire de Santhenay, La Globuleuse, a beautiful globular shaded rose, distinct, delicate, and refined; Baronne A. de Rothschild, Souvenir d'Elise, Comte de Paris, Lamarque, John Hopper, Céline Gonod, Margaret St. Amand, Jean Lambert, Souvenir de la Malmaison, Madame Boutin, Madame Filion, Leopold Hausberg, Anna de Diesbach, General Washington, Madame Boll, Madame Charles Wood, Madame Clémence Joigneaux, Madame Charles Crapelet, Xavier Olibo, *Maréchal Souchet* (Damaizin), Caroline de Sansal, Gloire de Dijon, Le Rhône, Sénateur Vaisse, Triomphe de Rennes, Victor Verdier, Sénateur Favre, General Jacqueminot, President

Mas, Maurice Bernardin. It appears from my note-book that in this lot there were duplicates of at least three varieties.

The most effective groups in the whole of the exhibition were those in the class for forty-eight, three trusses of each. The number suffices for a fine display, and there is more scope for tasty setting up when three trusses are allowed. The first prize for forty-eight, from Messrs. Paul and Son, were doubtless the finest lot of roses in the show, various in colours and styles, most tastefully disposed in respect of buds and leaves, and, generally speaking, the flowers were grand in character and marvellously fresh. Mr. Mitchell, of Piltown, presented a very fine collection in this class, the arrangement of which was admirable.

MESSRS. PAUL AND SON'S FIRST PRIZE, FORTY-EIGHT.—Madame Crapelet, Souvenir d'un Ami, Mlle. Margaret Dombrain, Vicomte Vigier, Caroline de Sansal, Joseph Fiala, Comte de Nanteuil, Baronne A. de Rothschild, Madame Boll, Sénateur Vaisse, Madame Charles Wood, Gloire de Dijon, Amabilis, Maria Baumann, Alpaïdo de Rotalier, Lord Macaulay, Manrice Bernardin, Michel Bonnet, Madame Victor Verdier, Margaret St. Amand, Madame Bravy, Olivier Delhomme, Madame Rivers, Sénateur Favre, Triomphe de Rennes, Charles Lefebvre, John Hopper, Xavier Oliho, Beauty of Waltham, Souvenir de la Malmaison, Prince Camille de Rohan, Madame Caillat, Leopold Hausberg, Comtesse Cécile Chabillant, Lord Clyde, Victor Verdier, La Brillante, Claude Million, General Jacqueminot, Jules Margottin, Madame Boutin, fine; Louise Margottin, Le Rhône, fine; Madame Vigneron, Gloire de Santhenay, William Griffiths, Maréchal Vaillant.

MR. MITCHELL'S FORTY-EIGHT.—Madame Crapelet, Duchess of Orleans, La Tour de Crouy, Sénateur Vaisse, Souvenir de la Malmaison, Francis Louvat, La Ville de St. Denis, Victor Verdier, fine; John Hopper, fine; Olivier Delhomme, Maurice Bernardin, Semiramis, Baronne Prevost, Souvenir d'Elise, Triomphe de Rennes, General Jacqueminot, Madame Hector Jacquin, Jules Margottin, Louis Van Houtte, Dr. Andry, Comtesse Cécile Chabillant, Auguste Mie; Maréchal Souchet, Baronne A. de Rothschild, Josephine Malton, a beautiful creamy rose; Queen Victoria, very fine indeed; Leopold Hausberg, fine; Maréchal Vaillant, Gloire de Dijon, Margaret St. Amand, General Washington, rough; Vicomte Vigier, La Reine, Madame Clémence Joigneaux, H. Laurentius, Anna de Diesbach, Madame Victor Verdier, Madame Fillion, Bernard Palissy, Madame Furtado, Le Rhône, Eliza Sauvage, fine; Xavier Oliho, Alfred Colomb, Caroline de Sansal, Pierre Notting, Céline Gonod, rough and almost coarse.

MR. CANT'S FIRST PRIZE, TWENTY-FOUR.—Charles Lefebvre, Madame Crapelet, Madlle. Margaret Dombrain, Xavier Oliho, Marie Baumann, the finest flower of this fine variety in the exhibition; Madame Bravy, Margaret St. Amand, President Mas, Madame Victor Verdier, Ruhens, Madame Fillion, Maurice Bernardin, John Hopper, Comtesse Chabillant, Triomphe de Rennes, William Griffiths, there was not one good example of this in the whole exhibition, though it was shown in very many stands; Le Rhône, Victor Verdier, Exposition de Brie, very fine; Madame Charles Wood, Madame Rivers, Duchesse de Morny, La Brillante.

In the amateur's sections Mr. Hedge, of Reed Hall, Colchester, took his old and well-kept place, and carried away the first prizes in the classes for 48, 36, and 24. The barriers were removed and the public rushed in just as we were making notes of the amateur collections, and we were compelled to quit without obtaining particulars of the awards throughout. As the Crystal Palace Company do not advertise their prize lists, we shall have to pass over the names of the winners of second and third positions, which we regret, because the amateurs are the life of rose shows, as they are the source of all power and improvement in the cultivation of the rose. Our occasional and much-valued correspondent, the Rev. E. N. Pochin, of Sibley Vicarage, Loughborough, took the first place in the class for 12 with as charming a dozen as was ever seen on an exhibition table. I saw one collection from an amateur who employed stonecrop for a surfacing to the boards with singular infelicity. I was about to turn up the card to see who was the innovator, but the old saw suddenly occurred to me, "if ignorance is bliss," &c. &c., and I passed on, and just had time to take the names of the following:—

MR. HEDGE'S FIRST PRIZE, FORTY-EIGHT.—Coupe d'Hébé, Sénateur Vaisse, Triomphe de Rennes, Madame Crapelet, Queen Victoria, Lord Clyde, L'Enfant Trouvé, Olivier Delhomme, Comtesse Chabillant, Madame Victor Verdier, Charles Rouillard, Marie Baumann, Louise Margottin, Charles Lefebvre, Ruhens, George Prince, Maréchal Niel, the best example of this rose in the show, colour clear, rich, and rather deep yellow; La Ville de St. Denis, Mrs. Rivers, Pierre Notting, Souvenir d'un Ami, Madame Charles Wood, Armida, Prince Léon, Devoniensis, Madame Boll, Caroline de Sansal, Alphonse Damaizin, Moiret, Souvenir de Count Cavour, Gloire de Dijon, Alfred Colomb, Souvenir d'Elize Varden, La Fontaine, Cloth-of-Gold, John Hopper, Madame Knorr, Charles Margottin, had; Auguste Mie; Madame de Camhacérés, Louise Darzens, Baron Gonella, Joan of Arc, Charles Lawson, Enfant de Lyon, Gloire de Santenay, Adam, Lord Macaulay.

MR. POCHIN'S FIRST PRIZE TWELVE.—Charles Lefebvre, Anna de Diesbach, Fisher Holmes, John Hopper, Madame Boll, Maréchal Niel, Xavier Oliho, Margaret St. Amand, Madame Victor Verdier, Prince Camille de Rohan, Souvenir d'un Ami, Madame Crapelet.

The collections of yellow roses and teas have been already remarked upon, and there is little more here to be said. The teas were so far unattractive that I made no note on them at all, though I should have done so if time had allowed; but from the stroke of twelve by the clock there is an end of reporting, the crush is too great, and possibly the reporters are by that time tired of their work, and desirous of change of occupation. There could be no question about the superiority of the yellow roses from Mr. Hedge; like all his flowers, they were in charming condition. To wait for the awards of the jurors in this case was needless; he was inevitably first. Mr. Bristowe, gardener to G. Orme, Esq., of Worthing, put up a boxful of yellow roses which were far from good, though it was not difficult to believe that the trees they were cut from are admirably grown; the flowers were rather spoiled by carriage than poor in the first instance, though had they been fresh Mr. Hedge's would have beaten them by a long stride. Mr. Hedge's varieties were Maréchal Niel, Janno of Smith, most beautiful; Triomphe de Rennes, L'Enfant Trouvé, Enfant de Lyon. Mr. Bristowe's were L'Enfant Trouvé, Eliza Sauvage, Gloire de Dijon, Solfaterre, Céline Forestier, Isabella Gray, Triomphe de Rennes, Cloth-of-Gold.

NEW ROSES.—In the first place in this section must be placed *Miss Ingram*, shown by Mr. C. Turner, of Slough, who has purchased the stock, and will be its distributor. This is globular, compact, thoroughly double, with a good centre, and stout petals, the colour pink and bluish in the

centre, shading to soft white outside; a counterpart of Mrs. Rivers, but a larger flower, and the plant, Mr. Ingram says, considerably harder in constitution. We are not rich in light roses; let us, therefore, give a hearty welcome to *Miss Ingram*. The following varieties were shown by Messrs. Paul and Son, *Princess Mary of Cambridge*, now well known as a charming rose of a class not much enriched by the importations of the past few years, for a majority of the new roses are crimson and carmine, and this is a fresh, clear, rosy pink, with shades of true rose colour. It has abundance of petals, is globular, and delicately finished, indispensable in every good collection. *Madame Moreau* is a fine crimson rose, substantial in build, and inclining always to be massive, a fine depth of colour, and in every respect first-rate. *Exposition de Brie*, a fine high-coloured rose. *King's Acre* has been fine in every instance in which it has been shown this year, illustrating a remark Mr. Pochin made to me, that "every rose has its season." Since it was first shown by Mr. Cranston, and made a sensation by its splendour, it has not looked so well till now; indeed, we began to question the character given to it. When good, as it is this season, it is a first-class rose. *Ville de Lyon*, apparently a fine showy rose, but in this case rather bleached and showing a bright yellow eye. *Monsieur Boncerne*, large imbricated, deep velvety purple, fine but flat, and showing an eye. *Elizabeth Vigneron*, large, rosy pink, good, if not coarse. *Charles Margottin*, bright carmine, large and showy, but thin. *John Grier*, *Achille Gonod*, thin; *Charles Rouillard*, Duke of Wellington, thin; *Madame Fillion*, Fisher Holmes, imbricated and camellia like, brilliant red, first-rate; *Madame Gustave Bonnet*, not well shown, but possibly a good rose; *Josephine Beauharnais*, delicate rose with silvery edges, the form good, a beautiful flower; *Madlle. Marie Rady*, red with whitish edges, doubtful; *Felix Genero*, fine; *Prince de Porcia*: this is described as carmine, but it probably approaches nearest to scarlet of any rose in cultivation, it is moreover good in character, though apparently thin. *Michel Bonnet*, a good model for a pancake, or for a mask for Polyphemus, the eye being very distinct. *Sœur Thecla*, thin; *Charles Verdier*, poor; *Alfred Colomb*, a fine rose, the form superb, and the petals thick and well packed, colour fiery red; likely to be a famous show rose for at least ten years to come. *Abel Grand*, not at all grand, the colour is a nice shade of silvery rose, and that is its only good quality; *Camille Bernardin*, fine in form and substance, colour bright red edged with white, first-rate. *La Tendresse*, beautiful. *Carl Coers*, a very had purple. *Antoine Ducher*, good; *Thorin*, fine; *Margaret Anaud*, first rate; *Madame Thérèse Levet*, *Xavier Oliho*, a most distinct, brilliant, and beautiful flower. *Madame Margottin*, Comte Litta, had; *Madlle. Margaret Dombrain*, quite second-rate, though pretty, the colour delicate bluish; *Maurice Bernardin*, one of the best of all roses, new or old; *Chevalier Nigra*, a beautiful flower of a fine rose colour, like Baron Gonella, but filled up in the centre in an almost conical form; *Gloire de Ducher*, deep purple, a good example of its class. *Belle Normande*, a pretty light rose coloured flower; *Jean Lambert*, large and full, neatly rolled up like Xavier Oliho, and very curious and pretty in bud, colour cerise shaded scarlet. *Comte Alphonse de Serenys*, red tinted purple, middling. *Dukè of Edinburgh*, like Exposition de Brie and Madame Moreau, a good rose, promising indeed to be quite first-rate. *Triomphe de Soissons*, not so good as Emotion. *Souvenir de William Wood*, a companion to Prince Camille de Rohan, but darker in colour; it has the fault of weak footstalks, and is a very superior flower. *Hippolyte Flandrin*, bright rose, commonplace; *Dr. Andry*, bright shaded red, good; *Souvenir de Bernardin de St. Pierre*, large, imbricated, velvety crimson, fine.

Many miscellaneous subjects were shown, but space cannot be afforded for detailed notices of them. Mr. Cowan, gardener to — Hutchinson, Esq., Croydon, presented a specimen of *Peristeria alata*, the Dove orchid, with seven spikes of flowers, standing six feet high, a fine example of an eminently interesting plant. Mr. Sleat put up a fine lot of Sir Charles Napier strawberry, some in pots and some gathered from the open ground; they were of great size and beautifully coloured. Messrs. James Carter and Co. made a beautiful group of tricolor-leaved and other geraniums, and received an extra prize for them. The varieties were *Prince of Wales*, *Princess of Wales*, *Oberon*, *Titania*, and others that have been described in former reports.

S. H.

EXHIBITION OF WINDOW FLOWERS, DEAN'S YARD, WESTMINSTER.

Some time ago a committee of gentlemen resolved on forming a society for the promotion of window gardening among the working classes in the united parishes of St. Margaret and St. John, Westminster, and on Friday the annual fête of the association was held in Great Dean's Yard. The specimens sent in for competition were ranged in two tastefully-constructed marquees in the enclosure, and when we consider the streets in which they were reared, and the deficiency in the supply of what are necessary in floriculture, light and air, they not only constituted a satisfactory evidence of the success of the society, but also a strong incentive to others to found similar associations in other districts of the metropolis. A fuchsia plant, which obtained the first prize in its class, was a conspicuous object of attraction. It was fully 6ft. high and 4ft. wide. The following is a list of the principal prizes, with the names of those to whom they were severally awarded:—Class 1.—Working Men and Women: Fuchsias, Alfred Fillwood, lamplighter, 2 Philip Street. Geraniums, Mrs. Ann Fillwood. Annuals, Mrs. Leigh, 5, Bowling Street. Class 2.—Domestic Servants: Fuchsias, Mary Ann Robinson, 3, Smith Square. Geraniums, Caroline Williams, 3, Smith Square. Class 3.—Children in parochial, national, infant, Sunday, and ragged schools: Fuchsias, Ellen Fillwood. Geraniums, G. H. Smith, 8, William Street. Annuals, Sophia Mullins, 21, New Peter Street. Prizes were also awarded in a class open to all persons, and in another, in which inmates of workhouse and hospital wards competed. For the latter division the rewards were some beautiful coloured prints, presented to the society by Miss Burdett Coutts. Among those present on the grounds were the Duke and Duchess of Argyll, Lord Ebury, the Dean of Westminster and Lady Augusta Stanley, Miss Stanley, and an unusually numerous company of other ladies and gentlemen. After the distribution of prizes, Lord Shaftesbury, who spoke from a rostrum in the centre of the enclosure, said that he had to congratulate alike the founders of the society and those who had followed in their footsteps. The real value of such a society as that might be estimated by any one who took the trouble to inspect the various districts of which the metropolis was composed. Its benefits were great as regarded its moral, religious, and physical effects. It was impossible to undertake the care of flowers without giving them a proper supply of light, air, and water, and those who devoted themselves to so refining

an occupation must necessarily make an application of its conditions to their own existence. He could tell them from his own experience that a high degree of civilization had been introduced into some regions of London by the culture of flowers, for with it came the admiration of God's works, and thanksgivings for His blessings. Everything which concerned plants and flowers was by an easy transition made applicable to ourselves. The children who had won prizes that day were deserving of all praise, but there were in the metropolis hundreds of thousands of others for whose religious and physical culture they should earnestly strive to provide.

GREENWICH PINK SHOW.

The Greenwich Amateur Floricultural Society's Pink show took place, on Monday last, at Orchard Hill, Greenwich. In the class for twelve, first, Mr. Stoer, of Eltham, Kent, with Maclean's Earnest, Marianne, Rev. George Jeans, Maclean's John Ball, Turner's Delicata, Elcho, Colchester Cardinal, Steer's Rose of Kent, Turner's Blondin, Turner's Constant, Beautiful, Maclean's Mary Ann. Second, Mr. R. Cronk, with Christabel, Miss, Nightingale, Delicata, Esop, Celestial, Blondin, John Ball, Mary Ann, Bertram, New Criterion, Volunteer, Amelia. Third, Mr. Gucran, of New Cross, with Eva, Mary Ann, Bianca, Miss Nightingale, Bertram, Delicata, Purple Perfection, Constance, Marianne, Beautiful, Rev. G. Jeans, Miss Stevens. Fourth, Mr. Rose, of New Cross, with Marianne, Bertram, Elcho, Purple Perfection, Constance, Mary Ann, Charles Williams, Earnest, Scarlet Gem, Kentish Volunteer, Beautiful, Picturata. There were several other collections in which we noticed beautiful examples of Mrs. Charles Williams, Maclean's Devico, Maclean's Evening Twilight, Star's Mrs. Gardens, Bonny Jean, Maclean's Kentish Volunteer, Maclean's Lizzie, Turner's Picturata, Maclean's Clara, Turner's Bianca, John Ball, Blondin, Delicata, Rev. G. Jeans, Elcho, Colchester Cardinal, Devico, Marian, Rose of Kent, Charles Williams, Beautiful. Seedlings were shown by Mr. Martin, the best being *Marksman* and *Hermil*. Mr. Howell brought forward an exceedingly pretty silver-edged tricolor-leaved geranium, and a capital lot of seedling varieties of shrubby calceolarias.

SNAILS AND SLUGS.

The long and almost uninterrupted prevalence of wet weather has this season encouraged snail and slug propagation to an almost unprecedented extent; and the unusual lowness of the temperature throughout the spring months having weakened and retarded plant growth, garden as well as field crops, and especially those of the brassica family, have been rendered more than ordinarily susceptible of injury and destruction from the ravages of these slimy herb-devouring members of the great mollusca group. Hence not only amateurs, but even experienced cultivators, have been driven to make use of all known remedies for removing or lessening what they have found to be an insurmountable destructive nuisance. A celebrated horticultural author has stated snail-hunting and slug-picking to have been a stereotyped recommendation since the days of Mascall. The intolligence of the present day prescribes for their complete annihilation the inexpensive easily-prepared application of caustic lime. Lime is, no doubt, one of the best specifics, although not by any means a sovereign remedy. The fact is, in the appliance of this, as well as in that of other modes employed for their extirpation, too little attention has been paid to the difference in the natural habits of the various kinds, which, in so far as they are generally and troublesomely prevalent, consist of six in all—namely, two species of snails and four of slugs:—

1. THE BROWNISH-SHELLED SNAIL (*Helix aspersa*), Muller.—The full-grown shells of this snail are larger than those of any of the other common native species, thin or delicate in texture, and generally of a dull lightish brown colour, with chocolate-brown bands, interrupted or marbled with very pale coloured streaks. Its habits are strictly nocturnal, seeking shade and shelter during the day in holes of walls, under stones, in box-wood edgings, &c. It is most abundant in places which have been long under cultivation, such as the vicinity of towns, near old residences, &c. It was formerly much in repute as a remedy for pulmonary affections; and is one of those kinds deemed edible in countries where snails are esteemed culinary delicacies.

2. THE VARIABLE-SHELLED SNAIL (*Helix nemoralis*), Linnæus.—Shells smaller, harder, and more globular than those of the last, remarkably variable in colouring, frequently very distinctly and beautifully banded, and sometimes of a uniform whitish or other colour, but never mottled nor marbled. A very common species, frequently most abundant where the preceding is rarest; compared with which it is somewhat less nocturnal in its habits, and more generally diffused over ground surfaces which afford little shelter except what is supplied by plants, clods, and small stones.

3. THE SMALL WHITISH SLUG (*Limax agrestis*), Muller.—This smallest lightish-brown species, the commonest and most voracious, as well as the most active, of the tribe, is abundant everywhere, in gardens, cultivated fields, and waste ground, sheltering in very clear and dry weather about the base of plants, under clods, stones, &c., and going abroad to feed at night, as well as in dull and rainy days.

4. THE LARGE GRAY SLUG (*Limax cinereus*), Muller.—Is the largest of our land molluscs, being often from five to six inches in length; of a dull brownish colour, mottled or spotted with black. It seeks shelter from drought and sunshine under stones, blocks of wood, large plants, &c., going out to feed an hour or two before nightfall, as well as throughout the day, when the weather is dull and moist, and is too well known to require further description.

5. THE LARGE BLACK SLUG (*Arion empiricorum*), Ferussac.—Is so well known as to need no description. It is more sluggish or slow in its movements than the last, which it, however, very much resembles in its other habits. And although generally jetty black, it is occasionally to be seen of various shades, some of them so light as to lead to its being considered a different species.

6. THE SMALL BLACKISH SLUG (*Arion hortensis*), Ferussac.—Also termed by gardeners the small blue and the yellow-bellied slug. The ordinary colour of this slug is a dull bluish black, but it varies much in different individuals, being in some approaching to white. In the young state it is whitish underneath, but it there often assumes a dull yellowish colour in older specimens, from which it has obtained one of the above names. It differs from all the preceding by being more underground in its habits, seldom appearing on the surface except in damp weather, and may frequently be seen in twos or threes, clustered and curved round the

stems of young brassica, and especially those of cauliflower, where they often remain till they have eaten the stems so far through as to kill the plants; and it is also not unfrequent on the tubers of garden-grown potatoes, even when they are three or four inches under the surface.

Newly slaked or caustic lime, as before mentioned, is an excellent snail and slug annihilator, but it must be applied when and so as it can reach them most effectually—that is, in the evenings, or after nightfall, when they are abroad and farthest from their sheltered haunts, or in dull days after rain-falls; for if applied during dry sunny days it will only have the effect of restricting them to their haunts till the lime loses its caustic or burning qualities, which it very soon does, and must consequently be renewed frequently if the weather is dull and showery. It is best also to apply it when the plants are dry, so as it will not adhere to their surface, and it should be spread on so thickly as to whiten the surface of the soil. But instances will occur when this whiteness will be deemed unsightly, and where night sprinklings of lime-water from the rose of a watering pan may be given in place with equally beneficial effects; and it is partially useful for clearing them from strawberry beds between the setting and ripening of the fruit. The undiluted liquid manure drainage of byres and stables is another very effectual agent in the destruction of snails and slugs, more especially of the latter; but it must be used with caution, for although it may be applied with impunity to the different kinds of brassicæ, it is too overpowering in its effects for many other plants. It is only such as these two liquid appliances by which No. 6 can be got at in its underground works of destruction, where it is secure against the reach and influence of any dry surface appliances.

Broken or chopped barley chaff scattered around plants is a good safeguard against both snails and slugs, as it adheres to and annoys them if they attempt to pass over it; but it is also unsightly, and so only suitable for defending special plants. When their depredations are dreaded in select flower beds, rockeries, or other places of moderately limited extent, they may be trapped by laying cabbage or lettuce leaves about, on which, by the aid of a lantern, they may be seen and gathered off an hour or two after dark. This is of all modes the most successful for dealing with the *Helix aspersa* (No. 1); and if preserved till next day these will prove highly acceptable feeding for both ducks and hens, which have no difficulty in breaking through the tender shells and extracting their, to them, highly acceptable contents.

Many kinds of singing birds and other wild fowl are good snail and slug destroyers; and it is curious to watch a common thrush in its laborious exertions of attempting to swallow a four or five-inch long *Limax cinereus* (No. 4), in which, if undisturbed, it generally perseveres till its efforts are crowned with success. Tame sea-gulls are great devourers of land as well as water molluscs, and one or two are frequently kept in large gardens for that purpose; and, with the same view, ducks and ducklings are often drafted from the poultry yard to the kitchen garden after showers or in mild evenings, the ducklings being usually preferred, in consequence of their light weight rendering them less injurious to young crops and newly dressed ground than their full-grown seniors. Passing a heavy roller over the ground when snails and slugs are abroad is sometimes done with the view of crushing them to death, but it is a mode only applicable to certain crops, and generally more suitable for those of the field than of the garden, although it may be performed when they are over-abundant on ornamental greens and grass lawns, but in no case should it be done on heavy soils when they are over-saturated, or it will be likely to bind and harden them too much. Dry soot and soot-water are other applications recommended for destroying slugs, but soot in any form is less deadly in its effects than lime, and for obvious reasons not so generally suitable.—*The Farmer*.

VEGETABLE MONSTROSITIES AND RACES.

The discussion recently excited by MM. Dareste and Sanson, as to whether monstrosities in the animal kingdom can give rise to distinct races, recalls to my mind teratological facts which appear to demonstrate that this may be the case in the vegetable world.

To avoid doubt, it may be well to explain that I use the word *monstrosity* in its ordinary botanical sense, that of notable departure from forms that are typical, or reputed to be such. There is a marked distinction between monstrosities incompatible with reproduction and those which do not impair the reproductive faculty. It is of the last only I have now to speak.

Well attested facts seem to me to place beyond doubt that considerable anomalies in the vegetable kingdom, that are usually classed amongst teratological facts, are faithfully transmitted from one generation to another, and become the salient characters of new races. Horticultural practice might have furnished a great number of such instances if they had been collected, and verified by experiment; but I shall only cite a few, because they are the only ones which I know to have been examined scientifically, and they suffice to establish the principle of hereditary transmission of anomalies, by sexual propagation through an indefinite series of generations.

The first fact of this sort shall be borrowed from Professor Göppert, of Breslau. A poppy exhibited the curious anomaly of the transformation of part of its stamens into carpels, from whence resulted a crown of secondary capsules round the normal and central capsule, whose development was complete. Many of the little additional capsules contained, as well as the normal capsule, perfect seeds, capable of reproducing the plant. In 1849, Professor Göppert, hearing that a field of these monstrous poppies existed a few miles from Breslau, caused to be sown in the following year a considerable quantity of seed taken designedly from the normal capsules, and almost all the plants springing from this seed exhibited to a greater or less extent the monstrosity of the preceding generation. I do not insist upon these facts, because observation of them was not carried to a sufficient extent, and it might be found that the number of generations was not large enough to conclude from them the stability of the anomaly.

This doubt does not affect the following case:—Cultivators of ferns know that these plants are very subject to variation, and that some of them exhibit, even in a wild state, veritable monstrosities in the conformation of their leaves. These monstrosities are much sought after by collectors, and are regarded as excellencies, for which a high price was paid. Now they are easily and abundantly procured by simply growing spores taken from the abnormal part of a fertile frond. When the frond has remained in a normal state, the spores give rise to normal plants, while those from monstrous parts of the same frond are sure to produce plants affected by same kinds of change. During many years that this method of propagation has

been employed, the transmission of the monstrosity has not been contradicted by experience.

Very considerable anomalies, which, even more than those just cited, may be called monstrosities, are observed in three species of edible gourds, plants which have been cultivated from time immemorial, and which have never been found in a wild state. These anomalies have the peculiarity of characterising races that are sharply divided and very persistent, and which maintain themselves, in spite of change of locality and climate, and partially resist crossing with other races of the same species. The date of their origin is unknown, and we cannot now tell under what influences they were formed; but as the species are all domestic, it is probable that some, if not all, have been produced by cultivation. Among them is a race of common gourds (*Cucurbita pepo*) in which the tendrils convert themselves into a sort of branches bearing leaves, flowers, and often fruits. There are also numerous races of the same species producing deformed fruits, warty, and particoloured, and which transmit their peculiarities with their seed so long as they are not modified by crossing.

A still more remarkable example is afforded by a small race of pumpkins, *C. maxima*, which we have received from China, and observed for many years in the Museum. It differs from the typical form of the species by the ovary and the fruit being entirely free, and the tube of the calyx being reduced to a sort of disk (*plateau*), serving for the support of the carpels; notwithstanding, the complete adhesion of the ovary to the tube of the calyx is stated by authors to be an essential character of the family of the Cucurbitaceæ. This example shows how great the extent of variation may be, and what fixity they may acquire when once produced.

The next fact of which I have to speak is quite recent, and has already been brought before the Academy by Dr. Godron, Professor of Botany, at Nancy. In 1861 M. Godron found, in a crop of *Datura tatula*, a species with very spiny fruit, a single individual, in which the capsule was perfectly smooth, and unarmed. Seeds taken from this capsule gave, in 1862, a batch of plants, all of which reproduced the peculiarities of the individual from which they sprang. From their seed grew a third generation, similarly smooth, and in 1865 and 1866 I saw at the Museum the fourth and fifth generation of this new race, in all more than 100 individuals, not one of which manifested the least tendency to reproduce the spinous character of the species. Crossed with this last by M. Godron himself, the unarmed race produced mule plants, which in the succeeding generation returned to the spiny form, and the unarmed form, being, in fact, genuine hybrids, endowed with fertility. M. Godron, from these facts, refers to one species, the *Datura Stramonium*, *D. levis* (of Bertoloni, not of Linnaeus), and *D. tatula*, three constant forms previously regarded as good species, and adding to it *D. tatula inermis*, discovered by himself, and, so to speak, born under his eyes. These four distinct forms have arisen by variation from a single type, not one of them wanting in any character assignable to true species.

Here a point presents itself, to which I would call the attention of all who believe in the mutability of specific forms, and who attribute the origin of actual species to simple modifications of more ancient species. Most of these observers admit that such modifications have been produced with exceeding slowness through insensible gradations, so that thousands of generations may have been required to transform one species into a neighbouring species. We know not what may have happened in the course of ages; but experience and observation teach us that at the actual epoch of anomalies, whether slight or profound, the alterations in what we, perhaps, arbitrarily, call *specific types*—the *monstrosities*, in fact, whether they are of a transitory and individual character, or whether they give rise to new races, persistent and uniform, through an indefinite number of individuals—are produced abruptly, and without any transitive forms between them and the normal form. A new race is born completely formed, and the first individual representing it exhibits the characters of the generations that will succeed if the variation is preserved. New modifications may be added to the first one, and occasion a subdivision into primary and secondary races; but these appear with the same suddenness as the first variation did. I am not defending the doctrine of evolution. I state merely that the biological phenomena of one epoch do not justify in any way the hypothesis of an insensible degradation of ancient forms, and the necessity for millions of years in order to change the physiognomy of species. Judging from what we know, their transformations, if they have taken place, may have been effected in a much smaller lapse of time than is supposed. There may be alternations in the life of nature, and periods of immobility, apparent or real, may succeed other periods of rapid transformation, during which that which was previously exceptional and abnormal becomes a portion of the regular order of things. And we must not forget that time is to us a succession of phenomena, and that whether the phenomena succeed each other quickly or slowly, it is all one for the doctrine of evolution. In either case the principle of continuity is not assailed.—CH. NAUDIN, from *Comptes Rendus* in July No. of the "Intellectual Observer."

COWPER'S TOMB.—"I come from East Dereham, the paradise of England, sir; in the church there Cowper, the poet, was buried, and my father helped to dig his grave; East Dereham, in the county of Norfolk, the paradise of the world, sir." Such was the exclamation of a good and gone old friend of ours; and as the assertion was hammered into our ears at least three hundred and sixty-five times a year (more or less) it will readily be imagined that we expected to find something at least picturesque, if not absolutely Arcadian. But fancy our astonishment upon arriving at "the paradise of the world," and finding the place a veritable Cottenham, from which Mark Tapley would have retreated. Nothing in the likeness of Eden could we discover, and not till the bells were rung next morning, upon the anniversary of our gracious Queen's coronation, could we be brought to believe that we had arrived at East Dereham at all. However, in the course of the day ample amends were made by a friend of the old worthy above named; we visited Cowper's resting-place, and this in itself was sufficient to atone for any shortcomings of East Dereham, "the paradise of the world." Some of our readers will perhaps be interested to learn that the tomb of the bard is very plain and simple. Upon the top is the Bible, and leaning against it is the immortal work of the "The Task." Over both books is a leaf, which appears to be a species of large fern. Cambridge Independent Press.

* * * SUBSCRIBERS requiring back Numbers or Parts of the GARDENER'S MAGAZINE to complete sets, are requested to order them through their bookseller, who can always procure them from the London publisher. At the same time, instructions should be given that in case some of the numbers required are out of print, as many as can be had should be sent, it being a rule with the book collectors, if they cannot obtain all the numbers wanted not to take any, saying they are "out of print."

WIRE-FENCING FOR PLANTATIONS.

Wire-fencing at the present time is, perhaps, more used than any other kind of fencing, and, in particular situations, is a very neat and efficient fence when kept properly strained; but how often it is met with in a very different form—wires slack, posts half drawn over—in short, "presenting an appearance more like the ruins of some gigantic spider's web than anything else." The fact is, a wire fence, if not kept properly strained, is the most miserable fence extant.

The common method of erecting wire fences, with wooden straining, posts, on which the wires are fastened, must always prove an annoyance, let the wire be never so well put up, by the wood contracting and decaying. Even the best hard-tempered wire always yields more or less to the strain through length of time, and though the wires can be loosened and tightened, yet it can never prove satisfactory. There are several improved appliances

Fig. 1.

for straining and keeping the wires in proper tension, such as the patented straining pillars, descriptions of which I have at former times seen advertised in the pages of *The Farmer*, and no doubt, as the advantages of such become better known, they will be more generally adopted. The first cost, in many cases, is a drawback; but if the fence is intended to be permanent, it will prove the most effectual and cheapest method in the long-run. No doubt there are many other contrivances more or less useful in their own way. Fig 1 is a form of straining-post which I have used, and answers the purpose very well, and is not very expensive; and as it can be easily constructed by any handy blacksmith, the following outline of its construction may perhaps prove useful to some of your readers:—

The straining-post is formed of 1½ inch square bar iron, 4 feet long—if for six-wire fence, to stand 3½ feet high—fastened into a stone block in the usual way; there is no stay required in intermediate stretches, as one stretch supports the other. The appliances for straining the wires, fig. 2, are two winders (w) turning in two iron plates (p), which are fastened with two bolts (b), one on each side of the iron bar (B). The plates are 7½

Fig. 2.

inches long, by 1½ inches broad, by ¾ inch thick, in the form of fig 3. The winders are formed of inch-round iron 3½ inches long, ¼ of an inch of the end of each being formed square, projecting on one side of the plates, for the purpose of being turned by a key when straining the wires. There are two iron pins inserted in the winder, cross to each other, and close to the inside of each of the plates. They project about ¼ of an inch on each

Fig. 3.

side of the winder, and serve to keep the winder in its place, and also to hold the wire, the end of which is inserted in a hole in the winder, at every quarter-turn, by a piece of wire which is put through the small hole in the plates near the winder.

It will be seen that each straining-post serves to strain two stretches, one on each side of the straining-post. As 200 yards is not too much for a stretch, where the line of fence is straight, one straining-post will strain 400 yards. Where rigid economy in the first cost is an object, and where there is a long line of fence, a wooden post can be erected between the straining-posts for fastening the wires to. Under any circumstances, however, it would be better to use an iron post, as it will not cost much more, being only a plain bar of iron, no winders being required for the intermediate posts.

Fig. 4.

Fig. 4 is another form of winder, formed with a bolt and nut for fastening into a wooden post. In using hard-tempered wire it will be found an advantage to soften a foot or two of the ends of the wire by heating, which takes the temper out of it, and renders it more pliable, and not so liable to break when winding or unwinding it.—JAMES KAY, *Eden Place, Rothsay, in "The Farmer."*

OBSERVATIONS ON WATERING PLANTS.

The utility of this practice, that is, of constantly pouring large quantities on to the roots of plants in beds, and elsewhere planted in the grounds during dry weather, admits of some inquiry, because among amateur horticulturists it is considered one of the greatest essentials for promoting the growth of vegetation. However necessary the supply of water may be to plants out of doors during dry seasons, yet, in my opinion, the use of it is too frequently urged by amateurs without due consideration as to the consequences which must follow from an excess. I have for some years past carefully contrasted the results of the constant use and the occasional use of water to bedding plants during the prevalence of dry weather, by observing the effects in two gardens adjoining each other, and belonging to separate proprietors. In one of them there was every facility afforded for providing the garden with a liberal supply of water, and the proprietor of the same insisted on his gardener using it freely, which order was constantly adhered to. Not so favoured was the other adjoining garden. The water required for their ordinary use had to be fetched some distance. Altogether the supply was very limited during dry weather, yet withal the bedding plants were on a par as regards continuance and quality of bloom. We must admit that the water, as sprinkled on the soil of an evening, imparted a very enjoyable freshness to those who promenade the garden. But the object we have in view is to show that the quantity of water poured on beds by many persons does not benefit the plants to the extent that many suppose. You, of course, expect me to give my reasons for such an assertion.

It is thus. We will presume that two plants of the same species are cultivated in the one garden, but subject to the influences of different conditions. For instance, take the common wallflowers: one shall be grown in a bed or border, and supplied with water in the usual way; the other may be planted or self-sown on the top of a wall, where it never receives any moisture beyond what the dews or rains afford. Yet during very hot or dry weather the plant on the wall does not show any indications of suffering from the effects of drought, while that in the border, which is in the habit of being watered in the regular way, will soon exhibit signs of drought by flagging if the watering is discontinued, especially after the plant has been subjected to the treatment for some time. To what, then, are we to trace these differences in the behaviour of the two plants? Why, that the organs of the plants growing on the wall have so developed themselves as to accommodate their structure to the circumstances which surround them; for example, the pores of the leaves have become so contracted as not to be so susceptible of adverse changes of weather. Not so with the plant in the border; owing to the very liberal treatment afforded it, its organs collapse at the slightest changes that are not favourable to luxuriant growth. I have in sight of me now while writing several kinds of plants thriving on the top of a wall that have not had a drop of water given them this season beyond that afforded by the elements, and yet their foliage is equal with the same kinds of plants in the ground; though there is this difference, that those growing on the wall are dwarfer compared with the others. Having said thus much, we maintain that the time spent by some in watering is a waste of labour. There can be no question but cleansing the leaves of plants in beds or borders with a syringe, or a rose fixed to a garden engine, is very beneficial, far more so than the often repeated application of it to the roots.

We do not say that watering is not requisite to newly planted beds—decidedly they require it, but not in such large doses as some persons apply it. When plants are established, we believe the roots will search for and find the required nourishment, provided they are planted in good soil. In preparing our flower-beds for the reception of the plants, I do not think, as a rule, that we give so much attention to the preparation of the soil as we should, by depositing some little depth beneath the surface materials that would afford the roots plenty of nourishment during hot weather. Such a practice would obviate the frequent use of the watering-pot during seasons of drought.

JOHN F. McELROY.

A PACKET OF ODDS AND ENDS.

EARTHING CELERY.

Being somewhat alive to the wants of a gentleman's table, so far as the garden is concerned, I find it to my own benefit to be always on the alert, and to keep a sharp look-out for every good thing that may turn up as likely to be useful, and also to prove by practice, on a limited scale, the recommendations of others when they favour us with any new method of culture; for I am not one of those who, having read an article detailing any thing new in practice, put it aside as useless because it is new; I prefer to ascertain if it is applicable to my own case, and if it is I adopt it; but if I do not find it answer, I say it is not to be universally recommended. This is a far more reasonable plan than to throw aside with disdain, after a mere perusal, any article that bears upon the face of it some amount of practical information, although it may not exactly suit our own preformed notions. But this is not writing about earthing celery; so I will tell you of a plan which I adopted last year, with perfect success to myself and to all concerned. But mind, I do not say there is anything new in it; for all I know, it may be as old as the hills, for we have high authority for the doctrine that there is nothing new under the sun. I will not presume therefore that this is a new idea, but at all events it is new to me, and a force of circumstances brought me to adopt it. Finding last autumn that I had planted out larger breadths of celery than I had previously done, I could foresee that I should have sufficient to carry the supply on until early spring, which a limited space had previously prevented me from securing. The supply being thus increased, my next anxiety was how to best secure its keeping in a soil that is rather retentive of moisture during winter. After a day or two's consideration, I decided that instead of earthing up, as I had usually done during the months of September and October, all the celery as it grew in height, I would not put any earth to those rows that I required to come into use about the beginning of February, but instead of putting earth round the stems I would tie each one up loosely with a piece of matting. This I did, adding another tie above the other about the middle of October, and on a dry day in the beginning of the second week of last November, just before the few days' frost we had after that time, the whole body of earth was put to it at one time, so that instead of repeated applications of earthing, there was only one. The day it was done was bright and clear, and the plants perfectly dry; and the result was that after such a severe winter the last row taken up at the end of March was equal to the first, and to find a root that was getting rotten at the heart was the exception. Such a result I never had before, because I had hitherto earthed up by piecemeal, but I will never do so again for late celery; as where half

of the crop is often lost by the old method, ninety-five per cent. is secured by late earthing. The rationale of this is simple enough; for all the time celery retains its natural colour it is not affected by moisture, but once bleached it and surrounded with earth, or indeed any thing that will retain moisture, it is susceptible at once of all the ills attending reduced vigour, exclusion of light, and the action of damp. By late earthing we retain it in its natural state quite two months later, and practically we add that much to its time of keeping.

CONNING'S RELIANCE BROCCOLI.

Those of our readers who desire a good late May broccoli may depend upon this variety, if they can secure it true. It is perfectly hardy, producing fine large heads from the middle up to the end of May. I saw it when visiting Mr. Record, of Hawkhurst, on May the 11th. His plants were just then showing their heads.

STADTHOLDER CAULIFLOWER.

Have any of our readers grown this variety for summer use? I saw it last year when visiting a friend, at a place near Wimbledon Common, in superb condition. It was August when I saw it, and the heads were as compact and white as any I ever saw in June. It is of neat habit, being close and compact, evidently a first-class variety to come in before the Walcheren.

GRUBS AT THE GREENS, AND HOW TO CATCH THEM.

When you have planted a piece of cabbage, and fancy you shall be troubled with the black grub, cut a few sods of fresh green turf about a foot square, and place them amongst the plants grass upwards. If there are any grubs, they will congregate under these turf sods, from whence you must remove them by going round early every morning. Turn the turf on one side, and where it had lain there will be the grubs, if there are any about. Pick them up, and put them in some vessel, and as soon as possible destroy them. I learnt this rub early one morning last May when on my journey of inspection. I wished to catch an early train for Hastings, and on my way to the station I passed by a cottager's garden. The cottager had just risen, and before he went to his work was turning over some green sods amongst some cabbage plants; and I could see under each one he picked up something, and consigned it to a tin box. I stood for some seconds watching his movements, and then as I felt I should like to know more about what he was gathering up from beneath these sods, I boldly asked him; and he not only told me what he was doing, but he showed me the results of his morning's gatherings by exposing to my view two or three dozen of those monster grubs. The cottager assured me it was his only means of saving his crops; in fact, he had adopted it for years, and while they had a fresh turf to go to, he assured me, they would not disturb a plant. Since then I have adopted the same plan myself, and I have found it to answer admirably.

J. C. CLARKE.

RAISING PETUNIAS FROM SEED.

The cultivation of the genus is so simple, and requires so little of what may be called "tact," as to place them within the command of the smallest grower. If healthy plants are purchased in the spring, they may be increased to any extent through the summer months, by inserting cuttings under a small hand-glass upon any shaded border; and but few plants may be kept with greater ease in the sitting-room window. But it is to their culture from seed we intend to direct our remarks; and for this purpose a good-sized well-ventilated melon-pit or greenhouse is necessary; it may be done in either, though we think the pit preferable, because the plants, naturally impatient of heat, may here have a larger proportion and be in more immediate contact with the fresh air, and for the greater facility of covering, uncovering, shading, watering, &c. A difficulty is generally experienced in procuring sound well-ripened seed; this is attributable to our variable and often dull wet summer. The plants being natives of the clear bright sunny regions of South America, have not the natural and necessary space of dry weather either to fertilize or, when that happens, to mature their seeds; hence the necessity of a pit or some such protection in the blooming season. It is well known to all acquainted with the laws which govern the vegetable productions of the earth, that a certain amount and continuance of dryness in the surrounding atmosphere are essentially requisite to enable the plant to fully develop its generative powers; and the want of these is the frequent cause of failure in the production of good seed, and so of crops. This is perhaps beyond removal in relation to things of extent requiring the open air; but with subjects like the present, which are portable at pleasure, we see no difficulty in remedying this defect of our climate.

We will suppose a collection to be formed of strong healthy plants, and containing some of the best sorts. About the beginning of April they should be placed in large pots, with any light rich soil, such as a mixture of leaf-mould, loam, and decayed hotbed-manure; there should be sufficient of this earth in the pots to sustain the plants throughout the following summer, without being again shifted. Petunias frequently commence blooming about the beginning of May; the first flowers may be taken advantage of to decorate the greenhouse or other place, as it is not these that are to be depended on for the production of seed, but such as appear about the commencement of the settled weather of June or July; at this time the plants should be taken to the pits, the better to protect the flowers from occasional showers and other moisture; in this situation they require an abundant supply of water and air, with free exposure to bright sunshine so long as they will bear it, which they will do to any extent (if regularly watered) until the roots have entirely filled the pots. Should it happen that cloudy weather prevails, advantage of every gleam of sunshine should be taken to assist the plants by artificial fertilizing; but in anything like the average summer weather this will not be required, as the plants themselves, assisted by insects, will perform the operation; after the seed is set, it will only be necessary to keep the head of the plant dry, that moisture may not lodge in the capsule, and so destroy it; each pod of seed should be gathered as it becomes ripe, and the whole kept in the usual way until the season for sowing, which we recommend to be the early part of March; a slight hotbed, such as is usually employed at this part of the year for raising tender annuals, will be necessary on which to sow the seed; and as soon as they are large enough to handle, let them be potted singly into small pots, continuing them in the frame until grown sufficiently to bear removal to the greenhouse; here, with the usual attention to repotting, &c., they will produce flowers almost as early as mature plants, and according as any improvement or degeneration is observable they should be preserved or rejected—the best to be increased by cuttings, which root readily at any time in sandy mould on a gentle bottom-heat, and the remaining portion may be turned into the beds of the flower-garden. We have generally observed the white and pale-coloured varieties exhibit a much less tendency to produce other varieties than those of a deeper shade.

Calendar.

WORK FOR WEEK COMMENCING JULY 6.

Kitchen Garden and Frame Ground.

KITCHEN GARDEN.—When early crops are coming off, clear the ground and dig it over at once; it is a folly to wait for the last handful of peas or beans. As soon as the rows cease to be profitable, destroy them, and clear the ground. Dig deep, that the heavy rains now to be expected may sink deep, and plant out Brussels sprouts, green collards, kale, savoy, cabbages, broccoli, &c. If the plants are crowded in the seed-bed, it is best to get them out at once. Have all ready, and in the evening put out as many rows as possible, and give a little water to every plant. Next morning lay a few houghs or mats over them to shade off the sun, and the next evening get out more, till the planting is finished. This is better than waiting for rain, which may be so heavy as to render the ground unfit to be trodden on, and, if succeeded immediately by heat, the plants will flag as much as if put out in dry weather, whereas, being already in the ground, the smallest shower benefits them. Seed-beds for winter spinach should now be made up and well manured, and the seed got in without delay. In gathering French and runner beans, take all or none. If seed is desired, leave a row untouched. Never take green pods and seeds from the same plants. Take up onions, shallots, and garlic, as they ripen, and store for winter. Give asparagus beds plenty of liquid manure, and use the grass mowings from the lawn as mulchings to prevent the soil from cracking. Earth-up celery for early use, but the rows that are not forward must be kept open and well watered, as the plants grow very slowly after being earthed up, the object of the earthing being to blanch it only. Also plant out the main crop of celery as soon as the ground can be got ready. Cut down artichokes. Hoe between all growing crops, and especially between potatoes. Top runners, and keep them well staked, but very tall sticks are not at all necessary, as they are only the more liable to be blown over by gusts of wind. Sow the last succession of runners and French beans; also lettuce, endive, Stadtholder and Mitchell's cauliflower, radish, small salads, spinach, peas, and turnips. Land lying high and dry may be planted with potatoes now, for use early next spring.

PEAS may be sown this month for late supplies, and at this season it is as well to sow early as well as late sorts. Bedman's Imperial and Knight's Dwarf Marrow are good peas to sow the first week this month, for a supply very late in the season; but Sutton's Emperor, Sangster's No. 1, Advancer, and other of the earliest sorts, often prove useful, and are soon cleared off the ground. The best way to grow peas now is in trenches. Take out the trench a depth of two feet, lay at the bottom six inches of rich half-rotten dung, then fill up to within nine inches of the surface, and tread over. Then sow, and cover with two inches of mould, and bank up the sides of the trench, so that the peas will grow in a sunk alley of about six or eight inches depth. At each end of the alley, close it in with a spadeful of earth, so as to make a trough of it. As soon as the peas are up, sprinkle them plentifully with soot or wood-ashes; stick directly, and then every evening in dry weather you can fill the alley with water, alternating twice a week with manure-water, and the crop will come wonderfully fine. This plan is the one we always adopt after the beginning of June, and we have for years had healthy rows of peas, and abundance of produce, when elsewhere the heat has turned them yellow before their time, and the gathering has scarcely paid for the seed. The method is not so troublesome as it appears, for the filling the trench with water is but a few minutes' work, and being sunk and closed at the ends, there is not a drop wasted.

CUCUMBERS.—Keep liberally watered, and train and thin as necessary, to prevent crowding. They will take almost any quantity of liquid manure if in a good state at the roots.

Flower Garden.

FLOWER GARDEN.—Budding is the most important operation this month. After heavy rains is the best time, and the operation should be performed at dawn or after sunset; but early morning is the best, as the sap then flows freely. The stocks should be vigorous, and if the weather continues dry, and if the sap flows slowly, a drenching of liquid manure or plain water for two or three nights in succession will prepare them, without waiting for rain. Cuttings of all kinds may now be struck out of doors; Antirrhinums, Phloxes, Pentstemons, Alyssums, Dielytras, &c., and cuttings of Laurels, Aucubas, and other shrubs, must be struck in the shade; but Geranium cuttings should be struck in the full sun, and the sooner they are got in the better plants will they make to stand the winter. Where long ripe branches of Geraniums can be spared, they are better than soft shoots; and, if pinched for time, strike a lot of such ripe branches in five-inch pots, half a dozen in a pot, put all round, and they need not be potted separately till spring, when started for hedging out. Dahlias want special attention now as they come into bloom; earwigs are very destructive to them, and must be trapped with beanstalks, or a handful of hay may be stuffed into an empty flower-pot and put on a stake, and the vermin shaken out into salt and water every morning. Another lot of Chrysanthemums should be struck this month, under hand-glasses, to make dwarf plants for the window and greenhouse in autumn. The pompones are the best for this purpose, and they may be stopped till the middle of August, to keep them dwarf and bushy. Train out Dahlias neatly, but do not cut them severely, for the loss of foliage only weakens the plant. Put in cuttings of scarlet Geraniums in the full sun, either in a sandy border or in pots half filled with crocks, to be potted singly as soon as rooted. Get strong plants of Chrysanthemums into their places in the borders, so that the heavy rains this month may establish them. Layer Pinks, Carnations, and Picotees, and put pipings of the same into a gentle bottom-heat. Another lot of annuals may be sown early in the month, to keep up the gaiety of the borders. Bud Roses during cool moist weather.

DAHLIAS must be labourled as to disbudding and tying, because every variety has its own peculiar style of growth. Disbud freely all soft-eyed varieties, but hard-eyed kinds allow to open all the blooms they make till they come good.

EVERGREENS and shrubs of the free-growing kinds may be propagated from this time to the end of August; cuttings put in in a shady place will root immediately. Prepare now to plant evergreens, which move well from the end of July to the end of September. In new ground this is the

best season to plant them, but in established gardens the places intended for them are generally occupied with summer flowers.

HEDGES of all kinds, except holly, should now be clipped in. Hedges of large-leaved trees—such as laurel, aucubas, &c.—ought to be cut back with a knife, as the shears will spoil their appearance for the whole season.

PINKS to be propagated from pipings, layers, or cuttings. The last is the simplest, most certain, and therefore the best method.

RHODODENDRONS and other hardy Anaricans may be layered now. Beds of Americans much exposed to the sun will be benefited by being mulched with moss.

WORK OF THE SEASON.—WATERING.—Bedding plants that were put out early now look worse than those that were put out late. We shall probably have plenty of rain this month, indeed, July is a wet month usually. But as it is also a hot month, a few remarks on watering may be useful. This matter of watering is one much less understood than it should be; but the more it is understood the lighter becomes the labour. As a rule, water should never be given until the further withholding of it would be detrimental to the plants. *Habitual* watering does, in the majority of cases, more harm than good. Plants left to battle with drought send their roots down deep in search of moisture, and when rain does come, they benefit more by it than those that have regular waterings all along. If the ground is dug deeply, and kept in good heart, plants that have once got established will bear drought for almost any length of time; but things lately planted, and that have not had time to "get hold," must be kept supplied, or their beauty may vanish for half the season. Succulent vegetables, too, which ought to be kept growing quick, must have abundance; and of course, plants in pots must, of necessity, have sufficient. There are two important points to be attended to in giving water—one is to expose the water to the sun before using it, to render it soft and warm; and the other is to give a thorough soaking at once, sufficient to keep the ground moist for a week. Supposing the supply to be limited, but regular, the best way of economizing both water and time is to take the garden piece by piece, watering each piece thoroughly every evening, and then beginning again as at first. Surface sprinklings bring the roots to the surface in search of the moisture, which, when they reach it, is insufficient to nourish them; but, on the contrary, causes exhaustion, by inducing the growth of fibres within reach of the burning rays of the sun. Plants in pots, in windows, and on gravel paths, are very much tried by the heating action of the sun, and to keep their roots cool, it is advisable to drop the pots into larger ones, and fill between the two with moss. This is the proper way to use ornamental pots, and the dressing of moss may be made to hide the inside pot, which contains the plant, by arranging it neatly over the surface of the soil.

Fruit Garden and Orchard House.

STRAWBERRIES.—Runners of strawberries struck in pots may now be cut off, and the plants shifted into a size larger, or turned out into beds. Beds made now have the best chance of becoming strong before winter, to bear abundantly next year. Strawberry-beds now want special attention. Strong-rooted runners should be taken off to form new plantations, and be pricked out into well-manured beds, pretty close together, to strengthen, preparatory to making new beds in September; or they may be laid in small pots, with a stone or peg to fix them, and will root directly. After three years, strawberry-beds cease to pay, and should be broken up and the ground trenched for winter crops.

STONE FRUITS.—Tie in and train as needful, and use the syringe to wall trees if the weather should be dry, and especially with east winds. Continue to bud stone fruit-trees, for orchard and pot culture. Thin out weak spray on all bush-fruits, and foreright shoots on wall-fruits. Maiden trees intended to be trained should be stopped, to make them break into side-shoots, as a whole season's growth is thus saved.

BUSH FRUITS.—Keep gooseberry and currant bushes open in the centre, and leave on the hush-fruits only as much wood as will bear a fine crop next season. Cuttings of gooseberries and currants may be struck now in a moist shady border, and if sufficient canes were not got in last winter, the deficiency may now be made good, and a season be saved. Mulch raspberries with half-rotten dung.

Greenhouse and Conservatory.

GREENHOUSE.—Shift all greenhouse plants required for late blooming, and grow them on to a good size before allowing them to blossom. Cinerarias for winter blooming must have good culture and shifts as required, and Camellias may be shifted if necessary; but if well potted in the first instance, they will flourish in the same pots for three seasons in succession, and to overpot them is to do them injury, from which they may never recover. Ericas generally require to be pruned and cleared of seed-pods and dead flowers. Put out all the Ventricasas in the open air in a north aspect, and shelter with spare lights during heavy rain. All those with woolly leaves to be put in cold pits, and kept shaded at midday. Any not shifted in the spring cut in at once, and as soon as they break repot them. Repot Icoschenaultias. Every kind of hard-wooded plants may be repotted now if out of bloom.

AZALEAS to be prepared for ripening their wood by giving more air. Put out the earliest in a shady place.

CAMELLIAS.—Treat the same as azaleas, and shift any that require it. Their roots may be refreshed without giving larger pots by turning out the ball, removing some of the stuff from it, and making it up again with fresh compost. Pot firm.

CINERARIAS to be propagated from suckers; put in round the sides of the pots in very sandy compost, and keep close for a week. Sow for seedling plants.

CONSERVATORY to have plenty of air night and day, and abundance of water for all growing plants, overhead as well as at the roots. Neglect of watering now will hereafter show sad results, especially among soft-wooded and liliaceous plants.

PELAGONIUMS newly cut down to be kept pretty dry till they break, then to be potted in small pots. Pelargoniums done blooming must be turned out, but with the pots plunged in tan or ashes, and the plants sheltered. After a week's exposure, cut them in to the first or second eye at the bottom of each shoot, and place them in a cold pit to make their new growth. They must now for some time be kept from growing rapidly, and have but little water. When they have broken well, they must be repotted into the smallest pots their roots can be got into, and all the old soil must be shaken off, and the roots moderately thinned.

Stove and Orchid House.

STOVE.—Achimenes and Clerodendrons require weak liquid manure to keep them in full vigour and beauty; shade at midday, and keep up a moist heat. *Globo Amaranthus* must have a moist heat of 75°, and be near the glass. If not all potted, pot at once in 48 and 32 size, with such a compost. *Ixoras* done blooming to be out in close and placed on a bark bed to break afresh. See that the plants for winter blooming are doing well, and pay especial attention to *Euphorbia jacquiniiflora* and *Poinsettia pulcherrima*. Give air at every favourable opportunity; plants newly potted to have very moderate supplies of water at the root, but to be aided with a moist warm atmosphere.

ORCHID HOUSE.—Orchids that have finished their growth should now have such attention as is required to get the pseudo-bulbs well-ripened. Many of the large specimens will be found to require sponging all over, and this had best be done at the first opportunity, and in the present lull of work there is a fair chance of its being done effectually. More air should be given now among orchids, and to allow of a freer ventilation, put all the small and growing plants at one end of the house, where they can be kept close. *Stanhopeas* are about to commence their seasonal growth, which is a good time to repot them. As a rule, they do best in baskets, both because of their habit of growth and the downward direction of their flowers. They should have plenty of root-room, in shallow baskets filled with chopped moss, and after the shift to have very little water at the root till they grow freely, but liberal heat and atmospheric moisture. As soon as they begin to grow, water at the root freely, and keep them growing briskly till they have formed their pseudo-bulbs, and then keep nearly dry till they show flower. A prolonged rest is most essential to their welfare. To get up good specimens, put them in large baskets, in which they may continue several years without shifting. There need be no fire-heat in either house this month, unless we have a long period of dull, cold weather, in which case keep up the temperature by artificial means; but, as a rule, a judicious system of ventilating and shutting up will ensure a proper temperature for Indians and Mexicans alike, and better than by the aid of fire-heat. Temperature of East-India house, and for growing plants, 70° to 75° by night, 75° to 85° by day, with a rise to 90° with sun-heat. Mexican house, 65° to 70° by night, 70° to 85° by day.

ORCHIDS THAT MAY BE IN BLOOM IN JULY.—*Aerides affine*, odoratum, roseum, crispum, crispum v. *Lindleyanum*, crispum v. *pallidum*, crispum v. *Warneri*, *Fieldingi*, *maculosum*, *maculosum* v. *Schraëleri*, *Morlandi*, *nobile*, odoratum, v. *cornutum*, *quinquevulnerum*, *quinquevulnerum* v. *album*, *suavissimum*, *Veitbii*; *Acineta Barkerii*; *Angoveum caudatum*; *Anguloa Clowesii*, *Clowesii macrantha*, *uniflora*, *virginalis*; *Arpophyllum cardinale*; *Barkeria melanocaulon*, *spectabilis*; *Bobophyllum Henshalli*; *Brassia Lanceana*, *Lawrenceana*, *Wrayii*, *Broughtonia sanguinea*; *Calanthe Dominici*, *fureata*, *masuca*, *veratrifolia*; *Cattleya Aclandiae*, *amabilis*, *candida*, *citrina*, *crispa*, *crispa* v. *superba*, *Harrisoniae*, *Harrisoniae violacea*, *labiata-pieta*, *Lemoniana*, *Mossii*, *Morlandii*, *Sehilleriana*, *superba*, *violacea*, *Wagnerii*; *Cologyne Lowii*; *Coryanthes macrantha*, *macrantha maculata*; *Cynoches barbatus*, *chlorochilum*, *Loddigesii*, *ventricosum*; *Cymbidium pendulum*; *Cypripedium barbatus grandiflorum*, *Lowii*; *Dendrobium alba sanguineum*, *calceolaria*, *cretaceum*, *sanguinolentum*; *Dendrochilum filiforme*, *glumaceum*; *Epidendrum alatum majus*, *cinnabarinum*, *maculatum grandiflorum*, *Phœnicum*, *verrucosum*, *vitellinum majus*; *Galeandra Bauerii*, *cristata*, *Huntleya*, *melegaris*; *Lelia Brysiana*, *elegans* v. *Warneri*, *flava*, *purpurata*; *Miltonia spectabilis*; *Mormodes citrinum*, *luxatum*; *Odontoglossum citrosimum*, *hastilabium*, *nævium*; *Oncidium divaricatum*, *longipes*, *luridum guttatum*, *pulchellum*, *pulvinatum*; *Peristeria elata*, *cerina*; *Phajus albus*; *Promenæa Rollisonii*, *stapelioides*; *Saccolabium Blumei*, *fureatum*, *guttatum*, *guttatum giganteum*; *Sobralia liliastrum*, *macrantha*, *macrantha splendens*; *Stanhopea area*, *Devoniensis*, *oculata*, *tigrina*, *tigrina lutescens*; *Vanda Batemanni*, *cristata*, *Roxburghii*, *teres*; *Warrea tricolor*.

Forcing Pit.

PINERY.—As pines colour, they should be kept moderately dry. Plants shy of fruiting should be kept dry for a while, to cause a check, and then be liberally soaked, and kept warm and moist, and the new growth will result in the production of fruit. But to check them before they are well matured may cause premature fruiting, and should not be done until the plants have had a long course of liberal culture. Young stock must be encouraged to grow strong, by allowing plenty of room in which to expand their leaves; give plenty of water, and repot as necessary.

VINERY.—In vineries great attention must be paid to keeping the foliage healthy to the last, as on this depends the maturation of the buds that are to fruit next season. Keep up a moist atmosphere, and watch vigilantly against red spider. Vines heavily laden with fruit must have the assistance of strong manure-water. Be careful not to cut away laterals too freely, as they are most useful in helping the maturation of the bunches. Be careful to keep the bunches shaded with a few leaves, by tying the laterals over where necessary.

Literature.

Our Own Fireside. Edited by the Rev. C. BULLOCK. Hunt and Co.—This admirably conducted monthly is ever fresh, interesting, and varied in its contents. The series of papers on life in the Arctic regions are rich in romance for the young, and most graphically depict the privations and trials to which Arctic voyagers are exposed. In the July number is an admirable paper on the life and works of Dr. Donne, just such a paper as we should regard as a model for a work of this kind. The Rev. F. O. Morris continues his fascinating stories of animal intelligence and resources. Mrs. Ellis's "Songs of the Garden" are weak, and appear to be without a purpose; and Mr. Round's compilations are heavy and spiritless. But such papers as that by the Rev. S. W. Christopher on Dr. Donne, or that on the Mouse, by C. A. H. B., atone amply for a few shortcomings; and no one now expects a magazine to be made of strong meat throughout.

British Grasses: an Introduction to the Study of the Gramineæ of Great Britain and Ireland. By MARGARET PLUES. Reeve and Co.—This compilation may be useful to many who do not care to enter into the subject thoroughly; but to the earnest naturalist it is of no use at all, and indeed is only addressed to beginners. Like the majority of beginners' books, it is not quite accurate in every particular, and the references and allusions betray very hasty and superficial study of the subject by the author. We read all that is written here about *Dactylis glomerata* without learning

that one form of it is in the foremost rank of ornamental plants employed in the embellishment of the parterre. The notice of *Holcus saccharatus* is far below what is required in a book published since the Hulletian revelations. The note on the botanical name of the Pampas grass is quite unworthy of a book professing to be scientific. At page 109 we are informed that there is a viviparous variety of *Aira caspitosa* "the seeds of which germinate without falling from the panicle." This is a wonderful revelation, and the strangest part of the story is that "the stem is comparatively short, but what it loses in height it adds in bulk." To be ungallant is very objectionable, but perhaps it would be still more objectionable to let this pass without challenging its truth, and asking if the author has ever seen the viviparous variety of this grass. One of the handsomest of all grasses, and the one which has always been so much admired as a pot-plant in the experimental garden at Stoke Newington, *Elymus glaucescens*, is dismissed with six lines in the chapter on ornamental grasses, and all we learn about it is that it "flourished well in Kew Gardens this year." *Arundo mauritanica* is said to require heat, which we were not aware of. Mr. Salter manages to grow the variegated form of it in the open ground at Hammersmith. As there are several references to the "Cottage Gardener's Magazine," we think it proper to say that there is not, and never has been a periodical bearing such a title. We forbear to grumble any more. There is of course much useful information in the book, and the pictures are very nicely executed.

A Handy Book of Meteorology. By ALEXANDER BUCHAN. William Blackwood and Sons.—Many handy books of meteorology have been published of late under various titles, and this is unquestionably the best of them all. The author presents a rare exception to the generally fanatical and visionary tone of writers on the subject, it being Mr. Buchan's especial gift to state clearly what he understands thoroughly, and without any admixture of superstition or speculation. This is a book for the meteorological worker as well as for the general reader, and we can without hesitation say that it will suit the majority of farmers and gardeners better than any other work they can purchase, for it is practical, business-like, and in great part taken up with considerations of the English climate and seasons. On the subject of weather forecasts, the author says, "No prediction of the weather can be made, at least in the British Islands, for more than three, or perhaps only two days beforehand, and any attempt at longer prediction is illusory. The principles laid down in the chapter on storms show the possibility and mode of making real predictions. Thus, if from telegrams of the weather it appears that barometers are everywhere high over Europe, then no storm need be dreaded for two days at least. That if on the following morning barometers begin to fall in the west of Ireland, and easterly winds blow over great Britain and Norway, and south-easterly winds over France, it is likely that a storm more or less severe is approaching the British islands. The indications ought now to be closely watched by the telegraph; and if the winds veer towards the south and west, and increase in power, and barometers in Ireland fall rapidly, a great storm is portended, the approach of which should be telegraphed at once to the seaports threatened by it. But if, on the contrary, barometers fall slightly, or cease to fall, and the winds do not increase in strength, the storm has either passed considerably to the north of the British islands, or its approach is delayed, and no immediate warning is necessary."

Old Jonathan; or, The District and Parish Helper, continues as attractive and varied as ever—one of the best of broadsheets for free distribution in villages, and amongst the poor anywhere. The issue for July 1st is almost wholly occupied with anecdotes and stories of animals, the principal object of the editor being to inculcate amongst those who have the care of horses, cattle, dogs, &c., the necessity and importance of kindly treatment. Some of the stories are amongst the best of the kind we have hitherto met, and we would instance particularly that of the intelligent pony belonging to Mr. Field, of Pimlico.

The Ladies' Treasury, edited by Mrs. Warren, continues to be entertaining and useful, and is so elegantly produced as to be a marvel of cheapness. There are plenty of good things in the recent issues for promoting industry and amusement in the schoolroom and the nursery, and thrifty housewives will surely be well repaid by consulting the pages devoted to domestic affairs.

RECEIVED.—*The Gospel Magazine and Protestant Beacon*, edited by the Rev. D. A. Doudney, D.D.; *The Watchmen of Ephraim*, edited by John Wilson; *L'Illustration Horticole*, Vetschaffelt, Ghent; *The Journal of Botany*, edited by Dr. Secman.

Correspondence.

NEW PLANTS FROM EQUATORIAL AFRICA.—As a constant subscriber to your valuable paper (the GARDENER'S MAGAZINE), I trust you will grant me space for my notice to your numerous readers. In the month of May, 1866, while on business in a colliery district in the county of Durham, I had the good fortune to make the acquaintance of a carpenter lately in the employ of Dr. Livingstone, the great African explorer, he having been sent home in consequence of losing his speech. I was lucky enough to obtain from him several very curious seeds, which, I was informed, the natives were in the habit of eating when on long journeys. After trying several plans, I have at last succeeded in cultivating them to perfection, which has caused me quite a business. I have already had several hundreds of visitors to see my wonderful plants, or, I should say, shrubs. As I dare not venture on your space to describe my mode of cultivation, I will in this instance only describe the plants themselves. In the first place, I can fearlessly say they are unquestionably new to this country. Those I have at present, which are seeding, have attained from six feet to six feet four inches in height, and a circumference of fourteen inches at the thickest part. The stalk is of a pure crimson colour, with here and there large fleshy protuberances of a yellowish cast, from which shoot the leaves, from five to seven in number, of a dark green colour, white nearer the edges at the top of the leaf for about a third the diameter, similar in appearance to variegated holly. The leaves are serrated at the edge, the flowers, of which there was an abundance, eclipse all in grandeur I ever yet beheld, being about twice the size of the tulip, the ground colour of the petals azure blue spotted with crimson, and streaked here and there with large yellowish streaks, feeling to the touch like velvet, the seeds of which I shall have some ready soon if dry weather prevails. I am informed by the giver they were used by them as pickles, and resemble in flavour gherkins. I shall be happy to let any of your numerous readers have a small quantity of seeds as soon as ready, the number to be

according to applications, providing they will pay for the trouble I may have in writing directions as to cultivation, finding stamps, paper, &c.; perhaps to make a small charge of one shilling or so to defray expence. I cannot supply any one with a large quantity. Hoping to be able to supply every applicant, in return for kindness received through your valuable paper, I subscribe myself, respectfully yours, &c.,

J. HESLTON.

3, St. Hilda Street, Hartlepool.

[We should like to see a plant, for it is not at all certain that this is new to science, though our correspondent may feel quite sure about it.—Ed.]

THE RED-BERRIED ELDER.—In the autumn of 1865 some discussion took place in the GARDENER'S MAGAZINE respecting the *Sambucus racemosa*, the scarlet elder, but which would be more correctly termed the coral-berryed elder, one of your correspondents—who was myself, under initials—observing, that no one who had not seen this shrub, as it is met with in many parts of Switzerland and Germany, can form any idea of its extreme beauty; and as it is perfectly hardy, it seemed extremely desirable that it should be introduced into and extensively planted in England; the only drawback—and it is a great disadvantage—being, that from its flowering very early, usually the latter end of March, the berries, which are freely formed, too generally wither or fall off; though I observed that on a young shrub which I then had a few berries had remained and ripened, and therefore gave hope that, in favourable seasons, on large shrubs some might generally do so. Another of your correspondents stated that he knew and highly valued the plant, which had been growing in his garden in Wales for several years, but from which the berries had uniformly fallen or perished, and therefore he deemed it useless to attempt its cultivation in this climate, though he thought it probable it might succeed better in Scotland, where it would probably flower later. Could it be acclimatised here, or got to flower, as our common elder does, in May, then in all probability it would retain its berries, as that does. In my garden here I have two shrubs—one purchased in England after my return from Switzerland in 1865, the other a seedling which sprang up unexpectedly in the following spring from the roots of a fern brought from thence. Both are now good-sized shrubs, and flowered freely this spring, and formed berries; but from the former they all withered up and fell off. Over the latter shrub I had some protection placed, and the result has been its retention of several of its berries, which have already assumed their bright coral colour. This shrub, in its present state, by no means conveys any adequate notion of its extreme beauty as seen abroad, but a fair notion can be obtained of its nature and character.

F. W. T.

PROLIFEROUS ROSES.—In the GARDENER'S MAGAZINE of this date is a reply to a correspondent, asking information as to the cause of the malformation of rose-buds, similar, I presume, to the one I enclose, which is one of many buds all alike, in several rose bushes scattered here and there in a gentleman's garden and grounds in this neighbourhood. On reading your reply, I thought it likely to be correct, until I noticed a bush with similar buds, one of fifty or sixty forming a bed in my own garden. Now this bed is full five, if not twice five years old. None of the other bushes in the bed are so affected; and I noticed that my neighbour's bushes and my own were all of the same kind of rose. In my own case, I do not think it can arise from over-manuring, or too fresh dung being applied.

J. R., Greenock.

[The sample sent in this case is of the kind which is most common. Those referred to last week were uncommon. That over-manuring will produce these monstrous growths we know, as the result of observation and experience; but we are well aware that such monstrosities occur where the soil may be suspected of poverty rather than excess of nourishment. The flower sent by J. R. is not expanded, but it appears to be a dark Gallica.—Ed.]

WHAT IS A VARIEGATED GERANIUM?—Would you kindly inform me, through the GARDENER'S MAGAZINE (for the information of the committee of the Peterborough Horticultural Society), if you consider *bicolor geraniums* to be, strictly speaking, *variegated*? and would a person competing for a prize offered for variegated geraniums, by exhibiting such varieties as Luna and Mrs. Longfield with tricolors, render himself liable to be disqualified? If you could let an answer appear in the next number, published on Saturday, the 6th instant, you would much oblige

Westgate, Peterborough.

JAMES W. EWART.

[Our opinion on this subject may be stated in a few words. The term "variegated" originally implied the presence in the leaf of a white or creamy margin, or a white or creamy disk, or otherwise a defect of colour. We strongly object to expand the meaning of such a term as "variegated," because custom should rule where there is no law. If, therefore, a schedule invites competition under the term variegated, Luna and Mrs. Longfield are disqualified. We could justify this opinion with a series of sound arguments, but have no time for it now. We will add, however, that if the term variegated is not restricted in meaning as we propose, it must quickly cease to have a meaning; for if you admit Luna because of its sulphur margin and cinnamon zone, you must admit Cerise Unique on account of its beautifully marbled leaf, and Commander for its radiate bars of two or three nearly distinct colours. It may be that schedules are indistinct on this point, but we must not for that reason play fast and loose with the technology of horticulture.—S. H.]

MR. MECHE'S MODE OF KEEPING POULTRY.—Do Poultry Pay?—That is a very proper question to ask, for I hold as a principle that everything that does not pay, directly or indirectly, should be abandoned as commercially and agriculturally wrong. I test this by the following propositions and comparisons:—It pays indirectly to produce cattle, sheep, and pigs; if so, why not poultry? It does not cost more to produce a pound of poultry, live weight, than a pound of meat, live weight. Well, then, do poultry sell at more or less per pound live weight than meat? The answer to this is, "A pound of poultry, live weight, always sells for much more than a pound of meat, live weight," and so the question is settled in favour of poultry. The average price of first quality beef is 5s. per stone or 7½d. per lb. for the whole carcass, net dead weight. The live weight price would therefore be 4½d. per lb., because, according to the best authorities, fat beasts lose 40 per cent. of their live weight in offal. The average live weight price of the best poultry is quite 9l. per lb., or double the price of beef, and not quite double the price of mutton. At this time of year poultry sells wholesale for much more than double the price of meat. Those I have sent to market recently have sold for 11½d. to 1s. per lb., live weight, against 4½d. live weight for beef, which is its present price. That settles the question so far, and the verdict is strongly in favour of poultry.

Poultry are evidently dear food to the consumer; but does it cost more food to produce a pound of poultry than a pound of meat, live weight? I answer, decidedly not; but the reverse. For my cattle and sheep don't eat worms and insects, whereas fowls consume them abundantly, and economize and apply every scattered seed or kernel that would otherwise be wasted. In another point of view, is the cost of attendance and shelter greater with poultry than with cattle? I reply, not. As to the production of eggs, that depends upon the quality and quantity of food administered, and the accompaniments of proper warmth and shelter. There is no fear of overstocking the market with either eggs or poultry; we consume daily one million of foreign eggs! I generally keep from 300 to 400 fowls. They have free access to every field during the whole year, and although they help themselves at harvest time when the corn is in sheaf, I always get my best crops of corn on fields adjoining the hen-house. I have this year two fields of wheat drilled, and only one bushel of seed per acre. They come within 10 to 20 yards of the fowl-house, and are a perfect plant, although the poultry have been scratching and cultivating the fields ever since they were drilled. We are apt to forget that fowls, like sheep, manure where they go. I must say I used at one time to feel nervous and angry when I saw them hard at work on the newly-sown corn, but I soon learned to feel confident that insects were their principal gain, and that my well and deeply-deposited corn escaped.

J. J. MECHE.

Replies to Queries.

P. F. L. S.—It is only in rare and exceptional cases we attempt to name plants from leaves. There are thousands of plants with such leaves as you send.

P. S. D. S.—1, *Selaginella brasiliensis*; 2, *S. formosa*; 3, *S. serpens*; 4, *S. denticulata*; 5, *A. Lomaria*, which cannot be determined without the fruit; 6, *Pteris cretica albo-lineata*.

Potatoes for Garden and Field Culture.—J. D. R., dating from Cobourgh C. W. America, asks for the names of two best early, two best second early, and two best field potatoes. He says (writing on May 29th), "Our spring is very backward; if it continues dry for about two or three days, I shall be able to plant potatoes, and vegetation is so rapid when the weather gets warm, that we shall be able to dig potatoes on or before the 15th of July." To name the two best for our correspondent is impossible; we might be many years engaged in tilling his ground ere we could say which were the two best of any class; but he cannot go far wrong in taking, for first earlies, Smith's Early, or Curly (it has two names), and Myatt's Ashleaf. For second early, King of Potatoes and Wheeler's Milk White. For field culture, Paterson's Victoria and the old Red Regent. The Skerry Blue is a capital field potato, and we have one called American Red, received this season from Messrs. Gibbs and Co., of Down Street, Piccadilly, which we believe will prove the finest variety hitherto seen for field culture and market. In size, flavour, and hardness A 1, but we have yet to learn if productive.

Corrosive Sublimate to destroy Earthworms.—Amicus.—The following is a recipe originally published in the "Garden Oracle for 1864": Corrosive sublimate 1 oz., common salt 1 tablespoonful, boiling water 1 pint; stir till dissolved. Pour the mixture into 9 gallons of rain-water, and water the lawn or the soil in flower-pots, wherever, indeed, the worms that annoy are to be found. We must confess we do not understand how any real difficulty about getting rid of earthworms can arise in any garden. Lime-water can be made with the least possible amount of trouble, and is always effectual.

Roses in Greenhouse.—Ib initio.—If your roses make long shoots in the house, it is a proof the house is not well adapted for them, or that they are kept too far from the glass. The sort of house that suits roses is one with a nearly flat low roof, and the treatment should comprise ample ventilation; and heat must be applied with the utmost caution, as any excess is a most serious injury. As you ask about mildew, we advise that you secure a good growth by means of a generous compost and sufficient water, for when roses grow freely they are but seldom affected by mildew. But for the immediate treatment of mildew there is nothing so effectual as dusting with flowers of sulphur. The plants you suppose to be eaten by earthworms are probably eaten by slugs; earthworms do not eat growing plants, and upon the whole are very beneficial, and should therefore not be recklessly destroyed. Of course they are a nuisance in flower-pots, but in the common soil and on grass lawns directly beneficial.

J. Stimson.—Your communication respecting distribution of tulips on the 1st of July came into our hands on the 2nd.

Ants.—S. W. B.—We have published a great many recipes for dealing with ants, and we really cannot offer you anything new. A few weeks ago we observed in a bed of flowers one particular plant in the process of being smothered in the way that ants do smother plants effectually and quickly. We placed close beside it an empty flower pot inverted, and with the hole stopped with a piece of rag. The ants discontinued their work of entombing the plant, and took to the empty pot, which now contains the nest. At any moment we can remove it, and consign the nest to destruction; but probably we shall leave them to enjoy their home undisturbed.

Thrip on Melons.—D. M.P.—The only safe course is to fumigate with good tobacco, and apply the syringe freely afterwards. Thrip and red spider are common pests of melons in consequence of a frequent mistake of cultivators. It is known that melons require less moisture and more sun than cucumbers, and some cultivators go to an extreme and allow their melons to be roasted, not knowing how to hit the happy medium.

Golden Balm.—Veritas.—This beautiful plant is at its best during April and May. In the course of June it becomes dull in colour and too strong in growth, and is sometimes eaten up by red spider. A pretty sure way of making a second display is to cut it down close about the 15th of June, and give it a heavy soaking of water a week afterwards.

SUBSCRIBERS TO THE GARDENER'S MAGAZINE who desire to extend its sphere of usefulness, and are willing to interest themselves in promoting its still wider circulation, can materially further this object by sending to the publisher the names and addresses of persons they think are likely to become subscribers, who will forward to each a specimen copy free. A stamp must accompany each name and address sent, to cover the postage of the specimen copy.

The Gardener's Magazine.

SATURDAY, JULY 13, 1867.

GOOD ENGLISH RAISED ROSES are so few in number that we ought to offer something like an ovation to MISS INGRAM, the charming beauty that made her *début* at the second great exhibition of the Royal Botanic Society, 1867. As we saw it on that occasion, it reminded us of Madame Alfred de Rougemont, but as we have since seen it at the Crystal Palace, and Birmingham Town Hall, and lastly at Stoke Newington, we would prefer to compare it to Madame Vidot, Madame Hoste, Mrs. Rivers, and to say, as the end of the comparison, that it is extremely likely to surpass all these roses in free growth, amplitude and beauty of foliage, and the perfect finish of its globular, thick-petalled, delicately-tinted, and odoriferous flowers. Although prepossessed in its favour in the first instance, when making notes on flowers that had travelled far during an arid and heated condition of the atmosphere, we were delightfully surprised when it came into our hands a few days since, under circumstances which afforded opportunities for leisurely inspection. One of the peculiarities of this beautiful variety is in its leafage. The leaflets are longer and more glossy than is usually the case in hybrid perpetuals; there is in the hard surface and the purplish leaf-stalks what cultivators would call a taint of China blood, and one might almost believe that the fresh and delicate odour of this rose had in it a dash of the true Tea fragrance. As a hybrid perpetual it may be regarded as in some respects peculiar, and as a rose for the garden and the exhibition table it may be regarded as in all respects desirable, valuable, and a triumph for Mr. Ingram, of Frogmore, the fortunate raiser, and an encouragement to English rosarians everywhere to apply themselves to the entertaining and exciting pastime of growing roses from seed. Miss Ingram will be one of the most renowned of the little family of English raised roses, a family of quite recent creation, but which increases fast, and with every increase confers a new honour on the land of its nativity. John Hopper, Princess Mary of Cambridge, Beauty of Waltham, Lord Herbert, Lord Macaulay, Lord Clyde, King's Acre, Queen Victoria, and Princess of Wales, are conspicuous members of the English family of named roses. We believe Miss Ingram will prove to be the most beautiful, most worthy, and the most generally favoured of the group, and most gladly apprise our rose-loving friends that in due time Mr. Turner of Slough will be happy to afford them the means of judging for themselves of the merits of the new variety, by that best of all tests, its cultivation in their own gardens.

DEATH OF MR. GEORGE PAUL, OF CHESHUNT.—It is our painful duty to have to announce the death of Mr. George Paul, the much respected head of the celebrated firm of Paul and Son, of the Old Nurseries, Cheshunt. Mr. Paul has been more or less afflicted during several months past, but lately he rallied, and resumed his wonted activity; and his demise on Saturday last was a sudden and unlooked-for event, although he had but so recently recovered from a long and severe illness. It is but proper we should associate with this sad announcement a word in testimony of the deserved esteem in which Mr. Paul was held by all who knew him. In the love of truth, in upright dealing, in business enterprise, and in practical skill and extent of useful knowledge, the deceased gentleman stood far apart from the average of mankind; and to enjoy an hour of his society at any time was to be assured that goodness and gentleness were not yet extinct. Wherever his name was mentioned in the horticultural world it was accompanied with expressions of respect; and we feel assured his loss will everywhere be felt as making a great gap in the circle of able and upright men who take the lead in the horticultural enterprises of this country. Mr. George Paul, hitherto the junior partner in the firm, but now its head, is too well known to need any introduction to public notice in this place. But we cannot refrain, while recording the death of the father, from testifying that the son is well fitted to walk in the footsteps of one who was loved at home and honoured abroad; and we can have no better wish for our friend than to wish him abundant prosperity, and a like share of the world's esteem to that enjoyed by his her.

No. 115, NEW SERIES.—VOL. X.

MR. MEECH'S FARM AT TIPTREE will be open to public inspection during the period of the Agricultural Society's exhibition at Bury. No introduction or cards of admission will be necessary.

A SHOWER OF PEBBLES.—A Belgian paper, the *Gazette de Mons*, relates that in the afternoon of June 24th, during a storm which broke over Frameries, a shower of small pebbles fell from the sky. Several of them were collected, and found to be about the size of a small nut. The composition is a sort of enamelled silex, resembling Jasper.

THE CRITICISM ON THE JUDGING OF THE AZALEAS shown by Mr. Turner and Messrs. Glendinning at Regent's Park, which appeared in last week's issue, contained a trifling error, which may as well be rectified. The competition and the judgment to which our remarks referred occurred at the first great exhibition, May 29th, and not to the second show of June 19th, as stated. The error does not affect the argument at all. It is but a slip of the pen, but we are nevertheless greatly obliged to a correspondent who has called our attention to it.

THE STEALING OF PLANTS FROM PUBLIC GARDENS in the metropolis is becoming so general that the managers of those places are compelled to adopt special means for the repression of the practice. A short time since one Thomas Linfield, a groom, was charged at Marlborough Street Police Office with stealing geraniums in Hyde Park, and Mr. Knox, the presiding magistrate, inflicted a fine of 40s. or one month's imprisonment. At Worship Street Office, Charles Lyles, a well dressed lad, was charged before Mr. Newton with having pulled up some geraniums in Victoria Park, and was fined 10s. or a week's imprisonment. Perhaps it may tend to lessen the number of such offences to make it known that in the present state of the law places of general resort are fully protected; they have been so, indeed, since a mischievous youth made himself hatefully notorious by smashing the Portland Vase. The flowers, trees, &c., in the London parks are considered by the law as the property of the Commissioner of Works, and he therefore has power to prosecute for theft or damage.

ROYAL BOTANIC SOCIETY.

THIRD GREAT SHOW, WEDNESDAY, JULY 8.

This, the last show of the season at the gardens of the Royal Botanic Society, was as interesting as any that preceded it, though many degrees less attractive, owing to the absence of azaleas, pot roses, and other subjects that contribute in a special manner to the enrichment of the earlier exhibitions. Ferns, palms, and cycads were abundant, and afforded a grand wealth of greenness and variety of form, and in respect of colour there was a glorious bank of pelargoniums, some fine collections of zonal varieties, a good bank of orchids, a fair sprinkling of heaths, plenty of cut roses, carnations, and pansies; and amongst the stove and greenhouse plants, Allamandas, Ixoras, Clerodendrons, Pleromas, and other showy subjects. The pelargoniums were arranged, as usual, on the long bank at the upper end of the tent, the orchids on a cross bank under the shadow of a bank of ericas; lower down, right and left, were banks of zonal pelargoniums; beyond these a pretty group of novelties from Messrs. Veitch; on the boundary banks every way the usual display of stove and greenhouse plants, wherein fine-foliage subjects were conspicuous for their abundance and beauty; and beyond all, the corridor, with a plentiful display of fruit and cut flowers. It would greatly improve such an arrangement if the orchids were favoured with a rear wall of green baize or a row of coniferous trees in pots, for when we walk between them and the bank immediately adjoining, the orchids show to a great disadvantage; in fact, the back view of anything, from an orchid to an elephant, is unfavourable to an agreeable first impression. The show and fancy pelargoniums were pretty much the same kinds as we have already reported on this season, and the principal exhibitors were Messrs. Fraser, Mr. Nye, Mr. Ward, and Mr. Wiggins. We made note of only two particulars in this department, namely, that Mr. Fraser's fancies were remarkably fresh and delightfully perfect in training and finish, and that Mr. Ward had, in a collection of good show varieties, one called the Rival, which appeared to be about as finely formed a flower as any in the whole of this fine display. In case this variety is not known to the generality of our readers, it may be as well to add that the lower petals are deep salmon colour overlaid with lake veins; the top petals maroon shading to black. From these we turn to the zonales, upon which we have made very few notes this season.

ZONALE PELARGONIUMS.—Mr. Ward, gardener to F. J. Wilkins, Esq., Leyton, and Mr. Catlin, gardener to Mrs. Lermite, Finchley, were equal first in the class for six with very fine plants. Mr. Ward had Madame Bouchardet, a fine salmon; Sobieski, intense scarlet; Louis Roeseler, in the way of Herald of Spring, but apparently lighter in colour, one of the finest plants in the tent; Rose Rendatler, superb in every respect, and the finest zonal of the day; Monsieur Rendatler, a splendid salmon-coloured variety; and the Clipper, a fine scarlet. Mr. Catlin had Smith's Excellent, Tintoret, Madame Vaucher, Monsieur Rendatler, Scarlet Globe, and Monsieur Martin. The last named showed too many sticks; all the rest were in perfect finish. As our country readers sometimes ask about the London style of growing these things, we took the trouble to measure Mr. Catlin's plant of Excellent. It measured four feet over, in a regular low convex outline, and had 66 trusses full open, not a withered flower visible, and every leaf in its place. Mr. Windsor, gardener to J. R. Ravenshill, Esq., Walthamstow, put up a grand six, the names of which we missed. Mr. Winter, gardener at the Elms, Golder's Green, Hendon, had a fine group in too flat a style of training; the varieties were Scarlet Globe, Gem of Roses, too shy for exhibition; Senator, Cerise Unique, a blaze of colour; Madame Vaucher, Charles de Mas, a green-leaved scarlet of good form and fine deep colour. Mr. Weston, gardener to D. Martineau, Esq., of Clapham, had nice small plants in an admirable condition.

SEEDLING ZONALES.—From Mr. Thorpe, Little Thorpe Gardens, Leicester, *Fairy Princess*, leaves darkly zoned, flowers white with pink centre, petals not broad enough; *Sparkler*, a zoned scarlet, of average good qualities; *Salmon King*, neat dark zone, flowers clear salmon, good form, nicely finished; *Starter*, a showy Cybister-like variety. From Mr. Pottle, gardener to B. D. Colvin, Esq., *Eastern Beauty*, a neat zone, flowers salmon, with wash of red; *Beauty Supreme*, a noscay variety, the flowers rosy pink. From Messrs. Downie, Laird, and Laing, *Countess of Rosslyn*, rose pink; *Seraph*, Mrs. Laing, deep crimson scarlet. These have been described and characterized as much above average merit. Mr. Hally, of Blackheath, sent two double-flowering varieties which did not appear to possess any particular merit. *Nimrod* is a brilliant scarlet. *Rose Queen* is a good scarlet colour. With these a single variety called *Hydrangea*, which appears to be a considerable degree inferior to Pink Beauty. A few tricolor-leaved varieties were to be found of course. Mr. C. Turner, of Slough, sent a beautiful variety named *Miss Turner*; the leaf is flat and round, margin yellow, zone chestnut and bright red; in every respect first-rate. Mr. Watson, of St. Alban's, sent *Enchantress*, a first-rate tricolor, in the style of Miss Watson. Mr. Bull contributed the entire collection of Mr. Will's varieties, which he is preparing to send out, and a magnificent lot they are. The following were noted in addition to those already described:—*Admiration*, probably the finest of all the bronze zonales in existence, the margin and disk rich sulphur, zone broad, the colour bright reddish brown. *Rosalind*, very neat habit, fine dark chestnut zone. *Compactum*, in the style of Luna, but with more colour. *Painted Lady*, disk and margin sulphur, broad zone of rich red brown with distinct shade of pure red, remarkably rich, and rather curious, too, in colouring. Mr. Thorpe, of Leicester, sent *Earl Howe*, a pretty tricolor, the leaf large, more or less rayed, zone broad with much rust-red and black colouring; good.

NEW SHOW AND FANCY PELARGONIUMS.—From Mr. Nye, *Archduke*, large and handsome, bottom petals carise red overlaid with lake veins, top petals maroon shaded to a rosy edge, clear white throat; fine. From Mr. Turner, *Woman in White* (Hoyle), lower petals pure white, top petals large deep rich crimson, with violet veins at the base; beautiful. From Mr. Kimberley, of Coventry, *Lizzie*, small, nice form and flat, lower petals pale lavender with rose veins, top petals lavender with rose veins and small black spot; novel, distinct, and pretty, yet not at all a desirable flower. *Grand Arab*, medium size, lower petals clear flesh with small bluish crimson spots, top petals blackish crimson with whitish edge; very showy and distinct, but not a well-finished flower.

ORCHIDS.—The Leicester lot shown by Mr. Brockhurst, gardener to A. Turner, Esq., took the lead in the class for fifteen, Mr. Penny taking second place, Mr. Wilson, gardener to W. Marshall, Esq., third, and Mr. Peed fourth. Mr. Brockhurst's plants were *Aerides affine*, *Odontoglossum Pescatorei*, *Saccolabium guttatum Holfordii*, *Cattleya Warneri*, *Saccolabium Blumei majus*, *Odontoglossum cordatum*, *Aerides Larpente*, *Phalenopsis amabilis*, *Lælia purpurata*, *Odontoglossum hastilabium*, *Cattleya Dowiana*, with two of its gorgeous purple, buff, and gold coloured flowers, suggesting what we may expect when this rare orchid attains exhibition size; *Vanda insignis*, *Cypripedium barbatum majus*, *Saccolabium guttatum*. Mr. Penny's plants were *Trichopilia crisa superba*, finely done; *Cypripedium barbatum superba*, *Cattleya Mossiae superba*, *Odontoglossum neivium majus*, a very fine example both in respect of the variety and the perfection of its cultivation; *Aerides odorata purpurascens*, *Aerides Lobbia*, *Cypripedium barbatum superbum*, *Odontoglossum cordatum*, *Vanda insignis*, *Saccolabium guttatum*, *Epidendrum vitellinum*, *Aerides crispum amethystina*, *Dendrobium filiforme*, with thirteen spikes of its curious and delicate flowers; *Aerides affine superba*, *Anguloa Ruckeri*. In Mr. Wilson's lot were *Phalenopsis Luddemanniana*, admirably done; the curious and rare *Cypripedium Stonei*, a good *Lælia purpurata*, *Oncidium pulvinatum*, *Oncidium leucochilum*, *Cattleya Mossiae*, *Dendrobium eburneum*, and others. The best group of eight came from Mr. Wiggins, gardener to W. Beck, Esq., Isleworth. This group consisted of *Cypripedium villosum*, *Cypripedium Hookeri*, *Odontoglossum hastilabium*, *Aerides virens major*, a very fine plant; *Aerides Schrederi*, with four spikes of flowers; *Epidendrum vitellinum*, *Cypripedium barbatum*, and *Aerides crispum*. From Mr. Hill, gardener to R. Hanbury, Esq., a good eight, in which were examples of *Cypripedium Stonei*, with two flowers; *Odontoglossum Schlieperianum*, with one spike consisting of eleven flowers, the colours green, yellow, and brown. Mr. Page, gardener to W. Leaf, Esq., Streatham, had a nice group comprising *Cypripedium Lowii*, with three flowers, and a good *Trichopilia crisa*. In the trade class, Mr. B. S. Williams took first place with *Cypripedium barbatum superbum*, *Lælia purpurata*, *Phalenopsis grandiflora*, *Anguloa Clowesii*, *Vanda suavis*, and *Aerides odoratum majus*.

CARNATIONS, PINKS, AND PICOTEES.—The names of the best stands of these will no doubt be welcomed by many of our readers as affording the best suggestions for the formation and improvement of collections. Mr. Turner, of Slough, put up the best collection of **CARNATIONS**, comprising *True Blue*, a new variety, of medium size, marked with heavy flakes of bright purplish rose, beautiful and novel. In the same stand Lord Clifton, Dr. Foster, Lorenzo, Fanny Gardener, Prince Albert, Merrimac, Duchess of Kent, Annihilator, Ruth Hannah, Flora's Garland, Young Milton, Earl Stamford, Justice Shallow, Lady of the Lake, John Keil, Brutus, John Rect, Cradley Pet. Mr. H. Hooper, of Widcome Hill, Bath, had *Venus*, *Beautiful*, *Stone's Venus*, *Mayor of Nottingham*, *Parker's Garland*, *Prince of Wales*, *Jefferson Davis*, *Gem*, *Duke of Cambridge*, *Grand Master*, *Oriana*, *Juno*, *Beauty of Woodhouse*, *Glory*, *Excellent*, *Diana*, *Neptune*, *Fanny Gardener*, *Standard*, *Victor*, *Florence Nightingale*.—Mr. Turner, of Slough, and Mr. Hooper, of Bath, exhibited **PICOTEES**. Mr. Turner showed Mrs. May, Miss Wood, Duke of Devonshire, Miss Sewell, Mrs. Dixon, Prince Arthur, Miss Williams, Eliza, Forester, Robin Hood, Eiris, Amazon. Mr. Turner took first place with twenty-four **PINKS**; the varieties were Rev. G. Jeans, Annette, Attraction, John Ball, Celestial, Titus, Marian, Device, Exhibitor, Charles Turner, Invincible, Bertram, President, Goliath, Alma, Delicata, Aurora, Purity, Blondin. Mr. Bragg, second, with Blondin, Purple Prince, Nonpareil, Mr. Bragg, Dr. Maclean, Hector, Device, John Ball, Ernest, Beauty, Attraction, Rifleman, Victory, Celestial, and ten seedlings. Besides these, Mr. Bragg presented *Nonpareil*, broad laced purplish rose, scarcely rich enough for its class. From Mr. Sbenton, Biggleswade, *Primrose Queen*, large primrose white showing much green at the base; bad. *Leviathan*, large, light rose lacing, blackish crimson at base of petals; this appears to be a good pink, but when we saw it it was falling to pieces, probably in consequence of the heat of the weather and the draughty place it was in. *Sultan*, small, very heavy lacing of maroon crimson; fine. *Ethel*, lightly edged rose, heavy

maroon crimson base. Mr. Pizzey, gardener to Mrs. E. Fulmer, of Slough, took the small silver medal for a beautiful dozen; they were Rev. G. Jeans, Blondin, John Ball, Attraction, Marion, Scarlet Gem, Device, President, Ernest, Bertram, Delicata, Cristabel.

PANSIES.—Messrs. Downie, Laird, and Laing, of Frederick Street, Edinburgh, and Stanstead Park, Forest Hill, took the first place in the class for thirty-six; the varieties were Kinleith, Attraction, Prince of Prussia, La Déb, Mary Lamb, J. B. Downie, Rev. H. Dombain, Invincible, Blink-bonny, Isa Craig, Ladyburn Beauty, Chancellor, Lavinia, Arab, Cherub, Princess of Wales, Lord Clyde, Jessie Laird, Francis Low, Countess of Rosslyn, Perfection, Miss Williamson, Novgorod, Czar, Peeress, Eclat, Cupid, C. W. R. Ramsay, Dux, Lady Lucy Dundas, George Wilson, Miss Hopkins, Gem, Village Maid, General Lee. Mr. Hooper, of Bath, second, with Attraction, Baroness, George Catley, a fine small dark self; Sunset, Lady E. Studley, Sir Launcelot, Ajax, Mr. T. Moore, Harry, New Colour, a self, curious rosy purple, with shade of puce, very beautiful; Randolph, Lord of the Manor, Mrs. Gladstone, Flower of Spring, Alexander the Great, Miss Williamson, Novelty, Snowball, Queen of Beauties, Princess Helena, a beautiful white ground flower; John Gray, Princess of Wales, Purple Perfection, Francis Low, Narcissus, Cream of the Creams, Countess of Rosslyn. Mr. Bragg put up a good thirty-six, and Mr. Adair, of Aliceville, Edinbrough, presented a pretty twenty-four, comprising Attraction, Miss Hill, Ladyburn Beauty, Invincible, Chancellor, Mrs. J. White, J. B. Downie, Arab, Princess of Wales, Cherub, Lavinia, Francis Low, Cupid, Miss Ramsay, George Wilson, Lady L. Dundas, Perfection, Eclat, Alice Downie, General Lee, Countess of Rosslyn, Miss Muir, Czar, Jessie Laird. From Mr. Hooper, of Bath, a new bedding pansy, called *Sunset*, medium size, bright gold yellow, with small dark central spot. **FANCY PANSIES** were contributed by Messrs. Downie, Laird, and Laing, the varieties being Maccaroni, Oriana, Black Prince, Mrs. R. Dean, Mrs. H. Northcote, Wm. Moffatt, Ninian Neven, Amy, Eola, Prince Napoleon, Magnificent, Indigo, H. W. Adair, Mrs. T. Scott, Striped Queen, Punch, Harlequin, Princess Alice, Figaro, Noemi Demay, Colleen Bawn, Jeanette, Pacha, Prince of Wales, Princess Matilda, Caffra, Earl of Rosslyn, Mrs. Montgomery, John McNab, Belle Lelloise, Emblem.

VERENAS.—Mr. Perry put up a splendid group of twenty-four varieties, the following amongst them being new varieties: *Emma Perry*, large pip, fine stout petal, colour pale flesh, with rich carmine eye. *James Birbeck*, very large, brilliant carmine with crimson shades. *J. C. Ward*, clear light purple, with gray eye; quite distinct from William Dean, and a very desirable colour. *Striking*, large, deep crimson, with red shade and clear lemon yellow eye. *Splendid*, a quite new colour, being as nearly as possible that of Lord Elgin cineraria, say clear vivid magenta. *Miss Turner*, white, with delicate rose eye. *Miss Mole*, purplish rose changing to slaty rose. *Interesting*, carmine scarlet changing to carmine red; large lemon coloured eye. These are all large finely formed flowers, and represent the highest type of exhibition verbenas. Mr. Perry having raised his strain of seedlings to a degree of perfection which we believe has no equal in this country. With these the following of previous years, from the same seed-bed: *Leab*, puoy rose pink, lemon eye. *William Dean*, deep indigo purple, primrose eye; one of the most splendid verbenas in cultivation. *Indispensable*, bright crimson purple; *Mazeppa*, intense scarlet, pale lemon eye; *Champion*, deep velvety crimson, with blackish shade, and small gray eye; *Delicata*, brilliant bluish pink, grayish eye; *Meteor*, deep reddish crimson, gray eye.

NOVELTIES AND MISCELLANIES.—The beautiful bank of plants from Messrs. Veitch and Son, in which were many valuable plants of recent introduction. Here we found the glorious *Cattleya Dowiana*, the splendid colouring of which fully justifies M. A. Verschaffel's showy picture of it; the plant had two flowers richly coloured buff and purple; it needs only time to take rank with the most popular of exhibition orchids, *Dendrobium Bensoni* is now well known to cultivators, and is certain to become a favourite. *Croton interruptum* is interesting and curious; the leaves are long and linear, the young leaves are rich green, with central gold yellow stripe, the old leaves bronzy green with dull red stripe. *Croton irregulare* has leaves an inch wide and a foot long, rounded at the base, some of them slightly twisted; all of them dark green, with gold yellow stripe. *Neirembergia rivularis* is a charming species, with tufts of neat grass green leaves, and pretty white salver-shaped flowers; quite a gem in this class of plants. *Begonia Veitchii* is one of the most distinct begonias known, the leaves small, dull green, in tufts from amidst which rise few-flowered scapes, bearing large flowers of an intense orange red colour. *Abutilon Thomsoni* has elegant sagittate deeply lobed leaves, the colours of which are grass green and rich gold yellow in about equal proportions; a charming plant for those who love elegance in variegated leaves. *Acalypha tricolor* is a plant of distinct and noble character, with large floccid leaves of a deep solemn bronze colour, occasionally overlaid with oblique bars of orange scarlet; a quite new style of leaf-colouring. *Blandfordia Cunninghamii*, a charming greenhouse plant, with tubular flowers of bright orange. *Leptopteris superba*, the richest habited of all known ferns. *Adiantum concinnum latum*, a bold form of a well-known fern. A pretty variety of *Irish Yew*, with golden-tipped shoots. A series of new *Gloxinias*, the best of which were *Prinse of Teck*, upright flowers, delicate carmine, whitish tube. *Madame de Smet*, soft lavender, white tube. *Vlaanderen*, richest carmine. *Topaz*, erect flowers, curious shade of red with shades of carmine; the tube slightly tinged yellow or buff. All first-rate except the last, which is showy, but scarcely equal to the demands of the present day. Mr. T. Thorpe, of Leicester, sent a new verbenas, named *Rev. E. N. Pochin*, the colour rosy purple; not good. Mr. George presented examples of his useful series of *Compactum Tropæolums*, but not in a very good condition. A new one of this series is *Le Grand*, a large bush-like plant, with large finely formed scarlet flowers. Mr. Thorpe presented a beautiful single *Petunia*, called *Single Beauty*; the form is all that can be desired; rich rosy purple centre, and rosy purple veins on a bluish ground; this is a valuable novelty. Mr. Bull presented *Petunia Official*, single, small, neat, rich rosy purple, with clear white stripe in the centre of each petal. *Madame Pisançon*, very large double; the form fine, colours white or bluish, with light lavender veins. *Interesting*, a single flower, beautiful in form, and distinct and novel in colouring, being equally divided with bars of bright purple and pure white. Mr. G. Smith, of Hornsey Road, sent a small plant of a new double-flowered *Fuchsia* of most charming character. The name is *White Unique*; the flower is rather small, corolla almost globular; most neatly and delicately put together; sepals broad, and set horizontally like wings, colour bright coral red. This is certain to become as great a favourite as any of Mr. Smith's valuable contributions to florists' flowers. Mr. Blston, gar-

dener to S. Lawrence, Esq., Clapham Park, sent *Panacratium fragrans*, a beautiful plant that has been more or less known to cultivation for half a century, but nevertheless well merits special mention, and much better appreciation than it has hitherto obtained. Roses were past their best, but a new variety was shown by Mr. Mitchell, of Piltown, which no true critic could pass by. The name is *Madame Hoste*. It is most beautifully formed, and comes nearest to *Madame Vidot* in character, but is larger, and, by the wood and buds that accompanied the flowers, appears to be a good grower, and very free to flower, qualities of which the charming *Madame Vidot* is deficient.

Fruit.—There was nothing new in this department, but some of the exhibits were exceedingly good. A grand collection came from Mr. Miller, gardener to the Earl of Craven, Combe Abbey, near Coventry. Mr. Rawbone, gardener to C. M. Campbell, Esq., Derby, another good collection. From Mr. Johnson, gardener to the Marquis of Aylesbury, a third good collection. Several other good collections besides these, all comprising good subjects well done. Pines good and in sufficient quantity. Grapes fine and abundant. In Mr. Miller's collection, Black Hamburgs huge in bunch and berry. Messrs. Lane and Son, of Berkhamstead, showed three bunches of Buckland Sweetwater weighing 9 lbs., one bunch of the three weighing 4 lbs. 8 oz. Mr. Standish showed Royal Asot Grape, a fine black grape with flesh and flavour not greatly differing from Black Hamburg, very handsome in bunch and berry. We must pass over other subjects, but reserve space to say that, in looking for subjects of special merit, we could not help noticing a dish of Dr. Hogg strawberry from Mr. Turner; the berries sumptuous in size and colour, far surpassing the finest Queens, and with the true Queen flavour. When visiting Mr. Turner in the Auricula season, we tasted samples of this strawberry forced, and thought the flavour scarcely inferior to out-door fruit. Lastly, Mr. Bennett, of Osberton Hall, Worksop, Notts, presented a dish of Vanilla planifolia, perfectly ripened and deliciously odorous. For this he received deservedly the small silver medal. Thus ends the season at the Royal Botanic Gardens, scarcely favoured by the weather, but admirably supported by practical cultivators and the horticultural public generally; a season by no means destitute of brilliant features, and upon the whole successful, as good management, and good feeling, and a liberal spirit deserve. May the Society never have a worse season than that of 1867. S. H.

THE BIRMINGHAM ROSE SHOW.

THURSDAY AND FRIDAY, JULY 4TH AND 5TH.

The Sixth Rose Show in the Town Hall, Birmingham, was not quite equal to some of its predecessors, yet it surpassed in both the quality and abundance of the flowers all the exhibitions of roses that have been held in or near the metropolis this season, and we may most properly pronounce it the most interesting and important exhibition of its kind of 1867. The Town Hall of Birmingham is admirably adapted for the purpose, being spacious, airy, well lighted, and in a central situation. The hall, the promoters of the show, the exhibitors, and the flowers, were all praiseworthy; yet the inhabitants of Birmingham do not support this exhibition as it deserves to be supported; the committee have no surplus to carry to a reserve fund, and financially this affair lives by the skin of its teeth, though in a floral sense it is one of the most successful undertakings of its kind in the country.

The getting up of this show was tasteful and effective, and we direct attention to a few particulars for the benefit of exhibitions generally. The vast space of the floor of the hall was divided into alleys or walks, by means of four long tables. On these the roses were placed in double rows, but the two tables next the central or principal space for promenading were additionally decorated with potted plants of the peculiarly striking variegated *Acer negundo*, the whitest of all white-leaved plants, and as graceful as it is peculiar, and potted plants of Maize alternating with the *Acers*. The whole of these had been grown under glass to enhance the delicacy of the colouring, and the result was a most delightful effect; the roses were enhanced in richness of appearance by the contrast, and the objectionable flatness of a great display of cut flowers was extinguished. Looking up from the centre of the hall, the orchestra at one end, and the gallery at the other were seen to be abundantly embellished with boxes of roses, vases, ornamental glass, and wire-work adapted to various horticultural purposes, one of these special features being a huge rose pavilion, with real roses trained to the arches, and showing abundance of fine flowers. The inspection of the numerous objects of beauty and interest in the galleries afforded a scarcely less agreeable entertainment than the view of the vast field of gorgeously coloured and powerfully odorous roses on the tables below. Yet with all this provided for their delectation, and with harp solos and a first-rate band, the people of Birmingham were languid in their attendance, and the committee will probably be scarcely able to make their incomings meet their outgoings, which of course are heavy, though, to the credit of the Corporation, it must be mentioned that the Town Hall is granted for the purpose free of all expense.

As to the roses, there was noticeable throughout an average goodness that gave general satisfaction to cultivators and connoisseurs of the Queen of Flowers. There were a few comparatively poor stands of course, but not one thoroughly bad; and as to good ones, they were the rule, and the leading collections were grand for quality, variety, richness, freshness, and skilful staging. That indescribable class of "practicals," who make a perpetual and wearisome fuss about the superiority of old over new varieties of garden plants, who will coolly insist that there are no roses, tulips, dahlias, or verbenas, now to equal those they were accustomed to grow and exhibit half a century or so ago, might, with some profit to their idiosyncrasy (into which word we might very properly introduce a τ), have gone round the show with a few old catalogues in their hands, with a view of finding old roses and establishing their superiority over new ones. We might almost say there were no roses shown but such as have been introduced within the past five years; certainly those of less than five years' place in our lists constituted the bulk of the exhibition, the simple reason being that, as a rule, old roses cannot be shown against new ones, the quality of named varieties having been so immensely improved of late years. Our lists of the winning varieties will show that whoever desires to have the best roses, must take the bulk of his selection from the newest kinds. New roses are not necessarily good, and the French send us annually a rather large proportion of second-rate varieties, but with them come beauties unsurpassable among existent catalogued varieties, destined, we may believe, to be surpassed in their turn, but for the present, and for some years to

come, certain to be regarded as types of the nearest approach yet made to the standard of perfection. Such old roses as *Madame Vidot*, *Mrs. Rivers*, *Jules Margottin*, *Gloire de Dijon*, *Devoniensis*, and *Lamarque* keep their place by right of intrinsic merit, and their once companions in the exhibition boxes would be with them now except for the little accident that they are beaten; and those that we name, and others that we might name as old, yet valued, must yield to better when better are presented. *Madame Vidot* is threatened with eclipse by *Madame Hoste*. *Jules Margottin* must submit to comparison with half a dozen new and formidable competitors, and in the rank of yellow roses *Maréchal Niel* has gone to the front rank already, and may occasion some indifference towards other roses of the same cloth. Exhibitions of roses afford to rosarians the best possible means of making fair comparisons of the merits of varieties, and useful notes on selection and culture; and seeing how rapid is the march of improvement in the most popular of all our garden flowers, a rose show almost merits the distinction of being considered of national importance; at all events, it bears immediate relationship to pursuits and recreations in which all classes join with fervour, and in its way and place sheds a light upon our domestic life, and for such and other reasons should be generally and generously supported.

The Birmingham schedule is a good one. Class A, for nurserymen, comprises five sections for seventy-two, forty-eight, twenty-four, twenty-four, and twelve respectively. Class B, for amateurs, comprises nine sections for forty-eight, eighteen, twelve, and six, and for residents within fifteen miles and four miles of Birmingham, and for others who have never before taken a prize. Class C comprises sections for new roses, moss, tea, and summer roses, bouquets, designs, and vases. Class D is for ladies only, and is instituted for a competition in dinner-table decorations. The entries were larger than they have ever been before, but many who entered made no appearance, owing doubtless to the hard winter and still harder spring having put them *hors de combat*. The competition, generally speaking, was spirited, and the flowers in the best collections were of very even excellence throughout, and that excellence decidedly above the average. At the Crystal Palace we could find faulty flowers in the best stands, not so here; but, on the other hand, in the midst of beautiful and perfect flowers we could find many of surpassing splendour, especially in the collections from Mr. Cranston, Mr. Keynes, Messrs. Paul and Son, Rev. P. M. Smythe, Mr. C. J. Perry, of Castle Bromwich, and Mr. Hunt, of Leicester. In the class for seventy-two (single trusses) Mr. Cranston, of King's Acre, Hereford, took first place, Mr. Keynes second, Messrs. Paul and Son third.

MR. CRANSTON'S FIRST PRIZE, SEVENTY-TWO.—Sénéateur Vaisse, Prince Camille de Rohan, Comtesse Chabillant, General Jacqueminot, this was an extraordinary sample of the General, diameter five inches, with solid globular centre, and huge shell-like petals, the colour nearly black; Charles Lefebvre, Horace Vernet, John Grier, Madame Heleze, Dr. Andry, John Hopper, Madlle. Bonnaire, Centifolia Rosea, very fine; Madame Brianson, King's Acre, good again, and quite a show rose; Peter Lawson, Black Prince, Maréchal Niel, one of the best ever shown, the colour rich; Madame C. Crapelet, superb in form and colour most beautiful, like the General, a shade or two darker than usual; Charles Verdier, America, a fine flower, much like Madame Willermoz; Triomphe de Villeceresnes, Mrs. Rivers, Claude Million, François Lacharme, Souvenir d'un Ami, Etienne Lecroisnier, Le Rhône, Madlle. Margaret Dombrain, a fine rose as shown in this instance; Deuil du Prince Albert, Jules Margottin, splendid for size, substance, and finish; Duchesse de Caylus, Joseph Fiala, five inches over without an eye, superb; Abbé Berleze, John Nasmyth, Louis XIV., La Esmeralda, Dennis Helye, Madame Knorr, Madame Boutin, Smith's Yellow, a lovely little rose, a sort of sculptured nugget; Eugène Verdier, Madame William, Vicomte Vigier, Devoniensis, Madame Hector Jaquin, Beauty of Westerham, a huge globular high-coloured flower, in the style of the General; Maréchal Souchet (Guillot); Duc de Rohan, extra grand; Margaret St. Amand, Le Baron de Rothschild, Gloire de Dijon, Madame Victor Verdier, Laurent Descourt, the finest dark rose in the show; Victor Verdier, sumptuous; Souvenir de Dr. Jamain, Madame Moreau, fine; Maurice Bernardin, Lord Macaulay, Madame Clémence Joigneaux, Madlle. A. Halphen, Beauty of Waltham, Baronne A. de Rothschild, Achille Gonod, Madame Vidot, Charles Margottin, Niphotos, Olivier Delhomme, Pætolus, Madame Rival, Auguste Vacher, most beautiful; Admiral la Peyrouse, Queen Victoria.

MR. KEYNES'S SECOND PRIZE, SEVENTY-TWO.—Madame Charles Wood, Abel Grand, very fine as shown in this stand; Alfred Colomb, Comtesse de Palikao, Madame Moreau, Madame Hector Jaquin, Pauline Lansezeur, Fanny Petzold, Fisher Holmes, Caroline de Sansal, Madame Boutin, Madame Caillat, General Jacqueminot, Sœur des Anges, Prince Henri de Pays Bas, Madame Knorr, Maurice Bernardin, Madlle. Margaret Dombrain, Baronne A. de Rothschild, John Hopper, quite a pancake; Madame Vignerot, Beauty of Waltham, Juno, Devoniensis, a lovely specimen, almost golden, and the buff shades peculiarly delicate; Madame Derreux Douville, Madame Pauline Villot, Comte de Nanteuil, Madlle. Marie Rady, Alba Mutabilis, Jules Margottin, Margaret St. Amand, very fine; John Standish, M. Berthe Levêque, Madame Julie Daran, Madame de MacMahon, like Madame Canrobert, but more colour; Duchesse de Morny, La Tour de Crouy, Sénéateur Vaisse, Hippolyte Flandrin, Madame Furtado, Clément Marot, Kate Hausberg, Madame Fillion, Prince de Porcia, Madame Hoste, showing an eye; Madame Victor Verdier, Souvenir d'Elise, Lacépède, Charles Rouillard, Lord Herbert, Souvenir de la Malmaison, Joseph Fiala, Alpaide de Rotalier, Gloire de Vitry, Pierre Notting, Victor Verdier, Dr. Andry, Semiramis, Madame Boll, Madame Canrobert, Anna de Diesbach, Xavi r Olibo, Princess Mary of Cambridge, Charles Lefebvre, Souvenir d'un Ami, Michel Bonnet, an extremely pretty rose; La Reine, Madame Amelia Halphen, this rose has a beautiful tinge of puce, and is the better for a little shading; Exposition de Brie, Madame Rival, Bernard Palissy, Madame Vidot, better in this lot than Madame Hoste.

In the class for forty-eight, the awards were, first, Mr. Keynes; second, Messrs. Paul and Son. In the class for twenty-four (threes), first, Mr. Cranston; second, Mr. Cant; third, Mr. Keynes. Twenty-four (single), first, Messrs. Perkins and Son; second, Mr. Joseph Jackson; third, Mr. Vertegans; fourth, Mr. Jennings. The principal exhibitors in the trade class for twelve were Messrs. Perkins, Mr. Vertegans, Mr. Pope, and Mr. Jackson, of Kidderminster.

MR. KEYNES'S FIRST PRIZE, FORTY-EIGHT.—Madame Charles Wood, Josephine Beauharnais, Madame Moreau, Madame Vignerot, Kate Hausberg, Margaret St. Amand, Alfred Colomb, Abel Grand, Charles Lefebvre, Alba Mutabilis, Prince Henri de Pays Bas, Madame Vidot, Madlle. Marie Rady, Caroline de Sansal, La Tour de Crouy, Pierre Notting, Pauline Lansezeur, Madame Berthe Levêque, Madlle. Margaret Dombrain, good; Dr. Andry,

Jules Margottin, fine; Souvenir de la Malmaison, Madame Knorr, Madame Victor Verdier, a glorious flower; Exposition de Brie, Madame Canrobert, Madame Boll, a saucer; Madlle. Pauline Villot, Madame Derraux Douville, Madame Fillion, Semiramis, John Hopper, Maurice Bernardin, Colonel de Rougemont, Fanny Petzold, Joseph Fiala, John Standish, Madlle. Bonnaire, Alpaïdo de Rotalier, Madame Furtado, Sénateur Vaisse, La Reine, Charles Rouillard, Princess Mary of Cambridge, Comtesse de Palikao, Beauty of Waltham.

The amateur's class comprised in all nine sections, and there were no less than thirty-four prizes awarded to amateurs in class B. Between the best and the worst of these there was of course a great difference, yet even the worst were meritorious, considering they had been grown under the very shadows of Birmingham chimneys, or at all events within the immediate influence of town smoke. In the schedules of the London shows there is no special encouragement afforded to Londoners to compete on terms that offer a chance of some gratification, for it is impossible the best roses that can be grown at Stepney or Brompton should compete fairly with the best that can be grown at Sydenham, Cheshunt, or in the soft air of Herefordshire. Our time was gone ere we could make a careful inspection of the town roses at this exhibition, but we saw them all, and must confess to a degree of surprise at their general good quality. We trust the town growers will be encouraged at Birmingham as long as the rose show shall continue to be an institution of the place, for it is no less important that floriculture should light up the homes of the people where they most do congregate, softening the hard outlines of town life and business with the beauty of flowers, and directing the minds of busy men to the great world of nature, with its exhaustless store of pleasures, instructions, and exalting thought. In the sections for amateurs, without respect of locality, the winners were Rev. P. Smythe, Solihull; C. J. Perry, Esq., Castle Bromwich; Mr. E. Hunt, Leicester; Mr. W. Brown, gardener to Mrs. Alston, Elmton Hall; and Mr. R. C. Chawner, Lichfield. In the sections for amateurs residing within fifteen miles of Birmingham, the winners were Rev. P. M. Smythe, Mr. W. Brown, C. J. Perry, Esq., and Mr. Cooper, of Moseley. In the sections for amateurs residing within four miles of Birmingham, the winners were Mr. Cooper, of Moseley; Mr. W. B. Mapplebeck, of Moseley; Mr. H. Lowe, of Edghaston; Mr. Winn, of Selly Oak; Mr. Fowler, of Erdington; and Mr. Arnold, of Moseley. In the section (twelve single trusses) for amateurs who have never previously won a prize for roses, the winners were Mr. J. P. Smith, of Coventry Road; Mr. John Parnell, of Rugby; Mr. E. Sarrington, of Leicester; and Messrs. J. F. and W. Lloyd, of Sutton Colfield.

THE REV. P. M. SMYTHE'S FIRST PRIZE, FORTY-EIGHT.—Madame Charles Wood, La Fontaine, Madame Boutin, Beauty of Waltham, supero; Margaret St. Amand, a had sample; Paul Desgrand, Madame Eugène Verdier, Madame Victor Verdier, Madame Caillat, Maréchal Vaillant, Louise Margottin, Professor Koch, Maréchal Niel, Baronne A. de Rothschild, François Lacharme, Caroline de Sansal, Alphonse Damaizin, Anna Alexieff, Louis Magnan, Prince Camille de Rohan, very fine; Baronne de Noirmont, Madame Craplet, Mrs. Rivers, La Reine, Charles Lefehvre, Charles Lawson, Vicomte Vigier, Madame Vidot, Duchesse de Caylus, La Ville de St. Denis, Sénateur Vaisse, Madame Clémence Joigneaux, Pierre Notting, Madame Knorr, a had sample; Madame Joseph Guyot, Gloire de Dijon, a fine sample, almost gold yellow; Lord Clyde, good; Gloire de Bordeaux, Maurice Bernardin, Anna de Diesbach, Madame Emain, Lord Macaulay, Céline Forestier, Duc de Rohan, Madame Boll, Duchesse de Morny, Comtesse de Chahrillant.

In the open class (C) there were two sections for new roses, namely, for best 24 sent out in spring of 1865-6-7, and for the best new rose sent out in spring of 1865-6-7. In the class for 24 the awards were—first, Mr. Keynes, of Salisbury; second, Messrs. Paul and Son, of Cheshunt; third, Mr. B. R. Cant, of Colchester.

MR. KEYNES'S FIRST PRIZE, TWENTY-FOUR (new varieties).—Madame Fillion, Comtesse de Palikao, Xavier Olibo, Belle Normande, Marie Baumann, Charles Rouillard, Alfred Colomh, Semiramis, Josephine Beauharnais, Madame Moreau, Abel Grand, Madlle. Marie Rady, Madlle. Margaret Dombain, Exposition de Brie, Dr. Andry, Fisher Holmes, Madame Hoste, fine; Prince de Poreia, Princess Mary of Cambridge, Comte Alphonse Serenye, a bold eye and loose petals; Margaret St. Amand, Monsieur Ponthriand, and two others, the names of which in our note-book we cannot make out.

In the class of best new rose sent out in spring of 1865-6-7, the awards were to Messrs. Paul and Son, of Cheshunt, first, for Alfred Colomh, and second, for Exposition de Brie; to Mr. Keynes, of Salisbury, third, for Margaret St. Amand, and fourth, for Princess Mary of Cambridge. The same varieties were shown by Mr. Cant, of Colchester.

In the class for six varieties of Moss Rose-buds there was a poor competition; this was one of the weak points of the show. Mr. Vertegans took second place, Messrs. Paul and Son third, Mr. Jackson fourth; the first prize was withheld, as none were thought worthy of it. The section for 18 varieties of Teas, Noisettes, and Chinas was scarcely satisfactory, judged by results; but there was one good collection from Messrs. Paul and Son, to which a first was awarded, and well they deserved it, for they were a very pretty lot, and the names were booked as necessary information for our readers.

MESSRS. PAUL AND SON'S FIRST PRIZE, EIGHTEEN TEAS, NOISSETTES, AND CHINAS.—Souvenir d'un Ami, Jaune d'Or, Madame Damaizin, Alba Rosca, Gloire de Dijon, Madame Maurin, Comte de Paris, Triomphe de Rennes, Caroline, Souvenir d'Elise, Devoniensis, Vicomtesse de Cézès, Madame Willermoz, Amahilis, Madame Falcot, Homère, Niphotos, Rubens. It will be observed that there were no Chinas of the Bengal class in this lot at all, and only one true Noisette, and that was Triomphe de Rennes. By many Gloire de Dijon is considered a Noisette, but it is always classed with the Teas, and one need not split hairs in a report.

In the section for twelve varieties of summer roses there was a thin show, and the second prize went to Messrs. Paul and Son, who put up the following:—

MESSRS. PAUL AND SON'S EIGHTEEN SUMMER ROSES.—La Séduisante (Alba), a flat-faced but pretty rose, the colours a mixture of pink and flesh, with tinges of salmon; Dr. Dieltheim (Gallica), rose shaded with purple; Blancefleur (Hybrid Provence); D'Aguessau (Gallica), rich crimson, large and showy; Unique (Provence), usually white, but in this case prettily barred, striped, and blotched with pink; Transon Gouhault (Gallica), deep but lively crimson, good form; Madame Soitmans (Damask) creamy white shaded buff; Columella (Gallica); Paul Ricaut (Hybrid Bourbon), rosy crimson, good form, one of the few of the summer roses that still keeps a first-rate place in competitions; Fillet Parfait (Gallica), white, with stripes of crimson, good; Louis Philippe (Gallica), dark, a fine rose; Botgavis (Hybrid Provence), the name is copied exactly from the ticket, we know nothing of it, and took note of its character; if we may trust to memory, ignorance is bliss.

This completes the classes for roses proper. Next week something must be said of the miscellanies and odds and ends, many of which were interesting and well worth a few notes before they pass into forgetfulness. The judges in the classes were the Rev. P. M. Smythe, Rev. R. Carter, Mr. Keynes, Mr. Cant, Mr. Gater (foreman to Messrs. Paul and Son), E. Tonks, Esq., C. J. Perry, Esq., Mr. William Dean, of Bradford, Mr. Shirley Hibberd. The usual and admirable rule was followed in appointing amateur cultivators to judge the nurserymen's classes, and nurserymen to judge the amateurs'. Let us hope that perfect justice was done; if it failed anywhere it was not for lack of attention and intention, and the judges had plenty of time for their work. S. H.

NOTES ON THE CRYSTAL PALACE ROSE SHOW.

This rose show forms one of the chief anticipations in the rosarian's calendar, and deservedly so, for in no place do the flowers appear to greater advantage than among so many kindred objects of taste and refinement, nor is there any place affording so much space and convenience for observation and criticism. Only one circumstance militates against its perfect success, which is, that it usually occurs a week too early to afford many growers an opportunity of exhibiting their flowers in full perfection; for, however large their collections, the possessors of cold deep soils are never up to the mark by the time the first show at the Palace occurs. And this brings us to a suggestion formerly thrown out by the writer, and since revived in several quarters, viz., that there should be a second show later in the season. There is little doubt that such an experiment would be attended with considerable pecuniary advantage to the Company, as well as encouragement to exhibitors, and the progress of the flower itself, many varieties, which are never seen in perfection in public, blooming the finest at a somewhat later period than others.

There is no doubt on the whole that, considering the date and the previous season, the show was a good one. There may have been fewer exhibitors and less extensive collections than of yore, but the flowers themselves were generally good—some, indeed, were of the first quality. Very many of the older varieties, such as Madame Knorr, Madame Domage, Jules Margottin, Madame de Cambacéès, the finest in foliage perhaps of all roses, and hardy to a degree; Auguste Mir, Souvenir de la Reine d'Angleterre, General Jacqueminot (this last always looking well),—appeared in the stands, showing their value as enduring kinds after the severe trial of the past double winter. Prince Léon also was in several boxes; this rose, although possessing fine points as a show rose, has been extensively banished from cultivation, owing to its uncertainty of growth: twenty buds may be put into as many stocks, and not half a dozen of them will take. Madame Furtado also was well done. This is another variety not to be depended on, otherwise it would be an unsurpassable kind. Madame Clémence Joigneaux was numerous exhibited, and was always fine. The same may be said of John Hopper, Madame C. Wood, and Xavier Olibo, which appears likely to make Prince C. de Rohan look to his regret. Maurice Bernardin, again, is still among the front rank. Indeed, the customary favourites of old and recent date were well represented, and I noticed in the stand of some provincial gardener a name I never saw before, equally euphonious with "Isabella Sprunt," namely, Anna Huck. The variety was worthy of the name. Many of the names were erroneously spelt. Even in the tallies of Paul and Son I remarked "Antoinetta" Ducher for "Antoine"; the lady for the gentleman.

The new rose, "Miss Ingram," raised, it is said, by Mr. Ingram, Her Majesty's gardener, and exhibited by Mr. C. Turner, struck me as resembling much "Mrs. Rivers," larger perhaps, and even more globular. It would have added much to the interest of the blooms had some of the shoots and foliage been shown with them, so as to give an idea of the growth and habit of the variety. If these are satisfactory, it will be an acquisition in a line of colour where few good and hardy roses are to be found.

Pot roses at this period of the year appear to be beneath the notice of professional competitors, and few other cultivators are in a position to exhibit in this class. What few were shown were not without admirable lessons in the carpenter's art, showing as much timber to stick out the branches as foliage itself. Yet what few were shown were not without instruction, being principally new varieties of the H. P's, proving that section to be as well adapted for purposes of forcing as Teas, to which the operation is commonly and most successfully applied.

In the amateur class, Mr. Hedge, of Colchester, appears still to carry all before him, and will probably remain without rivals in the larger classes till some rose-worshipping amateur likewise cultivates a number of plants equal in extent to an ordinary nursery stock. Hence we may learn what a necessary element number is in successful rose showing. Nevertheless, Mr. H.'s flowers are always put up with praiseworthy neatness and taste. It is much to be desired that these accessories to the stands were generally more prominently developed. The tallies in some boxes were almost illegible, badly written in pencil; in others the flowers were so cramped together that the cards with their names on could not be seen at all.

To exemplify what may be done by skill and judicious cultivation, the excellent twelve singles (amateur's), 1st prize, exhibited by the Rev. E. N. Pochin, Sibley Vicarage, deserve especial remark. They were twelve unexceptionable blooms, well set up, very equal in quality, and containing the best Xavier Olibo and one of the best Maréchal Niels in the show. The best yellow roses (mostly, by the way, below the average) were Maréchal Niel, L'Enfant Trouvé, Cloth-of-Gold, Triomphe de Rennes, Enfant de Lyon, Solfaterre, C. Forestier, Gloire de Dijon, Madame Margottin, now. From this list it will be seen there is little advance made in this section, nor is it much needed except in respect to hardness of constitution, unless we could obtain various shades of yellow in the hybrid perpetuals.

But, after all, a rose show, though one of the most charming spectacles that can delight lovers of beauty, as developed under the guise of flowers, is much of a delusion and a snare to many, as the gold eye-glasses and pencil-cases and embossed note-books in waiting round the tables find to their cost. A fine bloom does not always indicate a desirable variety, any more than a fine set of flowers indicates superior skill in the grower; both are materially modified by numerous adventitious circumstances known to the initiated, and must be merely considered as showing that any given exhibitor has such and such blooms to cut on a certain day. As an instance of this, I myself, on the Wednesday evening preceding the show, saw, in a ramble through Mr. John Fraser's rose quarters, much

finer blooms than any in his stands at the "Palace," and in a week later he will be in a condition to exhibit in all classes usually scheduled.

I do not know that I can utilize the subject better than by giving the names of the best varieties I noted on both occasions; in many cases they will be found to coincide.

At the Palace—Jules Margottin, Marguerite St. Amand, new, A 1; Madame Knorr, Madame C. Wood, John Hopper, Madame Clémence Joignoux, Marguerite Dombain, new, A 1; Marie Baumann, new, A 1; Madame Moroau, imbricated like the face of a double hollyhock, good, darkish; Alice Leroy, Leopold Hausberg, new; Joan Goujon, Thorin, new, promising, somewhat in the style of Crapelet; Charles Verdier, new, A 1; Madame Domage, Alfred Colomb, new, an improvement on Duo de Rohan; Xavier Olibo, new, one of the best, very dark flowers; Camille Bernardin, new; Victor Vordier, Duchesse d'Orléans, Comte de Nanteuil, Madame C. Crapelet, C. Lefehvre, and Madame Victor Verdier (these were not generally up to the mark, indeed, the first-named seldom is in true condition till late in the season); Madame Charles Wood, F. Laoharme, Pierre Notting, fine, dark plum colour; Claude Million, a dark hollyhock; William Griffiths, Lord Maoaulay; Kate Hausberg is not first-rate; La Ville de St. Denis, Exposition de Brie, new, not yet to be praised too much, I fear the centre; Maréchal Niel, Lafontaine, Marcella, new, not in condition, a singularly robust growing variety, with leathery petals, in colour resembling Nerium splendens; Madame de Cambacérés, remarked upon before; F. Louvat, purple bloom; Mons. Bonoenne, new, a darker Lord Raglan; Madame D. Douville, not up to the mark on this occasion; Madame Furtado, a magnificent variety; Princess of Wales, F. Laoharme, Antoine Ducher, new; Gloire de Ducher, new, very large, but coarsish; Charles Rouillard, new; Annie Wood, crimson, a first-rate novelty; Comtesse Palikao, François Treyve, new; Chevalier Nigra, new, A 1; Josephine Beauharnais, new; Charles Verdier and Abel Grand, new, light kinds, A 1; Felix Genero, new; Semiramis, new, good, light; Thérèse Levet, new; Souvenir de William Wood, new, dark. These varieties are all good, though they by no means exhaust the meritorious kinds.

The varieties I specially marked at Mr. J. Fräser's, omitting most of already established reputation, were Madame Baptiste Desportes, Madame Fillion, Abel Grand, Comtesse de Palikao; Charles Rouillard, Alba Mutabilis, Bertha Levêque, President Mas, I fear this will not turn out so fine as expected; Prince de Porcia, good garden rose; Antoine Ducher, hue and habit of Madame C. Wood; Souvenir de Madame Boll, Thorin, Madame Rival, after Auguste Mie; Madame E. Appert, Chevalier Nigra, Margaret de St. Amand, Madame A. Halphen, Charles Verdier, between Victor Verdier and John Hopper, smooth wood; Monsieur Noman, Madame Bellenden Kerr, an improvement on Bonnaire, and stronger; F. Treyve, Horace Vernet, Eugène Scribe, imbricated; Napoleon III., Madame Villeboisnet, Paul Verdier, Belle Normande. It will be seen these are all roses of the past three years; the exigencies of space require older kinds to be postponed till another occasion, as must also be the descriptive consideration of their shapes, colours, habits of growth, and general behaviour.

London Road, Clapham, July 2nd.

W. D. PRIOR.

GLEANINGS FROM THE R. H. S. ROSE SHOW.

Of all the flowers that are cultivated in our gardens, the rose is the most popular. It is everybody's flower, no matter what country, creed, or age. Yes, from childhood to manhood, from manhood to age, the rose is alike the favourite flower. To those even who are indifferent to the science of gardening the rose is a spell, a wonder, a thing of beauty, for it combines in its many qualities two of the greatest essentials in the attraction of flowers—fragrance and brilliancy of colour. It is most proper that it should be styled the "queen of flowers," as, from the earliest period of cultivation, it has been the theme of the poet's song, and the noblest flower in the garland of festivity and honour. Having within the past week visited the great rose show at the Horticultural Gardens at Kensington, some thoughts have been aroused within me respecting their culture, the reading of which may possibly expand in other minds to some things in relation to them far more useful than here hinted.

As we proceeded with our observations on the comparative excellencies of the flowers, we were particularly struck with the different degrees of colour in the same variety of flowers as exhibited by the various growers. For instance, some of the light-coloured flowers had assumed a somewhat deeper hue than naturally belongs to them, so as to be almost identified with other varieties, and yet this was not the result of their blooms being on the decline; quite the contrary. This is, then, a matter of some importance to those who are selecting roses. We are induced to ask, To what are we to attribute this variation in the shades of colour? We do not believe that it is influenced by soil, but it is caused by the means adopted for securing the blooms fit for exhibition, such as too much shading, which would rob it of its proper purity of colour; and then, on the other hand, the feeding of the roots with repeated doses of liquid manure, which would impart to them deeper shades of colour than we are accustomed to. I remarked to an exhibitor on the morning of the show on the dissimilarity in the shadings of some of the light roses in the several stands, and he concurred in my observation that the differences were owing to differences of treatment rather than to differences of soil. The Tea scented varieties did not present this variation, because the blooms are in the majority of instances cut from plants grown in pots, and have pretty nearly the same treatment everywhere.

Since my visit to the exhibition, a question was put to me as to the means by which the splendid blooms as exhibited were obtained. Not being quite prepared for the question, I did not afford so direct a reply as I am enabled to do on more mature consideration. On a close inspection of the numerous boxes of blooms, you could, without seeing the names of the exhibitor or having a knowledge of the class in which they competed, detect at once whether they were the production of an amateur or a nurseryman. There may be exceptional examples where the amateur may possess more than ordinary resources for an extensive cultivation. The spectator in viewing the magnificent display must not suppose for a moment that they have been selected from among a few hundred of plants; no, but from among thousands of all ages and sizes. In making choice of his blooms, the grower has the advantage of traversing along whole rows of the one and same variety, that he may select half a dozen flowers. In so doing he must stumble on many flowers and plants of an inferior quality. His best flowers are not obtained from plants that produce the greatest

quantity of bloom, but from very young heads or bushes, probably those which were only budded the year previous, and may in that case only have given two or three blooms, but those in every way remarkable for size and richness of colour. Then we have again to consider the means employed, and the sacrifice of buds often resorted to that extraordinary production may be obtained. It is so with all florists' flowers intended for exhibition—the pink, dahlia, chrysanthemum, &c. The inferior buds are removed, and only those that promise a vigorous development are allowed to remain, the number being in proportion to the strength of the plant. Then there is the after care of shading, watching for insects, &c., and all this extra labour is only bestowed on those flowers that are intended for competition.

There is another consideration in relation to successful rose culture which must not be overlooked, and that is the nature of the soil and the locality. It will be observed that wherever nurserymen are eminent for the growth of any particular class of hardy trees or shrubs, or any other kinds of out-door plants, that the spot on which the nursery is located is generally favourable to their thriving. As an illustration, take our principal nurserymen who are famous for the successful cultivation of hardy rhododendrons, azaleas, &c. So it will be found with the rose. The most of the cut blooms, both at Kensington and the Crystal Palace Rose Show, were the productions of growers residing a great distance from the metropolis, they having fixed on localities that are congenial to the well-doing of this glorious flower. In selecting standard roses, amateurs are too anxious to obtain plants with large heads, regardless of their age, present effect being their object; and what follows in the next season from such a selection? Why, general disappointment in regard to size and substance of bloom, though there may be plenty of it. A few years since I purchased some standard roses of a nurseryman who was celebrated for their growth. This happened to be about the middle of the month of February; the consequence was, that their stock had been greatly exhausted during the previous autumn, so that of the sorts I required there remained very few, save those which were budded the previous summer. From them I made my choice. The bed in which they were planted had been previously well prepared, by trenching it to nearly three feet in depth, intermixing with the soil plenty of decayed manure. In this their roots luxuriated freely; they were pruned back to about two eyes, and the same year, although planted so late as February 14th, they produced some remarkably good blooms, especially during the autumn months.

I must not forget to mention that my preference in selection was given to those that were budded on briars, and which possessed clean healthy stems. By removing the soil round them to the depth of several inches, and adding some good rich compost annually in November, they have gone on growing and thriving satisfactorily. My advice, then, is, never select old bushes in preference to those more recently budded plants, that is if quality is your object instead of quantity of flowers. I am often surprised that there are not more beds of dwarf roses grown, either budded on the Manetti stock or grown on their own roots; thus cultivated they make extraordinary vigorous shoots and fine blooms in abundance. I was forcibly reminded of this omission in the garden culture of the rose by witnessing, at Mr. Mickle's Nursery at Folkestone, many thousands of dwarf roses grown on the Manetti stock. Not only did they produce superb shoots, but also flowers that well matched their vigorous growth, while the standards grown in the same soil were meagre in comparison. I am further favoured in my advocacy of a more general culture of the dwarf kinds by what I saw in a visit to the beautiful but neatly kept grounds of Madame Stevens at Roehampton. This happened just after the severe frost we experienced last May, and I was astonished to find the beds of dwarf varieties, of which there are many planted in the roseries, not in the least injured as compared with the standards. In these remarks do not let it be supposed that I mean to infer that roses planted in the same soil for a number of years will not produce vigorous growth and quantity of blooms, because we have plenty of illustration in the affirmative throughout the breadth and length of our land.

In closing this paper, let me be understood by saying that there are some sorts of roses that are exceedingly beautiful when cultivated in the garden, but are totally unfit in the absence of size (though possessing every other claim) to make any display in an exhibition stand. If you wish to give exclusive attention to the growth of roses for competition, then select those varieties that give you large full flowers. JOHN F. McELROY.

MY ORCHID HOUSE.—No. XII.

THE AERIDES.

If I were to hazard an opinion upon the subject, I should certainly say that no orchid house, however well stocked in other respects, could be considered complete unless it contained several species of this magnificent genus. I fancy, too, that our exhibitors of large collections would experience a very great difficulty in getting such good collections as they now do were they deprived of it; for from what other source could we obtain such graceful habited plants, and such immense spikes of beautifully tinted wax-like flowers as we have in the Aerides? Moreover, very few plants at present known would be able to supply the delightful fragrance which pervades the orchid house during the early summer months, when the claims of this genus have not been neglected, but recognised and encouraged. We are told that the plant we have under consideration derives its generic name from the supposition of its being able to absorb its nourishment and support from the atmosphere alone. Undoubtedly it is endowed with that power to a certain extent, and in all probability as much as any other genus of orchids. To grow and flower the Aerides successfully, it will require what I may call a generous temperature of say 75° to 85° through the growing season, which will commence about April and should terminate by the end of September at the latest, if an abundance of bloom is expected or desired the following season. The amount of solar light we obtain in this country in the autumn is not sufficient to properly mature the growth made after September; and those kinds which flower rather late should be pushed slowly as soon as their beauty is past, to give them every oppor-

tunity of going into rest early. If the plants are all right at the roots, they will require plenty of water; and after the flowering is over a gentle syringing overhead once a day will be decidedly beneficial. A temperature of 60° to 70° through the resting season will carry them safely, with very little moisture at the roots at the same time. As the plants have no storehouse in the shape of thick fleshy bulbs to sustain them through that period, they must not be kept quite dry. The *Aerides* can be grown in pots or baskets, at the choice of the cultivator. It does equally as well one way as the other. If pots are used, they should be those with perforated sides, to enable the roots to derive every possible advantage from the atmosphere, and be well drained. As to soil, either good peat full of tough fibre or sphagnum will grow the plants well. I prefer the latter mixed with one-third part of cocoa-nut fibre, particularly as good sphagnum is generally speaking expensive. Propagation is effected by taking off the side shoots after they have thrown off two or three roots. They are to be potted in small pots, with a neat stick, to keep them firm. The undermentioned half-dozen species will not fail to be satisfactory:—*A. affine* and varieties, *A. crispum*, *A. Feildingii*, *A. Larpentæ*, *A. odoratum* and varieties, and *A. virens*.

GEORGE GORDON.

GARDEN CULTURE OF THE CHRYSANTHEMUM.

Although the Chrysanthemum is quite hardy, and will grow in almost every situation and soil, yet, inasmuch as it is a native of a land where the thermometer stands at 100° Fahr. in the shade during the months of July, August, and September, there can be no doubt that for anything beyond the most ordinary purposes a southerly aspect, as well as a prepared soil, are very desirable. When vigorous foliage and fine flowers are required, the soil should consist of two-thirds loam and one-third rotten stable manure, mixed with river or silver sand, to assist the drainage. This compost, if allowed to remain in ridges during the winter, will be in a proper condition to receive the plants in spring. Some persons prefer planting the suckers or offsets in autumn, but to this there are many objections, as they are liable not only to be eaten off by slugs and other vermin, but destroyed by frost, and if not actually killed, are so crippled as to be incapable of making handsome plants. When the plantations are made in April and May, no injury is to be apprehended from any of these causes, the temperature at this time stimulating a rapid growth.

Chrysanthemums in borders can be planted in double or single rows, thus:—

Pompons, on account of their height, being placed in the front. The number of rows may be increased according to the space devoted to the purpose; but, in order to ensure healthy foliage, and allow a free circulation of air, the distance between each plant should never be less than three feet. The intervening spaces will be filled up by the foliage long before the blooming season.

In forming such a plantation much care is required not only in the harmonious selection and arrangement of colour, but also in the gradual elevation or height of the plants, so as to ensure a pleasing *coup-d'œil* in November; this may easily be accomplished by planting each row with varieties of the same natural growth, and if any irregularity should occur during the summer or autumn, it can be remedied by careful training. It should be borne in mind that healthy spring-made plants, or suckers, produce larger and finer flowers than pieces of old roots, and that one, or at most two, are quite sufficient to form a large bush. Towards the end of June a stake should be put to every plant, each row differing in height according to its order; thus those in the second row should be six or nine inches taller than those in the front, and those again in the third row six or nine inches higher than those in the second. The main stem of the plant should, from time to time, be firmly secured during the growing season, the laterals also being kept in place by tying, and any unsightly branches removed. In September, the buds usually appear, and as one large flower upon each branch is preferable to several small ones, and amply sufficient to ensure a fine head of bloom, the disbudding should at once be commenced. Three or four flower-buds always terminate each branch, but only the crown or middle one (if perfect) should be left; all the others must be carefully removed. This practice was adopted by the Chinese upwards of a hundred years ago. Rumphius, in the "Herbarium Amboinese," tells us that, by this method, the flower was increased to the breadth of a man's hand.

The beauty of the foliage, and size of the blooms, may still further be increased by giving liquid manure frequently during September and October; this, however, must be discontinued as soon as they begin to expand.

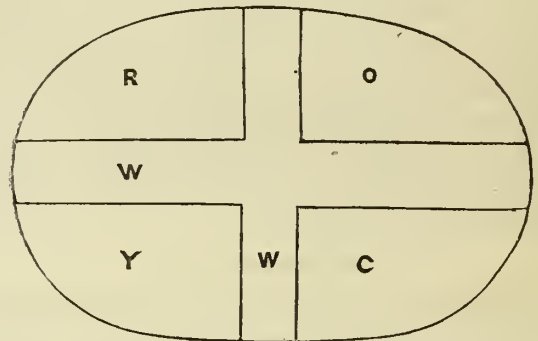

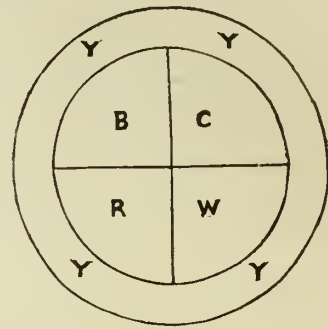

The success attending Mr. Broome's labours may be cited as an illustration of what may be accomplished in open garden cultivation even in the midst of the city of London itself; and his perseverance and zeal, in spite of smoke, fog, and other obstacles, have been rewarded by seeing the high appreciation in which his flowers are held by the thousands of visitors who, during the month of November, throng the Inner Temple Gardens.

The following varieties are adapted for open-air culture:—

Abbé Passaglia, Albert Helyer, Albin, Alfred Salter, Alma, Anaxo, Annie Salter, Ariadne, Attraction, Auguste Mie, Aurea Multiflora, Beauty, Bella Donna, Bernard Palissy, Beverley, Bixio, Bossuet, Cardinal Wiseman, Cassandra, Cassy, Cherub, Chevalier Domage, Christine, Cloth-of-Gold, Daphne, Defiance, Deucalion, Diadem, Dido, Don Quixote, Dr. Brock, Dr. Maclean, Dr. Rezas, Eve, Fair Rosamend, Florence Nightingale, Garibaldi, General Slade, Golden Ball, Golden Beverley, Golden Christine, Golden Cluster, Golden Hermine, Golden Queen, Golden Trilby, Goliath, Her Majesty, Hermine, Hercules, Jardin des Plantes, Jenny Lind, Julia Grisi, Julie Lagravère, La Bello Blonde, Lady Harding,

Lady Slade, Le Prophète, Little Harry, Lord Clyde, Lord Palmerston, Lord Ranelagh, Lord of the Isles, Louis Barrière, Madame Domage, Madame Poggi, Miss Slade, Mr. Brunlees, Mr. Murray, Mr. Wynes, Mrs. E. Miles, Mrs. Haliburton, Mrs. W. Holborn, Mulberry, Nell Gwynne, Nil Desperandum, Novelty, Pelagia, Pink Pearl, Prince Albert, Prince of Wales, Prince Alfred, Princess of Wales, Princess Louise of Hesse, Princesse Marie, Prometheus, Psyche, Queen of England, Queen of Lilacs, Quilled Beauty, Saccoi Vera, Sir S. Carey, Snowflake, Striped Queen, Sulphurea Superba, Talbot, Temple of Solomon, Trilby, Triomphe du Nord, Vesta, Virgin Queen, White Christine, White Queen, Zephar; with many others.

Pompons may be advantageously planted in many ways, either, as already mentioned, in front of large flowering varieties or in beds by themselves, by which means they may be made as ornamental in October and November as geraniums and verbenas are in summer and autumn. The size of the beds must, of course, be regulated by the amount of available space and the number of plants intended for the purpose. Their shape may be geometrical or otherwise, as taste and fancy dictate. Circular or oval beds with rising centres will be found very effective.

DIAGRAMS FOR BEDDING CHRYSANTHEMUMS.

The letters in the diagrams denote colours. B, blush; C, crimson; O, orange; P, purple; R, red; W, white; Y, yellow.

It should always be borne in mind that the general effect depends as much upon the harmony of colour as the masses of bloom.

Plantations should be made in early spring, each root being set at least twelve or eighteen inches apart. When the plants are about eight inches high they should be stopped—that is, the head of the leader taken off, to stimulate the growth of the lateral branches, and these when six inches long should be pegged down in the same way as the heliotrope, verbenas, and other bedding plants. This operation of stopping should be repeated from time to time until the beginning of July, when the branches must be carefully arranged, so as to leave no vacant spaces, the whole bed being in this manner covered with foliage. During the summer the plants must have a liberal supply of water, for if they are once allowed to droop it will be found difficult to recover them. Occasional syringing in the evenings will be of great benefit. In autumn the uneven branches should be regulated in order to ensure an equal surface of bloom. During the month of September liquid manure will be needed once a week. Mr. Dale was the first successfully to adopt this style of plantation, and his bedding Pompons in the Middle Temple Gardens have become the annual admiration of a multitude of visitors. The following varieties are most suitable for the purpose.

White or Blush.—Argentine, Cedo Nulli, Fairest of the Pair, Louiso Piton, Modèle, Madamo Eugène Demage, Miss Talfourd, Turris Eburnea.

Yellow or Orange.—Aigle d'Or, Aurore Boréale, Danaë, Drin Drin, General Canrobert, Golden Aurore, Golden Cedo Nulli, Golden Circle, Mr. Astie.

Rose or Purple.—Adonis, Durnflet, Florence, Hélène, Lilac Cedo Nulli, President Decaisne, Rose Pompon, Salomon, Trophée.

Red or Crimson.—Bob, Brilliant, Capella, Dr. Bois Duval, Madame Pepin, Miss Julia, Mustapha, Riquiqui.—SALTER on the Chrysanthemum.

PREPARING STRAWBERRY PLANTS FOR FORCING.

There are different methods adopted by different people in preparing strawberries for forcing; but there is only one that recommends itself to the notice of those who really desire to be successful in forcing this delicious fruit. This plan I propose to give in detail, to assist those who may desire some information upon the subject, after which I shall briefly refer to methods of preparation which some other cultivators adopt.

In the first place, I may state that, so far as my own observation goes, I find that strawberry runners are exceptionally late this season, and in the majority of cases I have seen they are very weak; consequently those who pot up plants by hundreds will need to use great vigilance and caution in securing the earliest and strongest runners. But the scarcity of plants should not tempt the cultivator to use any but the first plants made upon the runners, those formed at long distances from the parent plant being generally weak, and sometimes proving to be barren. As soon as sufficient runners are formed, get ready some soil consisting of three parts loam to one part leaf-soil. I prefer a rather heavy soil in this stage, because it will retain moisture much better, and so reduce the labour of watering. Let the soil be sifted and placed upon the potting bench; then fill a number of 60-sized pots, placing them on the hand-barrow as the work progresses. When the barrow is full, take it to the beds where the pots are wanted. Having selected the runners, place a pot under each, and secure it to the middle of the pot either by the weight of a small stone, or else use short pegs to keep it in its place; and in a short time they will emit roots. I can give no information as to the numbers required, as in some cases they are potted up by thousands, while in others a few hundreds will suffice. But I may remark that a few more than the actual number required should be got ready, as there are generally a few failures, either from weak plants or deformed crowns; and I may give a word of caution to the inexperienced reader against preparing more plants than he can house and care for properly, as it is a folly to prepare a thousand plants when the forcing room will only admit of five hundred; for when strawberry plants are properly prepared for forcing, they entail an immense amount of labour, and unless they are well done (especially for early work) they are sure to lead to disappointment. Having laid sufficient plants in the pots, and each one secured in its place, all those runners extending beyond the plants set in the pot should be pinched off, that all the strength may go to the plant it is desired to save. This done, the cultivator's only care for them for the next three weeks consists in keeping the soil in the pots well watered, that the roots may have every chance to grow, and to fill the pots full of roots as soon as possible. With the soil above recommended, watering must be attended to at least every alternate day, and in dry hot weather they would be the better for a good soaking every night. There can be no doubt it would materially assist the formation of roots in the soil in the pots if the pots could be plunged to their rims in the bed, as then the pots would not be exposed to the drying influences of sun and wind; and there can be but one opinion that the more moisture we can retain in the soil the more speedy will be the formation of roots. With ordinary care in watering, plants so treated will generally fill their pots full of roots in three weeks; that is, if the plants in the first instance are moderately strong. The young plants may then be severed from the parents, and be taken to some shady spot under a wall or fence. With abundance of water for a week in this spot, they will recover from the check received, and in a few days after will be in a fit condition to be placed in their permanent pots. But this part of their management I must leave for the present, while I detail other methods of preparation.

The method now to be described is practised by a few cultivators, and is upheld by them on the score that it is the most simple and speedy; which I do not deny; but I do say that it is not the most satisfactory, according to the results I have seen obtained from it. Those who practise this method use no small pots, but prepare in the first instance the pots in which it is intended to fruit them. The pots are well crocked and filled with earth, and then taken to the beds to have the runners placed upon them, exactly as detailed above for the small pots. They are watered, and of course properly cared for; and when it is thought that the plants have made sufficient roots to support themselves, the runners are cut away, and the pots taken to more convenient quarters for watering. In this plan, as will be seen, there is no more work of potting after the plants are once laid on the soil; and this will no doubt find favour with some of our readers. But the reader must remember plants so managed are by no means equal to those first raised in small pots and then potted, as when the young runners are merely fixed upon the soil to make the best headway they can, the crowns of the plants are often badly placed, sometimes almost

out of the soil, and sometimes with the crown completely buried; and these are all mistakes that must be guarded against by those who wish to excel in strawberry forcing.

Another plan is to specially prepare a small spot of ground on some warm border by the addition of loam, rotten dung, and coarse sand. This, well mixed with the staple soil, will prove eminently favourable for young strawberry plants. The ground being got ready, the earliest and best rooted runners are planted out on it twelve inches apart each way. They are protected during severe weather in winter, and potted up for late spring crops. By such management I have myself secured fine plants in the spring, and taken a moderate crop of fruit from them. But such plants as these are not adapted for early forcing, as if put into a strong heat they run out to leaves, with but little flower and no fruit worth gathering.

I have now detailed the principal methods by which different people secure a stock of plants, and now I must leave the reader to choose for himself, while I return to complete the details of preparation of the plan just noticed.

For potting those plants raised in small pots (or indeed any that are required for early forcing), the soil should consist of equal quantities of mellow fibrous loam and rotten dung from an old hot-bed that has lain by for twelve months in a heap. To these ingredients add one-third of coarse sand (the sharper the texture of it the better), and to every barrow-load of this soil add about one gallon of soot. Let the whole be well mixed, but not sifted; only broken up with a spade. The pots should be clean and dry, and well drained. I like a 32-size pot; and indeed they are large enough for all ordinary purposes, for setting aside the bulk and weight of larger pots, I am satisfied that plants well grown and judiciously forced in a 32 will produce results equal to those in a size larger. The principle to be aimed at in preparing the plants is to secure an early growth; that is to say, to give every possible encouragement to the plants to fill their pots full of roots before the cold nights and drenching rains of autumn set in. For unless they have done this, a weak succulent growth only is obtainable in the autumn, which every good gardener knows is not conducive either to health or fruitfulness. But with plants that have completed an early growth, with stout and prominent crowns exposed above the foliage, the chances are far more favourable, and the plants quietly go to rest with ample time to mature themselves, and to secure a season of dormancy before they are required for a more active life.

In potting there are two essential features to be observed. The first is to place the crown of the plant well up above the soil; the next is to make the soil firm and close round the roots. The object of placing the crown well up above the soil is to expose it to the action of the elements, that it may get plump and thoroughly ripened, which will greatly assist in the formation of the flower spikes for the crop. This is a process not visible to the cultivator; but there can be no doubt that when plants are in a high state of cultivation, and all the organs full of health and vigour, that when going to rest there is a process taking place in the interior of the plants, where the essential organs of fructification are formed in embryo ready to be developed when a suitable temperature is given them. Admitting this, we shall at once understand how important it is that we should secure an early growth in our strawberry plants for forcing, that there may be time for them to complete one of the principal processes whereby we secure a crop, and we shall understand, too, more readily the cause of failures in weak immature plants. The object of making the soil firm round the roots of the plants is to make sure that all the soil is well permeated with roots. That is to say, in a firm soil the roots will expand and distribute themselves as they work outward from the plants, and so fill the whole mass of soil as they push towards the sides of the pots; whereas, if they are potted lightly the roots will start out at once to the outside of the pot, and the interior of the ball of earth will scarce have any roots at all, and will remain so until the plants are taken in to force, when a little excitement starts the plants again into growth, and the roots also. They have then the unexhausted soil in the middle of the pot to work in, which starts the whole plant again into a vigorous growth, to the utter consternation of the cultivator, who does not want leaves but flowers. The result is generally barren but leafy vigorous plants that more nearly resemble cabbages than strawberries. The object of the cultivator should be to secure *pots full of roots*, and this is particularly important for early crops; for if the pots contain at the time they are taken in to force any unappropriated soil, the roots will work into it too vigorously, and the result will be a mass of leaves instead of bloom. Having potted the plants and given each a good soaking with water, stand them on a firm hard bottom fully exposed to all weathers until the end of October, when they should be taken under cover. Keep the plants abundantly watered until the end of September, when it may be slightly diminished. They should be occasionally weeded, and all runners picked off as they appear.

J. C. CLARKE.

CULTIVATION OF THE TURNIP.

Turnips are frequently a cause of disappointment in small gardens, but where there is a good open space, there is not a more useful or profitable crop. They do not require a rich soil, and will come well without manure on land that was manured for the previous crop; at the same time heavy manuring may be practised to advantage. They are hardy things; they follow nicely on the heels of summer things, such as potatoes, peas, &c., and may be sown at almost any season of the year. The use of liquid manure is strikingly exemplified in the culture of turnips, and on small farms—where improvements are not as rapid as they should be—it would always pay well to give the ground a good soaking with liquid manure, and then sow swedes at once. But as liquid manure is not everywhere obtainable, the good old plan of digging in good stable manure cannot be superseded. They would only want hoeing and thinning afterwards, so as to leave them finally at nine or ten inches apart, and a heavy crop would be certain; liquid manure renders this crop additionally profitable, and it is one that exhausts the land as little as any.

In garden culture, the first sowings may be made in February, either on a warm border or on a gentle hotbed, and they will come in for use during April. Early White Dutch and Early Stone are the best for this purpose. After the first of March, they may be sown at any time till the end of September. But for the winter supply, which is the most important, because the wether legs are then prime for them, a good breadth should be sown at the end of July, and if possible another at the end of August. These will come in during winter and early spring, and furnish greens as well as bulbs, at a time when both are prized. For all general purposes the Common White, Large Round White, and Early Stone are the best, but for allotment culture, swedes are the most profitable, and most generally useful, especially where there is a little live stock to be thought of. It is best to sow turnips in drills, dropping a few seeds along the drill twelve inches apart; but they do very well broadcast, and should be sown thinly, just after rain. When the plants have three or four leaves each, thin them out to ten or twelve inches asunder, and give the ground one good hoeing through. After that, the turnips will spread and choke all weeds, and need little further attention, except during drought, when they should have plenty of water or liquid manure. Just before Christmas, it is as well to take up a lot of the best bulbs, remove the tops, and store them in sand, though if the winter is not very severe, they will fight it out in the open ground. Since turnip-greens are much valued as a spring vegetable, I would suggest the use of swedes in gardens expressly for the purpose, for the green tops are more sweet and tender than any of the other kinds. Early in December, get some of the largest bulbs, and on a piece of rich mellow soil draw drills a foot apart, pack the swedes close together along the drills and soil them over with ashes six inches deep. They will sprout through the ashes, and may then be cut off close to the bulb; the ashes being clean, are easily removed for that purpose, and any uncovered and not cut must be covered over again. This plan will give you a supply of the most delicate vegetable you can eat from the end of January to the end of March, especially if some were got in a month or six weeks earlier, expressly for a first crop. Ordinary turnip-greens give no idea of the delicacy of these blanched stems, which are equal to asparagus, and invaluable when greens are scarce.—*Profitable Gardening by Shirley Hibberd.*

TREATMENT OF PINE SUCKERS.

Suppose a quantity of suckers to come under treatment about the end of August or beginning of September—the time when suckers are generally in a fit state to be taken from plants that have produced the summer supply of fruit—let them be carefully detached from the parent plants, cut their rugged base smoothly off with the knife, and remove with the hand those short scaly leaves which cluster round their base, and under which appear the young roots. The leaves should not be removed any higher up than where these young roots assume a brownish hue. As this operation is proceeded with, the suckers for convenience should be classed into two lots, the smallest and the largest being placed by themselves. The largest set, presuming that they are strong and healthy, are to be potted into eight-inch, and the smallest into six-inch pots. The pots, if not new, should have been well washed both outside and inside. The crocking should be efficiently performed with rather finely broken crocks with all dust sifted out of them. They should be arranged in the bottom of the pots to the depth of one and a half inches in the six-inch, and two inches in the eight-inch pots. Over the crocks should be placed a thin layer of dry moss or the most fibry part of the loam, and over all a sprinkling of fresh soot, which acts as a barrier to worms and affords a stimulant to the plants.

In potting the suckers, place them sufficiently deep in the pots to keep them steadily in their places; press the soil about them as firmly as it can be pressed with a blunt-pointed piece of wood, and leave it about three quarters of an inch from the rim of the pots, that there be no difficulty in watering them when necessary. It being presumed that a pit was previously made ready for their reception, they should be plunged at once to the rim of the pot; and should the bottom-heat be derived from leaves or tan, or both, and not likely to exceed 85°, the plunging material may be placed firmly round the pots; but if the heat is likely to exceed 85°, let the material be placed lightly and openly round them. Let the plants be arranged, as previously directed, according to the structure of the pinery, and in doing so avoid crowding them together, the consequence of which is to draw the young plants up weakly, and to make good plants of them afterwards is almost impracticable.

They must now be shaded from the sun during the brightest part of the day for ten or fourteen days, or, in fact, till it be found that they are making roots. In the afternoon, when the shading is removed, they should have a gentle dewing overhead through a very fine rose. The shading and dewing must not be abruptly discontinued, but by degrees, and entirely given up whenever the young roots can be discerned at the outside of the ball of soil. Then they should have a watering with water at 80°, sufficient to moisten the whole ball. After this they soon begin to grow freely, and air should be given early in the day when fine. A good supply of air, with as much light as possible, and a moderately moist atmosphere, with a very sparing use of the syringe, will prevent them from making a weakly-drawn growth.

From the time the suckers are potted the great object is to obtain a compact sturdy growth as one of the principal points of future success, and which will enable the plants to go through the rigours of winter with

impunity. This is dependent chiefly upon free exposure to light, a good supply of air without draught, and a moderate amount of heat and moisture both at the roots and in the air.

The night temperature for September should range from 65° to 70°, with 10° to 15° more for a while when shut up in the afternoon with sun-heat. After the middle of October the heat should be 5° less, and it should gradually decrease till, by the middle of November, it is 55° by night and 60° by day. During October the bottom-heat should not range higher than 75° to 80°; and for the three following months I consider 75° quite sufficient to keep the roots healthy through these dull months. In olden times, when every sucker potted in autumn was deprived of its black and lifeless roots in spring, it was considered that pines lost all their previous year's roots in the common course of nature. But there is no doubt whatever that the real cause of the evil arose from the common rule of renewing the beds in which the pines were plunged at the fall of the leaf, the consequence of which was a degree of bottom-heat which pine-roots cannot bear and live. The good pine-grower of the present time is not satisfied if, when September-potted suckers are shifted in early spring, their roots are not white and full of life, instead of black and shrivelled.

Under ordinary circumstances I would recommend that the suckers now being treated of should be kept quiet from the middle of November till the middle of February, and not encouraged to grow. To rest them thus a temperature of 55° is preferable to 60°, unless during very mild weather, but 60° should never be exceeded. The atmosphere should be dry rather than otherwise; and I have very rarely found that, when grown on a bed of leaves and tan, during these months they ever require any water at the root. The tan in which the pots are plunged is generally moist enough for the maintenance of pine-roots in a healthy condition, and the soil in the pots is regulated as to moisture at this season by the state of the plunging material. Where the bottom-heat is supplied with hot-water pipes in air chambers or tanks, the plants may require an occasional watering; but with the bottom-heat that I have named the waterings required will be very few indeed. With young stock there is little danger of their fruiting prematurely from being kept dry, if all else be right; and in all other respects it is much the best practice.

When the thermometer rises above 60° a little air should be put on, always at the highest point of the pit or house. But, unless during a continuance of dull damp weather, the temperature should not be purposely raised in order to admit of giving air. In most pineries there is a sufficient amount of circulation going on in the atmosphere through the laps of the glass and other chinks to render systematic air-giving, with the low temperature and dry atmosphere that I have recommended, unnecessary. It is therefore during only sunny days, when the heat is raised, that air-giving must be carefully attended to during the season of rest.

Under ordinary circumstances this is the winter treatment to be recommended as that which will give succession plants in the most robust and healthy condition in spring, and that can be grown into the very best fruiting stock by the following autumn. Scarcity of intermediate plants may, however, in certain cases, render it desirable to considerably increase the size of the plants in order to gain time. When such is the case, they should be kept gently on the move all winter by keeping the temperature at from 60° to 65°, with a little more moisture at the root than has been recommended. The highest temperature named should be given during the brightest and calmest weather, when it can be secured without anything like violent firing, and during weather the reverse of this the lowest is much the safest. This winter growth can only be pursued with success when the pineries are light and fully exposed to every ray of sunshine that can possibly be had. Otherwise the plants will become drawn and weakly, a condition which will more surely than any other defeat the object in view. It is only when there is a scarcity of good succession plants that I would advise these autumn suckers to be pushed on with the view of resting them in April and May, in order to start them for supplying fruit in autumn.—*DAVID THOMSON, Treatise on the Culture of the Pine Apple.*

PHOSPHO GUANO A PECULIARITY.

SIR,—Having been for a long time in the habit of using phospho guano for general, and, in juxtaposition with other artificials, for experimental purposes, I have observed several peculiarities in connexion with its use, one of which I herewith seek to describe for the consideration of others, as well as in seeking to be further enlightened myself.

Last year I used it as usual, chiefly as a *stimulant*, applied to the growth of a great variety of horticultural and some ordinary agricultural crops, when an accidental circumstance led to my discovering the following characteristic: shall I call it a peculiarity?

A small portion in the bottom of a bag remained unused, and left neglected on a hedge-bank, until it had become quite wet—in fact, like mortar—by the action of the autumn and early winter rains. In that state it remained until the frosts and snows set in, and although fully exposed to the rigour of the former, it never became hard nor frozen, when the hitherto soft ground beside it had become so hard as to be with difficulty broken up by a pick or a crowbar. I left it untouched until the dry weather of spring, it being still soft and damp. I wished then to use it; but to render it friable, or easy of distribution, I knew not, except by artificially drying it by fire-heat. This I feared doing, lest that in doing so I might liberate and expel its volatile ingredients, which, when valuable, I wished not to lose. So I had it mixed with dry earth and pulverized as best I could, applying the compost, if I may so call it, in proportion of the phospho of 1½ lb. per statute perch, on which I had early York cabbages and cauliflower plants transplanted, and the luxuriance of both now agreeably surprises me. Another, as to me appears, remarkable peculiarity in this manure was this—last August, when sowing cabbage seed, I used the phospho, as a stimulant, at the rate of 1 lb. per statute perch, or at the rate of 1 cwt. 1 qr. 20 lb. per acre. Two crops grew most luxuriantly, a considerable number of which I had transplanted out in shallow trenches on newly-trenched ground late in November, I feared so late as to be unable to bear a severe winter, without contemplating the great severity of that we have passed through. To my agreeable surprise, the plants grow on most luxuriantly, never suffering in the slightest degree from the hard frosts, killing some of the hardiest, long-established cabbages in the same garden, as well as the tender, luxurious broccolis.

Now, what I wish to ask you and your scientific as well as practical contributors is, (1) Have you or they experienced any such results from the application of this or any other artificial manure? and (2), If such discovery has been discerned, to what ingredient in the manure itself may be

justly attributed such results? I am the more anxious to see this and such subjects discussed, not alone because of the information I would hope personally to gain by it, but with the view of dispelling some lingering popular prejudices still extant amongst some excellent practical men, who believe, and perhaps not without just cause, that plants of various classes, particularly of the Brassica tribe, when sown in early, or, worse still, in late autumn, and stimulated to luxuriance by other rich putrescent manures, are rarely capable of withstanding even the frosts of ordinary winters, less intense than were those of the past. Another question I would willingly ask, assuming that my crude ideas of the power of phospho guano to resist the effects of frosts, whether alone or in its influence on luxuriant plants to be correct, but which I would not willingly bind myself to without further proofs, might not its application to the roots of other plants early in autumn have the effect; if such was the case in the cabbage plants with me, to ward off the injurious effects of frosts on half-hardy, indeed I might say hardy, as usually considered, plants, such as were withered, if not killed outright, by the frosts of last winter and early spring?

Whatever my notions of this theory may be, I fancy the matter is at least worthy of investigation, and hence the apology, if such needs be, for my having trespassed to such a length on your space by my prosy ventilation of this matter.

May 22nd, 1867.

EDWARD CARROLL.

[As our esteemed correspondent asks for our opinion, we venture to give it, with no little diffidence, as we should in the first instance prefer hearing, as he desires, what our "scientific and practical contributors" have to say. That phospho guano wonderfully stimulates the growth of plants, whether applied in the garden or on the farm, there is no doubt, but that it or any other manurial agent could give them any peculiar frost-resisting power, except by rendering them more vigorous and healthy, we would be slow to admit. It is with plants as with men: the weakly and blanched will suffer from the influence of cold, when the vigorous and healthy will but enjoy it. We would rather look for a solution with regard to the immunity from injury of our friend's plants in the direction of his shallow trenches, and transplanting so very late in November. It is a well-established fact that recently transplanted roses, shrubs, &c., resist frost, while their established fellows beside them are killed. Why they do, no one knows better than our correspondent.—Ed. *Irish Farmers' Gazette*.]

Calendar.

WORK FOR WEEK COMMENCING JULY 13.

Kitchen Garden and Frame Ground.

CELERY.—The early crops to be earthed up as soon as the plants have attained a good size. If the ground is dry, give a heavy soaking of water the day before intending to mould them, and be careful that the soil is nearly dry, or at most only moderately moist, when the moulding is to be done.

Sow cabbage, green curled endive, lettuce, round spinach.

WINTER GREENS to be got out in plenty now, as peas, potatoes, and other crops are taken off. Collards, Brussels sprouts, and other quick-growing subjects that will mostly be used before Christmas, to be planted in manured ground; but those to stand till next spring, to furnish sprouts, not to be manured, as it renders them less able to withstand severe frosts. Continue to plant broccoli, Brussels sprouts, Scotch kale, and everything else of the kind from the seed-beds.

LETUCES FOR WINTER AND SPRING.—To have these in perfection during autumn, and from the middle of April to the end of May, sow from the 20th of July to the 10th of August, the full batch to be sown on the 25th or 26th of July. The best sorts to sow now are Hammersmith, Brown Silician, and Brown Dutch. These are the hardiest, and make capital saladings, and they do not need so rich a soil as the crisper kinds. In order to be very distinct, we should advise a sowing in a bed of fine rich soil, on the 20th of July, of true Bath Cos, which will supply good lettuces in October and November, and the smallest plants left will stand the winter. On the same day sow also, on a bed which was manured for the last crop, Brown Silician and Hammersmith. In the course of a fortnight make up a piece of extra rich soil elevated a foot above the level, and prick out the strongest plants of Bath Cos upon it, a foot apart every way, and keep them shaded and watered till they make a start, when remove all shading, and encourage them to grow with the help of liquid manure. If old frames are plentiful, make up a few reserve beds in them above the general level of the ground, and into these beds plant the weakest plants from the seed-bed, six inches apart. These frames will serve a twofold purpose. As soon as the plants are strong, remove every other one to a sloping bed under a warm wall, where shade and water, and let the others remain. The strongest plants will come into use during October, when we shall suppose the whole batch will be consumed. Those under the wall will succeed them; and if a smart frost should occur early in November, they may escape it through being high and dry; and if frost and wet destroy them altogether, the reserve stock in the frames will keep up the supply till Christmas, as any covering that will exclude frost and wet will suffice to protect them; and if they are kept in darkness two or three days together they will take no harm. In a mild season this plan will carry the supply—supposing the breadth sown to be sufficient—far into January; and it must be remembered that lettuces are always esteemed, and are as elegant on the table as they are refreshing to the palate. On the 25th of July, and again about the 10th of August, sow Hammersmith, Brown Silician, and Brown Dutch. These are all hardy kinds, and it is safer to sow a pinch of each than three times the quantity of any one, as if the winter should be severe there is a better chance of saving a few for spring use. On a good holding loam, without recent manure, if the beds are raised a trifle above the level, there will be a reasonable chance of these surviving the winter, and proving eminently serviceable for spring saladings. At the final planting they should be ten inches apart every way, and instead of hastening growth by liquid manure, they should have only just so much help after planting as will enable them to take root safely. Keep the ground clear of weeds, but use the hoe as little as possible, so that the surface may become hard and firm. It must be remembered that winter and spring lettuces are valuable, and when grown for market will always pay for glass. If a supply during winter and early spring is a matter of

some importance, all the spare frames and lights should be got ready at the end of October, filled with light sandy earth, the plants taken up carefully with good balls, and planted nine inches apart in these protective beds. Water them in, keep the lights off as long as possible, and when the plants in the frames must be consumed at last, tie a few every week to blanch, and keep them dry during severe weather, and they will pay for the care and the space they have had. Now that orchard-houses and ground vineries are in use almost everywhere, there may be made to pay their cost in keeping up a stock of saladings for winter. Grow the plants in open beds, and at the end of October or early in November transplant them carefully and keep them under glass, moderately dry and with as much air as possible, according to the state of the weather.

Flower Garden.

PROPAGATING PHLOXES AND PENTSTEMONS.—The only satisfactory way is to take cuttings, and get them rooted with as little aid from heat as possible. They may be multiplied in autumn and spring. The usual practice is to propagate pentstemons in autumn and phloxes in spring, but these last may be done in autumn with the others, if young shoots can be got from the base. If the season is a dry one, however, very few can be obtained, but in spring phloxes throw up shoots from the root freely, and if these are taken off when a few inches long, and potted round the sides of pots, and placed in a gentle heat, they soon make roots, and must then be potted singly. Pentstemons generally produce plenty of nice shoots at the base in autumn, and if these are potted, several together in a pot, and put in frames, they may remain till spring, and be planted out direct from the cutting pots to the places where they are to bloom. If the stock runs short, all the plants may be topped in spring, and will root quickly in a gentle heat. When it is intended to propagate largely, it is best to take up all the old stools, and pot them in large pots, and keep them in frames. By this means a large crop of cuttings may be obtained early in spring, and they may be multiplied *ad infinitum*. The plants produced in this way do not, of course, attain to any great size, but they produce fine flowers, and those who grow for exhibition should follow the practice of propagating annually. It would be well to mark while the plants are in flower all those it is intended to propagate, as the time for taking cuttings of pentstemons is near at hand.

AGANTHUS to have abundance of water while throwing up flower-spikes, and until the bloom is over; then to be shaken out and parted, and the strongest crowns selected for next year's bloom. Pot these singly in small pots, removing with a sharp knife any of the straggling roots that cannot be got into the pots. The soil should be sandy loam, rotten dung, and peat, equal quantities. Shut them up, and re-shift as soon as the pots are full of roots. The small off-sets and the fleshy roots may be used for increase of stock. Plant in shallow pans of sandy peat, and place in a gentle bottom-heat for a fortnight; then separate them, and pot singly in sixties.

TALL-GROWING BEDDERS need a little care now to protect them from high winds. A very effectual and expeditious method is to insert strong stakes, and run a few lengths of stout tarred string amongst them, so as to form a support to the back and front of every row. Small forked branches will serve the same purpose where the plants are not sufficiently regular to be supported with string.

CHRYSANTHEMUMS in the open ground to be topped again, and the soil between them lightly pricked over with a small fork, and some quite rotten dung worked in. It will be found that they always root near the surface, and a dressing of dung will greatly help them, and save the labour of watering.

CINERARIAS coming up in seed-pans to be pricked out as soon as large enough to lift, and have separate thumb-pots, with light rich compost, and be put in a frame to grow on. By securing a vigorous growth from the first they will be less troubled with fly, and make fine specimens. Those who have not sown seed yet must do so at once, or it will be too late.

Fruit Garden and Orchard House.

PLUM TREES in orchard-houses are in many cases covered with fly. If this is not checked, the trees will be barren next season. Make a strong infusion of tobacco, and at the same time dissolve a little glue; mix them together, and add water in a large tub, and into the mixture dip the trees. Any that are too large to be dipped must be laid on their sides and well syringed. Those dipped must also be syringed the next day. If the labour can be found, it will be more effectual to paint with a soft brush every leaf, under and upper side, with a mixture of one pound of dissolved glue, one pound of tobacco, and four gallons of water. The leaves will appear after the operation as if varnished, but not a leaf will fall, and it will make an end of the vermin. After a few days syringe them freely.

FIGS producing a second crop to be fed liberally, and have a top-dressing of quite rotten dung. The top growth must be pinched back.

Greenhouse and Conservatory.

FUCHSIAS must be syringed twice a day, and have moderate shade. Fine plants in comparatively small pots will be greatly benefited with weak liquid manure every three or four days. The stock must be propagated now in quantity for next year's supply. The smallest cuttings make the best plants, and there is no need to cut to a joint. A mild bottom-heat will hasten the formation of roots, but it is not needful, as if shut up in a cold frame and kept shaded and regularly sprinkled they will be well rooted in a fortnight. It is a saving of time in the end to put all cuttings singly in pots at this time of year, as they can be allowed to fill the first pots with roots, so as to grow strong from their first start. In preparing pots for the cuttings, use smallest sixties or thumbs; put a mixture of turf and old dung over the crocks, and fill up with half sand and half leaf, in which the cuttings will root as quickly as in sand alone at this season, and have something to live upon while filling the pots with roots. This is the best method for amateurs who are much away from home, as the single cuttings require less care than when dibbled into sand only in shallow pans.

HARD-WOODED PLANTS requiring a shift this season must have it at once, or the time will go by for them to derive full benefit from the operation. The most important matter of all is to secure good drainage, and to use the compost in as rough a state as possible consistent with the size and nature of the plant. Whenever the cultivator is in doubt about the best soil for any hard-wooded plant, he will be pretty safe in using half peat and half loam, both in a turfy and sweet condition, the more elastic the better.

PELARGONIUMS, as they go out of bloom, to be cut down, and placed in a warm, sheltered, and rather shady place for a week, then to be put in the full sun, and kept rather dry at the root, with occasional sprinklings of the stems and leaves till they break, and then to be repotted back into small pots with sound lumpy turf to make their new roots in.

Stove and Orchid House.

ORCHIDS.—The general collection may be kept in perfect health now without fire-heat by shutting up early, and sprinkling the floor of the house to cause a humid atmosphere. Do not shade over-much—generally from ten to three will be quite sufficient from this time till shading is dispensed with altogether. Small specimens of Stanhopeas should be now shifted into large baskets, in which they can push their flowers downwards. The best material to fill the baskets with is chopped moss, and the tough felt-like fibre of good peat, with all the soil removed. The baskets should be shallow. After shifting, keep them well supplied with atmospheric moisture, but only moderately moist at the root. Specimens that do not require a shift are to be encouraged to grow as soon as they have done flowering, in order to assist the completion of their pseudo-bulbs, and then they must be reduced to a state of rest by gradually withholding water, or to have but little until they again begin to grow. All the Stanhopeas will grow in either house.

Forcing Pit.

MELONS swelling fruit to have plenty of weak manure-water; those ripening their fruit to be kept tolerably dry, but if kept too dry will get infested with red spider, so endeavour to keep them in good health on the smallest possible supplies, and give plenty of air. Those that have borne good crops may be cut back, and set to work again with the help of linings to the beds. Keep these rather close after pruning in, and frequently sprinkle the sides of the frames and the surface of the bed, and give only moderate waterings at the root. Never allow water to fall on the main stems. If the plants cut in appear rather poor, let them break moderately, and then remove a portion of the soil from one side of the roots, and replace with fresh turfy loam. When the roots have run into the new stuff, do the same on the other side, and they will swell a second crop admirably. This is a first-rate season for melons, and if they have not a good flavour and their proper colour, it is the fault of the grower only.

PINES.—The bottom-heat must be kept up, and there must be plenty of room between the plants for a free circulation of air. Maintain a moderate humidity among all advancing crops and young stock, and in giving air guard against drying winds and draughts by keeping one side close while the other is open. Where the fruit is swelling nicely, sprinkle the surface of the paths and soil frequently; but where the fruit is changing colour, discontinue the sprinkling, and give only just enough moisture to keep the plants in health. After cutting fruit, earth up the stools, and give a brisk bottom-heat and plenty of moisture. Beds in which pines are plunged must be kept constantly moist, as the heat will not rise through any dry material.

VINES now require air night and day from the time the grapes are gathered, unless they are in poor condition, and the wood very green. If so, shut up early, and in another eight or ten days the wood will be getting hard, and then there may be air on night and day. Grapes ripening not to be syringed, but to have a moderately moist atmosphere and plenty of air.

PEACHES AND NECTARINES must be fully exposed to the atmosphere as soon as the fruit is gathered. Where the fruit is still banging, give plenty of air, and every morning a light skiff with the syringe over the leaves. Stop the strongest shoots a few at a time, to swell the ripe buds. Wall-trees are generally loaded with superfluous wood, through the prevalence of a delusion in favour of plenty to choose from at the winter pruning. Choose now, and remove all that will not be wanted, and what is left will ripen properly.

PREPARATIONS FOR WINTER FORCING must commence in good time. Look after strawberries, potted trees, &c., &c., to ensure having them in condition for forcing, when required.

NOTES ON POULTRY KEEPING.

"The countryman's farm or habitation," wrote Mortimer, "cannot be said to be completely stored or stocked without fowl as well as beast, which yield a considerable advantage by their eggs, brood, body, and feathers. Any poor cottager that lives by the highway-side may keep them, they being able to shift for themselves the greatest part of the year by their feeding on insects, corn, or anything almost that is edible by any other sort of animal; and therefore they are kept to great advantage at barn-doors, or other places where corn or straw is scattered. As for cocks and hens, I shall not enter into a description of the several sorts of them, only advise you to choose those that are the best breeders and the best layers; but no sort will be good for either if they be kept too fat. The best age to set a hen for chickens is from two years old to five, and the best month to set them is February, though any month between that and Michaelmas is good. A hen sits twenty days, whereas geese, ducks, and turkeys sit thirty. Observe to let them have constantly meat and drink near them while they sit, that they may not straggle from their eggs and chill them. One cock will serve ten hens. If fowls are fed with buck or French wheat, or with hemp-seed, they say they will lay more eggs than ordinary; and buckwheat, either whole or ground, and made into paste, is a grain that will fatten fowls or hogs very speedily, but the common food to fatten them with is barley-meal wet with milk or water; but wheat-flour is better." So amusingly and shrewdly wrote one a hundred and fifty years ago, who would be eminent nowadays as an agriculturist were he alive. Still information so indefinite will hardly suit the modern amateur. Then must our "prentice hand" essay the subject.

For myself, I have a partiality for the elegant *game fowl*, which, moreover, have the recommendation that they feed a good deal on grass-seeds; leading a gipsy life more than any other kind; encamping in the open; concealing their nests, as the landrail, &c. The black *Spanish* have a charm with many, and certainly they deserve credit, if for nothing else, for the extraordinary whiteness of their immense eggs, being in wonderful contrast, whether intended or not, to the glossy black of their plumage. To the *Dorking* and the *Cochin-China* I have the same objection that I have to a musty gossip. They may be a very good sort of animal—profoundly maternal—a useful, hospitable, routine running class—but, as I am penning

my own feelings, I must confess my aversion to the sort. A serviceable cross for the table is bred between the *Game* and *Dorking*, of which I saw some magnificent specimens in the straw-yard of Mr. Booth, of Warlaby, about the only cross-bred stock he has about his interesting place. A *bantam* or two well chosen, black or golden laced, give a finish to the stable-yard—a style and stamp as the rim of plaited straw along the hunters' stalls. Curious, if correctly stated, is the plan mentioned by Richardson, whereby that ingenious nation the French get extra duty out of their hens in the way of eggs. We are informed that at an early period after hatching they band over the young brood to the care of a fattening capon, whose services they enlist as nurse. The way 'tis done is this: The last-named unfortunate they catch and divest of his nethermost feathers; the denuded part they whip with a rod of nettles, and then turn him, smarting and affrighted, into a darkened room, into which they introduce also a brood of young chickens, not less than he conternated at being torn from their mamma. He looks, however, kindred, and they immediately make for him cowering in the corner, and, from instinct, crowd for refuge under his wings. By the close subsidence of the downy little fellows, the poor bird is so eased of his torture, that out of very gratitude he comes to behave towards them as the parental hen would. By the time his affliction is abated there is a sympathy established between them, and he is loath to take a lively interest in his protégés, and performs for them with a will all the numberless little offices, such as scratching for grain and grubs, chuckling to them to come and share, &c., which he remembers to have been done for himself in infancy.

As for *geese*, I abhor them; their cackling is abominable; their grease alone to be valued, as a first-rate specific for many purposes upon the farm, such as rubbing a bard udder, &c. Their meat is indigestible, and endurable only for the sweet apple slop's sake in which it is the mode to envelop each morsel. During life, besides hissing at your horse's heels, and chasing you their lord and owner, every three of a flock will consume as much pasture as a sheep, besides spoiling with their dirt and feathers I don't know bow much more, not to mention the green, muddy, unwholesome slush to which they rapidly reduce your stable-pool. But if you have a fancy for the like, most gentle reader—and I suppose he may be reckoned a goose who has not—then, for the best sorts to begin with, you must consult Mr. Bailly, or Mr. Fowler, or some equally distinguished (if there be any) presiding genius of the clan. However, I can tell you that the sooner the better they commence laying in the spring, as they may then have a second brood. They will inform you that they are laying by carrying straw about in their bills, as pigs do before rain, or when about to farrow. At once, then, batch their nest over for them with a tent of straw. They lay twelve to sixteen eggs. They sit usually thirty days, but if the weather be fine and warm, you must not be surprised to find the young ones introduced a few days sooner. For a "*green goose*," you must take them a month old and stuff them, keeping a little rack of fine hay beside them, which they will nibble at, and by the termination of the second month they will be ready for the table. Our plan is rather to go to an old woman who has hatched them under her bed, and buy a brood just advanced to jacket and trousers about stubble-time, when they will at once take to gormandizing kindly on the sheaves' debris, and will be ready to kill by the time the fields are picked. Carrots cut small, or sliced swedes, alone will fatten them, or barley-meal and milk; but best, 'tis said, of all, malt mixed with beer.

"But in fattening of all water-fowl," writes our sagacious friend, "you may observe that they usually sit with their bills on their rumps, where they suck out most of their moisture and fatness at a small bunch of feathers, which you shall find standing upright on their rumps, and always moist—with which they trim their feathers, which makes them oily and slippery more than other fowls' feathers are, that the water may slip off them—which, if cut away close, will make them fat in less time, and with less meat, than otherwise." "Tell that to the marines!" I hear an impatient comment. Well, I know but what I read, and I have presented you on purpose with the original text. With this weeping spring, then, and its incumbent plume, it may be as well for you to make yourself acquainted, if you be given to the nurture of geese. It is at least an ingenious adaptation of native produce that is surely worth trying. Midsummer, he tells us further, is a hard time for the constitution of the goose. Can this be, I wonder, that little boys are then at home from school for the holidays? And now, as I suppose you don't much care to go in for shearing and plucking geese, or half-roasting them before a slow fire, for the sake of pâtés de foie gras, or, indeed, for the perpetration of any such kindred barbarity, we will, by your leave, say here, Good night to Marmion, and proceed upon the even tenor of our way.

But the turkey's "my darling, my darling, my darling!" White, copper-brown, or barred, they are a gentle, profitable fowl, not excluding the grand Turk himself, who slices magnificently at Christmas-time, if well foddered in life, and in death well carved. But the hen—so sweetly waning in the long-tongued bombast of her Cleon-like spouse—if you seek to watch her to her nest, she walks so leisurely, with an air so ladylike and well-bred, so gracefully nonchalante, just pecking indifferently at the grass-seeds as she passes; no vulgar cunning about her, no sly bucolic tricks; one is almost ashamed to sneak along behind the fence and dog her to the retired spot, where she glides up noiselessly into the hedge, and, picking off the dry leaves with which she had concealed them from the crow, resumes her solitary guard in the far-off fence upon the fine, delicious, delicate, pink-spotted eggs, so frequently, alas!—unless removed to quarters nearer home—to disappear by the knavery of Reynard.

When hatched, if you find the wee ones pining, their dear little wings trailing helplessly along the ground, and their whole air depressed, then whip them up, and having conveyed them within the bright kitchen, administer to each a small pill of ground pepper, bread, and port wine—some give a peppercorn in its entirety alone—and let it warm its feet in a spoonful of good whisky (they are so tenderly exotic). Next wrap them in some wool in a basket, and shortly they will be all right. This was taught me by a clever lady, who, during a kind of duty exile with her husband, who had charge of the dispensary attached to Lord Breadalbane's quarries in one of the Western Isles, had bent her gifted mind to the collection and combination, for culinary and household purposes, of the native resources of the island, after a most Crusoe-like fashion, which was intensely delightful to my schoolboy feelings; flesh, fish, herbs, all treasures of the deep, the very flowers on the hill, all came to hand convenient for the manufacture of pickles, wine, preserves, or dyeing material, until, to one's lobbledeloy vision and appetite, her sanctum appeared an absolute Fortnum and Mason's dépôt.

For ducks, I suppose, the white Aylesbury and the brown Rouen are the

most profitable to keep. The black East Indian (whose polished plumage, heaving as they bask asleep in the sunlight, glistens with a wot-like, shoeny look, that seems the very idea of the Pindarie *bygdv vōtov*) I believe some find us paying as ornamental. Our own weakness (to which I recommend not the reader to lean) is for the native wild duck. A nest or two of eggs are easily procured from the nearest fen and hatched under hens. When the young ones appear, mind and keep them under cover with their foster-mother for some days. When their feathers are sufficiently grown, catch and pinion one wing—that is, with a sharp knife cut off the end joint. Their offspring will be sufficiently domesticated for you to forego this operation. I love to watch them, about nightfall, wing their way round and round the homestead, their pinions whistling as they pass overhead to settle down again quietly as ever, as though nothing had happened, upon the pool, drinking up the water so enjoyingly, and coming at call to feed even from my hand.

They are small when dressed for the table, but their flesh is peculiarly delicious. Three-parts grown ducks are useful to turn into gardens or a turnip-field, where they will do good service by swallowing up the destructive slug and caterpillar hordes. Their nests of down they make under a heap of thorns, with which I have a high rocky bank beside the pool covered, or in a hedge not far away. They cover them so carefully with dry leaves when they leave them, that it requires a keen eye and some practice to detect them. It is best done—though that consumes time—by watching the duck return. While sitting, her bright eye will discover her, when you would not have noticed her plumage amidst the brown herbage—so much her own hue—wherein she as ensconced herself. Take the eggs when they have reached the number of twelve or fourteen, and set them under a hen. The duck will make another nest shortly. Under any circumstances she is a bad mother, leading her little ones at once to the water, which, oddly enough, is about the worst that could befall a young wild duck domesticated; the hatch getting rapidly thinned, and perishing oftentimes altogether from the combined assault of oramp, pike, rats, and an occasional, but invariably most voracious, crow, whose young, clamouring on their platform of cross-twigs in some neighbouring elm (they are very faithful to the same spot year after year if not got rid of), it is your first duty to destroy, if you have any respect for your poultry's welfare. An egg prepared by the chemist with a taste of strychnine, set out upon a wall in a field (where it must be watched) will infallibly attract and instantaneously tumble over the old birds. Mind you do this before you destroy the nest, or they will but remove a short way, and give you the same trouble again.

Let me conclude with a few practical hints, which I have bought by sad experience.

In the first place, beware of strewing the spar of lead mines as gravel upon your walks, for fowls will occasionally find their way where they should not, and will pick it up for gizzard service. It lacerates the intestine, they pine gradually away, and die.

Old fowls, as pigeons, may be used up, and found at least as palatable as the brood-hen of Wolf's Crag, if you administer a strong dose of vinegar to them a little before they are delivered to the headsmen.

And, young housekeeper, know that if you would delight your grand-mamma's heart with a devilled chicken leg of superlative excellence, let it be out of the raw fowl to be dressed, and not be the remnant of yesterday's dinner. It is the second cooking that makes them obstinate food.

Keep your hen-house most particularly clean, and often whitewashed. The nests should be made of dry heather (*Erica tetralix*)—the badge, by the way, worn in the bonnet of the Macdonald—and small branches of hawthorn, covered which white lichen. (*Richardson*.) You will so cheaply save your sitting hens much torture: the effect of the frayed hoary bark produces a large amount of powder, which is as drops of stingo to the plaguy parasite, whose name is legion, that is ensconced within the feathers of the unhappy fowl, attempting to relieve themselves of which you see hens roll so in a dust-hole when they can. If by any accident—and accidents will happen in the best regulated families—a fowl or a duck should break its leg, having washed the wound and set the bone, a bit of elder twig, hollowed of its pith, and split, affords a capital pair of splints. For further information on this head consult "Ferguson's Practical Surgery," and forgive me the bother this reading has cost you.—Rev. W. HOLT BEEVER, in "Notes on Fields and Cattle."

ABOUT WEATHER PROPHECY.

It is with a view of implanting in the mind of the little world to whom the weather is of importance, and that in the very direct way of bearing upon their very lives, that I am induced again to "take up my pen and write these few lines to you."

Some time ago I wrote at length a theory of the weather, which was part of that inculcated and accepted by the late Admiral Fitzroy—that part which more especially bears upon our situation in this temperate but uncertain climate. Since that time there have appeared two modes of foretelling the weather, upon which I shall speak, but to carry out and apply the former theory will be my especial object.

Now, I must premise that the reader is aware of such a thing as this—to prophesy a particular sort of weather, and, never minding what follows, to select such propitious moments as happen to coincide with the prediction, and then say, "Ah, I told you it would be so."

Now this is all very well, and may quite satisfy the "ruck" of people, but we must not let it satisfy us. It is in consequence of this easy and natural perversion of our reason that you may find so many of the old moon people still; and this leads at once to the point.

I often wonder what people would pick up for a cause of weather changes if the earth had happened *not to have had a moon*; what then of all the sapient observations, and mysterious shakes of the head, concerning the change of the weather most likely to follow on the next new moon? Why, half the happiness of life would be gone at once. So now, perhaps, the reader is beginning to find that I don't quite "see" the moon theory. But we will speak of the other—a military officer's theory I think it was. Well, this was a moon theory too, and one which to me seemed tolerably reasonable, inasmuch that I took the trouble of looking over my register for the last twelve months to see how it agreed. By this theory we were to take off the fourth, fifth, and sixth days of the moon, and, dividing the rest of the time into three periods, judge of them by these indicating days. The thing seemed so far reasonable that you might imagine it to take three or four days to let the change of the moon take proper effect.

The result of the examination was as follows:—Giving a mark to each third part of a lunation, I find to fourteen marks in favour of the theory

there are seventeen against it, and six doubtful. Now, the only argument I can see for the moon people to take up would be that of an impostor who said he was a shipwrecked sailor, and when he encountered an old salt who asked him which was the port side of a ship, he looked up, then down, waited a while, and then faintly muttered, "They don't call it that in America." So it may be that in America, or perhaps in some other favoured spot, the weather is very obedient, and does as the moon tells it; but, black for this ill-fated island! the weather here is evidently (as was shown in a pithy little article which appeared in the papers a short time since) loyal to Her Gracious Majesty, and does not care a bit about the moon; at any rate, concerning the latter part, I believe that all facts are so dead against the theories of the moon's influence, that if any man, knowing all this, still believes, or pretends to believe in them, I should next expect him to plant his cabbages roots upwards, and do other similar diversions. Now, mind, it is only to save time that I have missed the other theory, set down by Sir John Herschel as "based on scientific principles." You see, if it is all nonsense, then all the worse for Sir John Herschel, and all that have had to do in the making of it, for the sun, rain, and wind do not respect persons.

I will now as quickly as possible proceed to the other parts, and at the commencement I wish to say, Let no one think the thing intricate or difficult, for if he once gets at the principle I know it will pay for the trouble; I say this because I know many people go groping about with not a tittle of that knowledge of things which they ought to have, just because they have, thinking it troublesome to get it, got bold of a habit of saying in a supercilious way, "I don't understand it; I don't pretend to know anything about it." The intelligent reader will not fail to perceive that this is very foolish; so now to business.

The first lesson was to see that the polar and equatorial currents were constant things, and somewhere or other came into collision, but now we will see the meaning of their direction more clearly. Now the two currents are naturally north and south, but the rotation of the earth causes the south current to turn to the south-west, while the same cause makes the north current turn north-east, the one overleaping the motion of the earth and the other lagging behind it. So, if a north wind becomes diverted until it is due east, it is a sign it was a very weak one; and if a south current becomes turned due west, it is a sign it also is very weak. But as these are more north or south so are they stronger or more persistent; remember this.

Second: If the wind is generally easterly, it is, as I showed in the former paper, a sign that the winds are convex towards the west, and that therefore the south wind is at the time stronger than the north; so, too, if the wind is generally westerly, it is a sign that the two winds are convex towards the east, and therefore the north wind is stronger than the south.

It is as a consequence of this simple and easy theory that the sailor says: If the wind goes with the sun, all will be well; but if it goes against it, it will be had weather; because these are the only natural true changes of the wind, and if it is diverted from them it is a sign of a great disturbance somewhere.

Thirdly: I showed that the north wind always kept to the ground, while the south wind always kept up high by preference. From this at once you see that, if a north wind obtains on the ground and also right into the upper currents of the air, it is very bad; it is both strong because north, and powerful because deep. Such is the case now, June 28th. Also, if a south wind is very deep, and near south at all levels down to the ground, it is a good sign, in the same way. Now remember all these things, and we will continue our inferences from them.

We never want telling what the weather is. What we want is to know the time and nature of the next changes. Now this varies according to the time of the year, and, secondarily, according to the kind of season; yet, generally speaking, these two currents are very plainly shown during autumn, winter, and spring. During the summer they become more broken up, and it is at this period that prophecy is more difficult.

Beginning with spring, then, and taking this last spring as an instance: the winter broke up on January 22nd, the wind moving bodily round from E. (where it had been for two days) to S.W., but it was weak, and therefore fluctuated. On the 29th a strong S.W. wind came to its assistance. On February 3rd began a prodigious fall of the barometer, and on the night of the 5th a furious gale from W. The wind then weakened, and fluctuated W. to E., and S.E., E., S., and W. from 20th to 26th (indicating a convexity eastward and a stronger N. wind). The wind was then E. until March 9th, and varied between N.E. and S.E. until the 22nd. Thus the west wind was truly prophetic. A new S.W. wind came then, and was strengthened on the 24th and 27th. It then softened, and kept W. from whence on April 8th there was a strong gale. Until the 24th the warm wind prevailed, varying from N.W. to S.W.; but then came a singular change—one which I believe very seldom happens. The warm wind was met so exactly in the face by the cold wind, neither of them being very strong, that until May 11th was a time of almost perfect calm. The weather was fine, as the currents were not of a mixed kind, and so we had that excessively hot weather so much wondered at. Calm weather being always favourable to heat, because the hot air near the ground does not get the cold air above forced into it by the wind, or rather when there is no motion there is no mixing.

Any one observing would feel the danger of this state of things, and could be prepared for it—at least, I was myself. The cold wind came again on the 12th, no doubt accelerated by the collapse which followed on the thunderstorms of the 10th and 11th. On the 18th the cold wind seemed to slacken, and promise a release; but early on the morning of the 21st we about London were greeted with a bitter cold wind, as usual ushered in by a wretched rainy day. Then came those killing frosts which did such havoc amongst the young planted bedding stuff. On the 24th it went E.; on the 25th it was S. This easterly change was very light, showing that there was scarcely any convexity westward, and that, therefore, the weather was not yet to be trusted.

A moderate south wind then came up, lasting till June 13th, latterly inclining far too much westward, and, although the weather was very hot at the time, I was much afraid. On the 14th came another N. wind, and with it those choice curiosities for which our English climate is, I should think, quite peculiar, namely, *midsummer frosts*. There were two at least, perhaps three; but my geranium petals being once nipped, would not show any more. Then until the 28th the wind was N., and getting more and more parching and dry. On the 29th it went southwards *by west*, or, as the sailors would say, "against the sun." Perhaps before this reaches the hands of the reader we shall have again seen the truth of this apt old saying. Like most summer disturbances, it has threatened more and more

until now. On the night of the 1st of July it looked very likely to produce something.

I think I have written enough; this I say in conclusion, that the more any one studies the subject in a rational way, the more encouragement he will find to go on.

I shall some day show what is the proper sphere of the barometer's indications, and also what a deal more is to be found without its aid, if you use your head, than with it if you do not.

A. DAWSON.

THE POTATO DISEASE.

Here in the west the potato disease has shown itself severely for the last fortnight past. All the early crops are already sadly affected amongst the tubers, and the later crops have received a severe check in their growth—indeed, to such an extent that many of the cottagers are pulling them up, and filling the ground with winter greens, as this is their only chance of turning their garden plots to a profitable account.

Having carefully noted the appearance of the potato disease for some years past, its early appearance this year has somewhat surprised me, because there has not been, as far as my own observation goes, those favourable conditions of the elements for its production which I have hitherto observed as the sure forerunner of its appearance amongst us; therefore I am more than ever perplexed to understand its origin, and less inclined to accept some of those opinions that have been advanced as pointing out the sure cause of the disease. My own opinion I have already made known in these pages; and although cause and effect may be opposite to each other in this case, the cause would not be so serious were the effect less disastrous.

J. C. CLARKE.

Replies to Queries.

Ditty and Son, Cottenham.—Your seedling verbenas are good, and if bedders in habit more than good, and valuable. No. 1 is a deep scarlet crimson flower, with small primrose eye, very stout and large pip, truss small. No. 2 a pleasing shade of rosy purple with gray eye, a stout pip of good size, truss small. No. 3 extra large pip of velvety substance, and a fair sized truss, colour indigo purple shading to plum, large primrose eye. No. 4 maroon crimson, large primrose eye. Having been grown in small pots accounts for the small size of the trusses; grow them again, and more liberally.

G. C. S.—Yours is the true *Viola cornuta*. There is a form of *V. calcarata* in cultivation under this name, but it is at once distinguishable by its long spur.

H. H.—Your strawberries have not come to hand to this date. Should they now arrive they will of course be past all condition for judging.

Novice will find at page 454 of last year's issue (October 6, 1866) directions for the profitable use of tan in the formation of hotbeds.

G. F., Gateshead.—We can have nothing to do with your purchase of peat. We are simply advisers, not agents. You had best take counsel of some respectable nurseryman of your own district.

J. C. Crussel.—We can give no opinion on *tropæolums* the size of a mouse's tail in thumb-pots with one flower each.

Verbenas for Exhibition.—W. S.—Lord Leigh, L'Avenir de Ballant, Perry's William Dean, Perry's Snowball, Annie, Perry's Delicata, La Grande Boule de Neige, Mrs. Elphinstone, Warrior, Antonia, Azorea superba, Perry's Gem.

Celery for Exhibition.—W. S.—It all depends upon the system of judging which are the two best for exhibition. If size is to be the most important quality, Manchester Red and Cole's Crystal White are perhaps the best. But if beauty and flavour are to be considered, we should vote for Turner's Incomparable White and Hood's Imperial Red.

Lawn Mower on Rough Ground.—Old Subscriber.—We must decline to name which of the many good lawn mowers we should prefer for your particular work. We should be always in hot water, and deservedly so, if we were to recommend traders, and we never do so except there are peculiar circumstances to justify it. If the surface of your newly made lawn is so rough that the roller rattles in going over it, the scythe would be the best mower for the present; but if the roughness is in the nature of undulations, or such as we may call a wavy surface, a mowing machine may be used with perfect safety, and the cutters should be set as high as possible. It is best to mow while the grass is dry, no matter whose machine is employed, but any good machine will mow wet grass if it is not extravagantly long.

Peas.—A. B.—The peas that came up so well "as not a seed seemed to miss," but which afterwards turned yellow and perished, were probably in poor ground, and got burnt by sun-heat before they had time to make good roots. If you refer to page 338 of last year's volume (July 28, 1866), you will learn how peas are treated on the trial ground at Stoko Newington. And again, if you will read the weekly notes for kitchen garden work which appear under the head of "Calendar," you will be frequently advised on the subject. To grow peas well a trench should be opened for every row, eighteen inches deep and two feet wide. Plenty of good rotten manure should be spread along the trench, and be dug in and mixed with the soil. The earth taken out should then be returned, and the line put down for the drill. The drill must be drawn with the hoe, and should be full three inches deep. Along this drill the seed should be scattered regularly, sorts that are comparatively weak growers rather thick, but strong growing sorts two or three inches apart. Draw the earth over the seed, and leave all alone until the peas are pushing through the ground, and then dust them with the fine stuff from a heap of charred rubbish, or with wood-ashes, or with lime, and as soon as they are three or four inches high draw the earth to their stems, and put stakes to support them. The "Rose Book" is published by Messrs. Groombridge and Sons, 5, Paternoster Row; the price is 5s. The "Florist's Journal" has been for many years past discontinued. We do not remember any other letter of yours.

Asparagus Beds.—C. T., Aberpergwm.—When we recommend the application of manure to asparagus beds, we are dealing with asparagus beds generally, and not with any particular bed in any particular garden. If your asparagus grows strong enough already, and manure is not needed, all

you have to do is to save the manure for something else. From the description you send, we think you may very well dispense with the application of manure this season.

Vine.—G. W., Lea Bridge.—The egg-like excrescences on the growth of the vine are not at all uncommon. They do no harm, but their appearance is usually an indication that the vine requires more air and less moisture. This is one of the many ways in which plants speak to us in respect of their well-re and requirements.

Liliums in Devon.—Florida had best allow the offsets of *Lilium giganteum* to finish their growth in the ground, and then they may be taken up and re-planted, and probably amongst them may be found some bulbs that will flower next season. There is certainly no better method of growing this magnificent lily than in the open ground, especially in your Italian climate. *L. auratum* is hardy in Herefordshire, Middlesex, and Sussex, as we know by several instances. We may conclude, therefore, that it will be hardy in South Devon. The best soil for these lilies is tough fibrous peat. Do not on any account give them liquid manure, but you may give any quantity of pure water while they are in active growth. The gentleman to whom your note is addressed is an amateur cultivator. We have forwarded the letter, sincerely hoping it does not contain an order for plants.

Acacia.—Sibley.—The tree commonly known as the Acacia in English gardens is that known in books and botanic gardens as *Robinia pseudo-acacia*, a tree of majestic growth, light green pinnated leaves, and a half weeping habit. The flowers are produced abundantly in the month of May; those of the variety commonly planted are white, but there is a variety with red flowers. This is the celebrated "locust" tree, which Cobbett regarded as the best of all trees to plant for profit, but which has never acquired any degree of importance as a timber tree in this country, though for gate-posts and rustic furniture it is invaluable. It is a good tree to plant in a town garden, though it makes a litter beneath it all the summer long.

Vines doing badly.—Ben.—Your vines appear to be in a badly made border, and to have an excess of atmospheric moisture. You do not say what sort of border they are planted in; we should suppose it to be too wet, too fat, and perhaps too cold. The leaves have the appearance of having been grown in a close steaming atmosphere.

J. Chambers, Westerham.—Your plant is *Lycopodium inundatum*, a rather common plant in marshy places in the south of England. We do not answer queries of this kind privately.

Delta.—Your Maréchal Niel roses are on Manetti stocks, so you will know how to deal with them. No better way of learning the difference between Manetti and Maiden's Blush than to grow them both for a few years in some out of the way spot. The second of the two named will give you flowers well worth having.

Enquirer.—Any cheap alkali, such as soda or potash, or a few drops of hartshorn, will soften hard water.

Removing a Swarm of Bees.—H. B. makes the following inquiry: "Wishing to remove a swarm of bees about sixty miles by rail, I should be obliged for your opinion as to which is the best way to do it, as I cannot start before the middle of the day, when many of the bees are out. Should I stop the opening the night before with perforated zinc?" It is very unfortunate that the removal cannot take place after dusk; but as it must be done by day, the only safe course is to stop the opening by means of perforated zinc the night previous. This must be done *securely*. Before removal the hive must be firmly bound to the floor-board, and made so safe in every respect that there will be no chance of the bees escaping at any crevice. If the hive has been supered, it would be well to remove the super a day or two before the hive is taken away, and reduce the affair to the smallest possible compass. In the process of conveying it to its destination take care it is not subjected to any jar or shock, and on arrival place it at once where it is to remain, and do not remove the zinc from the opening until the evening, when it is nearly dark.

Correspondence.

PAMPAS GRASS AND ARUNDO CONSPICUA.—I shall be glad if you or some of your readers can inform me what are the natural conditions under which Pampas Grass and the Arundo conspicua flourish—whether these plants are, in their native haunts, growing all the year or dormant for a time, and whether they are found on the banks of streams or in the open plain. A year or two back I had a number of seedlings of Pampas Grass; some were put out in a border, and some were put in pots and left standing on the border in the open. To my surprise, the plants in pots grew much faster than those in the border, though no care was taken of them beyond an occasional watering. This could only be from the pots getting hot in the sun. I was led to examine the roots of a large plant which I had in a border with a southern slope. I found that there were no roots extending behind where the earth was damp, and shaded by the grass and by surrounding shrubs, but abundance of roots in front on the exposed and therefore comparatively dry part of the bed. This satisfied me that in this climate additional heat was much more wanted than additional moisture.

I have a plant of Arundo conspicua on the same border sloping south. It was only planted this spring, but at present it does not seem likely to flourish as well as the Pampas Grass.

It may be useful to some of your readers to know that the latter plant appears to flourish almost as well in a suburban garden as in one where the purest air is present.

W. R. WILLS.

Edgbaston, July 6th, 1867.

AMERICAN CEREALS.—Wheat was first sown in the North American colonies in 1692, on the Elizabeth Islands in Massachusetts, by Gosnold, at the time he explored that coast. That has been just 252 years ago, and since that time so great has been the increase of this cereal, that in the year 1849, according to the census of 1850, the product amounted to 100,503,800 bushels. Up to 1610, and perhaps later, England supplied the colonies with the greater part of their breadstuffs. How changed is it now! All Europe is looking to us for bread. The bread sent to the colonies in 1610 was not cast upon the waters never more to return. Two hundred and forty years afterwards it rolls back in a continuous stream, to gladden the hearts of half famished millions in England, France, and Belgium. The descendants of man originally lashed and scourged from their shores, and forced to make their future habitations beneath the uninviting sky—more humane than the taskmasters of their fathers—are now striving to return good for what was considered an evil, by supplying them with bread.—*American Paper.*

The Gardener's Magazine.

SATURDAY, JULY 20, 1867.

EXHIBITIONS OF ROSES WILL GRADUALLY DECLINE from their present popularity unless invigorated by the introduction of features tending to render them less exclusive and restricted in their purpose. We have not the least fear for the Queen of Flowers, that her votaries will become weak in their attachment or treacherous in their zeal, for as long as floriculture shall have any claim on the thoughts and feelings of mankind the Rose will have its admirers and pains-taking cultivators, and self-sacrificing exhibitors, anxious to influence by their example and their works the general tone of public taste. But a rose show depends for its success on the approbation and support of the general public. The select circle of rosarians are insufficient in numbers to constitute a public large enough for any exhibition held in a place of general resort, such as the Crystal Palace, Sydenham, or the Town Hall, Birmingham. And if they were, it would be very undesirable for them to keep the exhibition to themselves; one of its objects should be to present the flower in the best possible condition, and with the best possible accessories and surroundings to the eyes of the multitude, or say, to all who are willing to pay a trifling fee for the enjoyment of a gorgeous spectacle. We consider it one of the essential features of a scheme for an exhibition of roses that it shall appeal in some way to the masses of people for support, and prove so attractive and gratifying to the general public as to derive from thence the support needed for its continuance and prosperity. Taking this view of the case, we repeat the statement with which we commenced these remarks, that exhibitions of this sort will decline from their present popularity unless their boundaries are enlarged, and the public are invited to something more than a special exhibition.

In support of the position we take in respect of this subject, it may be proper to observe that special exhibitions have never been successful except in peculiar and exceptional cases. A powerful local influence may sometimes suffice, at other times class interests prevail, but the general public have little sympathy for peculiarities of taste, and will neither be persuaded nor abused into supporting a project which is professedly of an exclusive nature. It is but a few weeks since we directed attention to the threatening decay of the Amateur Tulip Society, and to the extraordinary fact that on the occasion of its last exhibition it was honoured with only one visitor, the rest of the company consisting solely of exhibitors. In some cases it may suffice if cultivators meet and compare their productions, and enjoy a few hours of social intercourse; but if such meetings are intended, the public should not be invited to participate; that which is to be private in fact should be so in theory, and if it is intended to invite the general public to an exhibition, something should be done to render it attractive to persons who have not been schooled to the fine enthusiasm and minute criticism characteristic of the general florist. We hear little of special exhibitions of pansies, auriculas, tulips, and gooseberries; they are too exclusive in character for the public to take any care about them; and so long as the cultivators and connoisseurs of such things are content to hold meetings that are attractive only to persons whose tastes are kindred with their own, there can be no reason for finding fault with them; indeed, we consider such exclusive class meetings to be eminently useful in their way, for the restriction of their objects adds to the earnestness with which those objects are pursued. Nevertheless, in respect of these meetings it will be granted that our postulate is sound—if the public are wanted for their smiles, plaudits, and subscriptions, we must prepare a broad programme, and offer more varied attraction than any one class of exhibition subjects can possibly afford.

Exhibitions of roses are always regarded as feasts open to all comers, and suited to the universal taste. No sane person would openly avow a distaste for roses, but a great many who are reputed to be sane take good care never to pay a shilling to see them. The Crystal Palace can command a company for a rose show, for the holders of season tickets are alone sufficient; but the Crystal Palace Rose Show is less crowded than of yore, and the impartial observer—shall we say, the philosophical observer?—cannot fail to notice that the novelty of the thing has passed away, and that it is gradually dropping into the hands of the florists, and will in time come into their hands completely and exclusively, unless invigorated by the introduction of features tending to render it less exclusive and

restrictive in its purpose. We may point to Birmingham in further illustration. The receipts of money at the doors amounted, we believe, to less than a hundred pounds during the recent magnificent rose show. What shall we do—abuse the people of Birmingham for their lack of taste, or enlarge the programme by admitting other subjects than roses, yet still reserving to these last the leading place and the principal share of our attentions? The first alternative may gratify a passing feeling of anger, but can do no good in the end; the second may result in securing that recognition of the beauty of the rose we are so desirous of promoting, and so may be made subservient to the special purpose we have in view in entertaining the idea of a rose show at all. We advocated the enlargement of the programme of Chrysanthemum shows some years ago, and have now the satisfaction of knowing that the societies who were advised in time have prospered, and that the combination of a show of fruits and miscellaneous plants with chrysanthemums does not detract from the importance of the leading features, but rather enhances it, by rendering the chrysanthemums more attractive by suitable surroundings. We would suggest to the promoters of rose shows that fine-foliaged plants, fruits, and florists' flowers generally can be shown in great variety and the best possible condition at the same time as the roses; and a judicious combination of these several objects, the roses to be the leading feature and main attraction throughout, might prove more attractive than roses alone. And let it not be supposed that it is any degradation of art to consult the tastes of the public, while seeking also to educate those tastes to the appreciation of the highest forms of beauty. The preacher can do no good without an audience; the florist may as well keep his flowers at home as stage them where there are no spectators. It is more reasonable to provide the public with what it wants than with what it does not want; and when support is withheld from any entertainment, we may fairly conclude it is of a kind that does not satisfy a public want; if it did, the public would accept and support it.

CONDITION OF THE CROPS IN THE WEST OF ENGLAND.—Our Somersetshire Correspondent writes as follows:—The apple crop, especially in the lower part of Somersetshire and the borders of Devon, is partial. In some districts they are very thin, but in no instance have I heard of or seen a heavy crop, although there was in every case a wonderful show of bloom. The strawberry crop has been an average one, while all kinds of bush fruits are plentiful. The potato disease has made sad havoc in some isolated districts, having made its appearance quite three weeks earlier than usual; but I am happy to add it did not generally appear thus early. It is, however, to a close observer, showing itself now pretty generally; but as all the early sorts are nearly ripe with us, I do not anticipate any serious loss, except it may be amongst the late kinds. In elevated positions the want of rain has been much felt to assist the pasturage and the turnip crop; and fortunately we have lately had a good fall of rain, and the country has suddenly acquired a new tint of delightful greenness. Travelling a fortnight ago into Devonshire, I noticed large fields with an excellent plant both of mangolds and turnips; but the hay harvest in that district was not more than half over, as I noticed several large breadths still uncut, and still larger breadths to be carried to the ricks. All corn crops are looking most promising; oats on some warm well drained spots are ready to be cut, and only need fine weather. The hay harvest in this part of Somerset is nearly over; the weather has been excellent for such work for the last three weeks, and the crops generally speaking good, although not heavy. A slight storm occurred on July 12, but it did not last long enough—only merely to lay the dust in the district from which I write; but since Sunday we have had a liberal supply, and turnips and grass are growing prodigiously.

MR. B. S. WILLIAMS, OF VICTORIA NURSERY, HOLLOWAY, has been entrusted with the decoration of the Guildhall of the City of London on the occasion of the visit of the Sultan and the Prince of Wales; and also with the decoration of the Agricultural Hall for the Ball in honour of the visit of the Belgian visitors. Our readers will not need to be assured that these undertakings have been carried out with great spirit, and that our numerous visitors will be convinced by what they see that during the reign of St. Swithin, in this dark and changeable clime, we are enabled to produce and preserve some of the noblest forms of exotic vegetation. The palms, cycads, ferns, dracænas, and dasyliorions, which are prominent features of Mr. Williams's magnificent groups of plants, are among the finest the country can produce, and it is a fortunate circumstance that such plants are available to add to the splendour of these receptions.

RIVAL SYSTEMS OF GRAPE-GROWING.—Mr. Cannell, having been assailed from all sides, and occasionally misrepresented, has announced his intention of publishing a pamphlet on the subject. This is judicious, and we are quite sure he will find thousands of purchasers. Since the publication of our remarks on the treatment of the grape-vine by the restrictive and extensive methods, there has been a tedious discussion of a matter which admits of being compressed into a nutshell, and we look forward to the publication of Mr. Cannell's pamphlet as likely to close a paper war with an honourable peace, in which it may become apparent that the contest was not all in vain. Persons desirous of obtaining Mr. Cannell's pamphlet must send stamps to the amount of one shilling for every copy required, to Mr. Bryce, publisher, 47, King Street, Woolwich, Kent.

FRUIT FLAVOURED AT WILL.—A gardener of Gand has, after many trials, succeeded (writes *Galignani*) in giving any kind of fruit the flavour he pleases while it is still on the tree. Let us take an apple, for instance: he pricks it rather deeply in four or five places with a large needle, and then lets it dip for awhile in a bowl containing a liquid possessing the flavour he wishes to communicate. After a few seconds this liquid will have penetrated into the pulp; and this operation being repeated two or three times, at intervals of eight or ten days, the apple is left to ripen on the tree, and will subsequently be found to have acquired the taste either of strawberry, raspberry, cloves, &c., according to the liquid employed. Those who believe this can be done may be expected to believe anything. However, now is the time to put it to the test of experiment; and when we obtain a ripe apple with the flavour of a peach, we will confess that the flavouring of fruit at will is possible. Even then the question will arise, *qui bono?* The time spent in spoiling an apple might possibly be spent in growing a peach. These horticultural wonders usually appear after Parliament has been prorogued: are the editors of newspapers in need of sensations to counteract the wearisomeness of the debates on the Reform Bill?

MISCELLANIES AT THE BIRMINGHAM ROSE SHOW.

Though the roses were the principal attraction, and the foundation of the exhibition, there were many interesting, beautiful, and useful objects of various kinds presented to public notice, garden furniture being the most important of these miscellaneous contributions. A few words upon the subjects which most immediately attracted our attention may be useful to our readers.

Messrs. Mapplebeck and Lowe, of Birmingham, contributed liberally. A pair of huge cast-iron vases from this firm added much to the beauty of the display on the ground floor of the hall; they were of quite simple but bold design, without ornamentation, painted stone colour. Mr. Job Cole, of Birchfields, very generously filled these with roses, and rendered them sumptuous decorations. From the same firm came mowing machines, rollers, watering engines, garden seats and tables, all in the best workmanship, and those that should be elegant really so in every detail of construction and embellishment. The least pretentious, though not the least worthy, of the articles in this collection was the "tubular flower tray," which the judges singled out from a mass of more costly and elaborate articles for commendation. This is a shallow tin tray, made in the fashion of a soup-plate, with small upright tubes set in circles within it. When skilfully filled with flowers it is an elegant table ornament, and, because of its extreme cheapness and simplicity, should be in constant demand.

From Mr. G. Baker, of Chester Street, Aston Road, Birmingham, came an extensive collection of articles of use and ornament in wire-work. On the orchestra platform a rose pavilion, elegantly constructed in a series of arches opening to a central dome, the compartments filled in with trellis-work for the training of climbing roses over the whole exterior of the structure. This the judges highly commended, which was the only mode of marking their special approbation of any object beyond the schedule allowed to them. Had there been prizes offered for such, Mr. Baker's rose pavilion must have come in for a first-class position. From the same a large collection of wire garden chairs, bird-cages, and other useful objects connected more or less with the enjoyments of rural life. The judges selected a peculiarly elegant garden chair, called the "Ne plus Ultra," for special commendation; this might be as appropriately styled "Temptation to Indolence," for the very sight of it makes one feel disposed to rest and be thankful. The arms and back are bent in easy curves exactly to fit the anatomy, so that the metal supports are as easy to the back and shoulders as feather pillows, and the seat is the shape of a prostrate letter *o*, and being of elastic wire yields to pressure as freely and agreeably as an air-cushion.

Messrs. Crichley, Wilde, and Co., of Cannon Street, Birmingham, sent a number of beautiful objects, conspicuous amongst which were some tables suitable for the garden house, breakfast pavilion, entrance hall, or drawing-room. These tables are made of cast-iron and porcelain, or of more costly materials; the designs are extremely elegant, and they are finished to represent bronze or gilded metal, and elaborate coloured marbles. One of these, marked £2 15s., consisted of a beautiful plinth with scrolls in imitation bronze, and a revolving circular top, about 30 inches in diameter, in imitation in-laying of costly marbles. Realities are to be preferred to imitations, but probably real bronze and real inlaying equal in its way to this superb imitation would cost thirty times as much as the price charged in the present instance.

Messrs. Tindall and Maude, of Mansfield, contributed a curiosity, in which elegance and ugliness were combined with singular infelicity, and the result a grotesque illustration of *utile cum dulcè*. This very distinctive object consisted of garden seat and garden roller all in one! The seat, looked at apart from the roller, was elegant and comfortable, but the huge roller, to which the back of the chair served as a handle, and which would be made additionally weighty by wheeling it about while a fat friend took a nap in the chair, made a burlesque of the artist's anxiety to prove himself ingenious. There may be occasions when such a thing would be useful, but at the first glance it suggests that one of Mr. *Punch's* artists has tried his hand at a caricature.

Mr. Thomas Woolley sent a series of most elegant epergnes, vases, and glass bouquet holders. It is impossible to describe these things, and even figures are but a partial aid to the conveyance of correct impressions respecting them. But, seeing many such things in our travels, we must do Mr. Woolley the scant justice of saying that we rarely meet with glass receptacles for flowers better fitted for the purpose than such as he presented to public notice on this occasion. The judges selected a bouquet-holder consisting of a small tube of cut and gilt glass for special commendation, which it well deserved.

DINNER TABLE DECORATIONS, &c.—The schedule properly permitted the use of any kind of foliage, but restricted the selection of flowers to roses only in the competition in dinner table decorations. The first prize in this class was awarded to Miss Evans, of Shrewsbury, for an elegant and rather novel construction, which was admirably finished. The base consisted of a zinc pan, containing earth and planted with *Selaginella*; the exterior rim of this receptacle was finished with a circle of leaves of Irish ivy, firmly fixed on. The stem was formed of wire, and bent in such a way as to represent the stem of a tree, the wire being covered with lichen, and a spray of small-leaved ivy twined around it. The stem was surmounted by a zinc pan, furnished in the same manner as the

base with *Selaginella* and ivy-leaves, but was, of course, smaller in itself and its accompaniments than the base. The flowers were introduced in a manner at once elegant and appropriate to the purpose the ornament was intended to serve. In the pans filled with *Selaginella* small tubes of zinc were inserted, and in these the flowers were placed, with enough water to keep them fresh in a hot room during several hours. The rugged stem and the ivy leaves may suggest to some readers an *outré* degree of rusticity, but there was a peculiar elegance and brightness about the whole affair that rendered it acceptable on its intrinsic merits, and additionally acceptable because a departure from the style that has become almost as fixed for these things as the laws of the Medes and Persians. We sincerely hope that Miss Evans will favour a London company with an example of her style of rustic work for dinner tables; it would give a new direction to those ideas which have become tame through being moulded to a groove, which, in fact, are imitative rather than inventive. Had we been aware so pretty a scheme would appear in this exhibition, we should have adopted measures to secure a sketch for the *MAGAZINE*, but there was no time for anything of the kind in our unprepared condition. The second prize went to Miss Mort, of Stafford; third, Miss Cole, of Birchfields; fourth, Miss Twigg, of Stafford. There was a class for "best design or basket of roses and rose foliage, arranged suitably for entrance hall or room decoration," in which the first award went to Mr. Thomas Lloyd for a bold and showy pyramid of roses well adapted for an entrance hall. In the lengthy and admirably-written report of the show which appears in the *Midland Counties Herald*—a report very different in tone and purport from those miserable penny-a-lining sketches that Mr. William Dean has lately so properly castigated—it is remarked that the award must have been made because of the absence of design, but this was not the case; the stipulation of adaptiveness for "entrance hall" took the competition out of the category of table elegancies, and this big pyramid, all a-glow with circles of fresh roses set between circles of green leaves, would look well in almost any entrance or on any sideboard, but for the table it was unsuitable, being destitute of design and grace. The second prize went to Mr. Vertegans for a pretty basket of roses, good enough for the table, but not showy enough for a hall; in fact, if placed upon a hall-table or sideboard, it would suggest the idea that a visitor had left it there by accident, or to be called for again, or that it was to be sent away presently as a gift to a friend. The terms of schedules must never be forgotten, and perhaps this part of the schedule might be improved. An improvement in it might perhaps be accomplished by removing the restriction as to foliage, for the leaves of roses are not well adapted for designs in which it is sought to incorporate distinct and elegant features. Third, Mr. Cole; fourth, Miss Mort. In another class for vases with roses and rose-foliage Mr. Cole was first, Mr. Vertegans second.

BOUQUETS suitable for the hand were as usual too large and too elaborate. Yet there were many extremely beautiful bouquets of the orthodox pattern, the flowers packed firmly together in a hemispherical mass. Mr. Job Cole's was undoubtedly the best, and had the first place, Miss Mort second, Mr. Cranston third, Mr. Vertegans fourth. In one of these we noticed a bloom of the old Austrian copper rose, shining like a new coin of the "red, red gold." Mr. Cranston's bouquet was extra large in size, and fit for the hand of a giantess in process of exhibition at a fair, and it consisted of half open buds of teas and noisettes of most exquisite beauty, all of them pale yellow or white, or blush, the very absence of colour increasing rather than detracting from its uniqueness. As a bouquet it was almost nowhere, but as a bunch of rose-buds it was as rich as cream and honey combined. Probably it was placed there just to show what the King's Acre Nurseries could do in the delicate way, and with none of the colour that made the 72 from the same place so glowing and glorious. Oh that some genius would step into the ranks of the exhibitors of bouquets, and give us something new—say half a dozen flowers instead of fifty, a few sprigs of elegant leafage or grasses to make a green or purplish haze amongst the colours, and perhaps a leaf (or leaves) of some sort in place of the perforated paper, a leaf suitable to embrace the whole, and finish it with a boundary rim of colour! We may here, perhaps, most properly notice two beautiful contributions. Miss Johnson sent a basket filled with paper roses that no one could distinguish from real roses without touching them. They had this peculiar merit that they were portraits of varieties, and comprised *Gloire de Dijon*, *Rev. R. Hole*, *Madame Falcot*, *Blairi No. 2*, *Jules Margottin*, and one or two more. This was art imitative, and beyond such imitation we believe art cannot make another step. Miss Brewer sent a case of dried ferns, arranged in a mass on a flat surface, with a glass to cover them like a picture. In all their lineaments and colours they were perfect, and the arrangement was such that every one was seen in its true character, adding to the beauty of all the rest. This was a most elegant group.

VERBENAS.—There were two fine stands of verbenas for which no prizes could be awarded, but which were highly commended. Messrs. Perkins sent *Warrior*, *Geant des Batailles*, *Blanche de Castile*, *Lord Leigh*, *Magnificans*, *Grand Eastern*, *Beauty of England*, *L'Avénir de Ballant*, *Exquisite*, *Firefly*, *Fairy*, *Ida*, *Lord Houghton*, *Indispensable*, *Abundance*, *Annie Schurer*, *Attraction 1867*, *Henrietta*, a good white; *Cato*, *Attraction 1865*, *Majolica*, *Monsieur Jonteau*, superb deep cobalt blue; *Madame Hardy*, *Black Prince*. C. J. Perry, Esq., of Castle Bromwich, sent a splendid collection of his own varieties of past years, with a few of 1867. Amongst the latter were *Samuel Morton*, *Madame Tonnetier*, *Miss Turner*, *James Birbeck*, and *Sunbeam*, all of them novel, distinct, superb in form, and every necessary of quality of first-class show flowers, but not now to be described, because they are to be dealt with in another manner, and we must avoid as far as possible repetitions.

FINAL GATHERINGS.—Mr. C. Turner, of Slough, sent a box of *Miss Ingram*, but the judges were compelled to pass it by on account of the shabby condition of the flowers by travel. But the stout petals, the beautiful globular form, and the delicate colouring, were all preserved for eyes that could see, and we are glad the amateurs of Birmingham were afforded an opportunity of judging for themselves as to the place this beautiful rose is likely to take in future competitions. Mr. Watson of St. Albans sent two of his new tricolor-leaved geraniums, *Miss Watson* and *Mrs. Dix*, but the last named only was considered worthy of a certificate, and obtained the highest distinction of the kind that could be awarded. Miss Watson appeared to lack colour, whether owing to the same plants having been over-much exhibited, or for what other reason we do not know, but certainly it did not make so favourable an impression as on former occasions this and last season. We wind up this report with a thankful recognition of the service rendered by Mr. Job Cole, nurseryman,

of Birchfields, who grow the collection of white-leaved acers and maize plants for the tables, and rendered many other services equally valuable and original. It was an act of patriotism and self-sacrifice of no small importance, and was rendered additionally appreciable because, although he had done so much, and had removed himself almost entirely out of the competition, and had nothing to gain by it in prizes, he nevertheless kept his name out of sight, and made no excoise of the occasion for advertising himself. Not that we blame a tradesman for putting his name on his goods at an exhibition; it is not only just to himself, but frequently of the greatest service to the public; but when the work is so nobly done, and no praise and no trade is sought thereby, we can believe that it was done for the advancement of art and the good of the town, and we gladly finish with honourable mention of Mr. Cole's name, as we commenced with praise of his decorative plants.

S. H.

THE MOST BEAUTIFUL WILD FLOWERS: WHERE TO GATHER AND HOW TO CULTIVATE THEM.

THE IVY-LEAVED CYCLAMEN, or the common Cyclamen (*Cyclamen hederacefolium*), a native of Southern Europe, but not supposed to be truly British, has been found in several places, apparently wild, and as such is generally included among British plants. Being a very beautiful one, it is in all respects worthy of a place. You cannot, in all probability, find it wild in England, but it is not difficult to obtain, and a lovely plant it is when seen in flower. A ring of it planted round a small bed of choice shrubs forms a beautiful sight. I am not certain that it would do so well about London as in the western and the southern parts of the country, but it is everywhere worth trying. Like those of all the Cyclamens, the flowers are singularly pretty, and being densely produced in low masses, both in rosy purple and pure white, they are invaluable ornaments to the autumnal garden, though very seldom grown. The Water Violet (*Hottonia palustris*), which bears such handsome whorls of pale purple flowers, sent up on its erect stems from its leafy dissected leaves submerged under the water, is a choice plant for a fountain-bed or such like. Though usually supposed to grow under water, I have seen quantities of it growing on soft mud-banks, left dry by the water no doubt, and probably flooded a few weeks after; but I never saw the plant half so luxuriant as on those mud-banks, which were darkly and richly green with its dense cushion of rosettes of leaves, always straggling when in the water, and I regretted much that I had not the pleasure to see such healthy spreads of the water violet in full beauty. There is no doubt, then, that it may be grown on soft muddy spots as well as in water. To grow it in a fountain-bed, or such position, the best way would be to plant it in a pot, and place it so that its rim was an inch or two below the water. The Money-worts, or *Lysimachias*, are sufficiently ornamental for cultivation; *Nummularia* being the Creeping Jenny of the London streets, and a most useful plant it is for that purpose, trailing its luxuriant leaves where few other plants would be so well content. The upright-growing species *L. thyrsoflora* is very desirable for the margin of water, in consequence of the curious way it has of hiding its flowers in among the green of its leaves. A mass of it by a river or pond or ditch looks very distinct and pleasing. Finally, we have in the Primula order the beautiful *Trialialis* of the north, a wood plant, and somewhat difficult to cultivate, but one that is frequently gathered for that purpose.

Of the Thrift family, certainly the most valuable plant is a deep and charming rose variety of the common Thrift (*Armeria vulgaris*). Everybody knows the Thrift of our sea-shores, and of the tops of some of the Scotch mountains, with its pale pink flowers; but the variety I allude to is of a deep and showy rose, and one of the sweetest things you can employ in the spring garden as an edging plant, or as clumps here and there in borders. This kind is sold and known as *Armeria vulgaris rubra* or *A. rubra*. The common kind is not worth growing beside it, but the white variety is. Any of the British Statice that may be collected are worthy a place in a collection of wild flowers. In the Goosefoot and Dock order, *Atriplex portulacoides* and *Polygonum bistorta* will be found the best. The first is a silvery-looking shrubby herb, frequent on the sea-shores; the second a showy herb, most plentiful in the north. *Euphorbia Lathyris* is the distinct-looking and handsome Capser Spurge, which is established here and there among us; it is worthy of a place, though not for the beauty of its flowers. Nor must we forget the common Hop, *Humulus lupulus*, which I need hardly say is very ornamental when well developed over a bower, or in any other position where it may have an opportunity to become finely developed. The beautiful Pheasant's Eye or "poet's Narcissus," *Narcissus poetica*, hawked about the streets of London so abundantly in spring, is generally included among native plants, though not considered truly British; but whether it be so or not, such a distinctly beautiful plant should be in every garden. The Snowflake (*Leucojum aestivum*) occurs in several of the south-eastern counties, and makes a handsome border bulb; the dwarf, sweet, and fine vernal Snowflake has been recently found in Dorsetshire in some abundance; while the common Snowdrop is perfectly naturalized in various parts of the country. These, it need hardly be said, should all be in any living collection of British wild flowers,

and with them the Daffodil and the Wood-tulip (*T. sylvestris*). This last is found most frequently in some of the eastern counties of England, but may be had readily from the nurserymen, who sell it as *T. florentina* and *cornuta*. *Lloydia serotina* is an extremely rare and pretty little bulbous plant, found in North Wales, but scarcely obtainable, I fear, by any of your readers. It is also known as *Anthericum serotinum*.

A Gladiolus (*G. communis*) has recently been found in the New Forest, near Lyndhurst; it is worthy of culture, and indeed is, or was, a favourite plant in many gardens before it was discovered as a British plant, having been brought to England in old times to our gardens from central and southern Europe. The spring Crocus (*C. vernus*) is abundant in the neighbourhood of Nottingham, and other parts of England and Ireland; and the less known but equally beautiful autumn Crocus (*C. nudiflorus*) is also naturalized in Derbyshire, about Nottingham, and in a few other places. It is quite needless to praise either. The blue or normal form of the vernal crocus is, or ought to be, in nearly every garden; but the autumnal crocus is quite of rare occurrence in gardens, and should be introduced to all, because it opens its handsome flowers when most others are perished or perishing, and closes the season of flowers so well opened by the spring crocus. Equally easy of culture with the spring crocus, but, being so much scarcer, deserves to have a good position, good soil, and some watchfulness, to prevent its being dug up by careless workmen, that it may increase, and become a conspicuous autumnal ornament in our gardens.

We will next go with the reader to the margin of the cool water, for it is warm and pleasant, and a chat about hardy water plants will not be sufficient to cause the reader to shiver. The embellishment of the margin of a bit of water is really much more of an important subject than is generally supposed. It is true that by following the directions of the garden books, or even the best examples that we see of water in our public gardens, nothing to boast of can be done, but nevertheless, by a tasteful selection of really good and hardy water plants, and above all a judicious disposition of them, a great deal of exquisite beauty may be produced. Hitherto this thing has been very badly performed by the designers of pieces of water, or by those who plant the margins of such. Usually you see the same monotonous vegetation all round the margin if the soil be rich; in some cases, where the bottom is of gravel, there is little or no vegetation, but an unbroken ugly line of washed earth between wind and water. In others aquatics accumulate till they are a nuisance and an eyesore; and I do not simply mean the below-surface weeds, like the *Anacharis*, but the white lily when it gets too profuse. Now a well developed plant, or group of plants, of the queenly Water Lily, floating its large leaves and noble flowers, is an object not surpassed by any other plant in our gardens; but when it increases and runs over the whole or a large part of a piece of water, and thickens together, and the fowl can't make their way through in consequence, then even the queen of British water plants becomes a nuisance. No garden water, however, should be without a few fine plants or groups of the water lily, and if the bottom did not allow of the free development of the plant, a lot of scrapings or rubbish might be accumulated in the spot where it was desired to exhibit the beauties of *Nymphaea*, and thus arranged it could not spread too much. But it is not difficult to prevent the plant from spreading; indeed, we have known isolated plants and groups of it remain of almost the same size for years, and where it increased too much, reducing to the desired limits is of very easy accomplishment, either by cutting off the leaves or by getting at the roots in the bottom. The yellow water lily, though not so beautiful as the preceding, is worthy of a place; and also the little *Nuphar pumila*, a variety or sub-species found in the lakes of the north of Scotland, if you can get it. In collecting those things, the true and the only way is to get as many as possible from ordinary sources at first, and then exchange with others having collections, whether they be the curators of botanic gardens or private gentlemen fond of interesting plants. With a little perseverance every good thing may soon be collected in this way.

One of the prettiest effects I have ever observed was afforded by a sheet of *Villarsia nymphoides* belting round the margin of a lake near a woody recess, and before it, more towards the deep water, a fine group of water lilies. The beauty of this *Villarsia* is very insufficiently developed in garden waters. It is a charming little water plant, with its nymphæa-like leaves and numerous golden yellow flowers, which furnish a charming effect on fine days when the sun is "out." It is not very commonly distributed as a native plant, though where found generally very plentiful, and not difficult to obtain in gardens where aquatics are grown. It is in all respects one of the most serviceable of hardy water plants.

Not rare—growing, in fact, in nearly all districts of Britain—but exquisitely beautiful and singular, is the Buckbean or Marsh Trefoil, with its flowers elegantly and singularly fringed on the inside with white filaments, and the round unopened buds polished on the top with a rosy red like that of an apple blossom. In early summer,

when seen trailing in the soft ground near the margin of a stream, this plant has more charms for us than any other, and we take care to have an abundance of it. It will grow in a bog or any moist place, or by the margin of any water. Though a rather frequent native plant, it is not half sufficiently grown in garden waters; but, indeed, these are invariably neglected.

If you have ever seen the flowering rush (*Butomus umbellatus*) in flower, you are not likely to omit it from a collection of water plants, as it is conspicuous and distinct. It is a native of the greater part of Europe and Russian Asia, and dispersed over the central and southern parts of England and Ireland. Plant not far from the margin; it likes rich muddy soil. The common *Sagittaria*, prevalent, very prevalent in England and Ireland, but not in Scotland, might be associated with this; but there is a very much finer double exotic kind to be had here and there, and which, though not British, I must name here. It is really a fine plant, its flowers being white, and resembling, but larger than, those of the old white double rocket. It grows in abundance in the tea or pleasure gardens of the Rye House at Broxbourne, where it fills a sort of oblong basin or wide ditch, and looks quite attractive when in flower. It has a peculiarity of forming large tubers, or rather receptacles of farina, and I have found that in searching for these that ducks, or something of the kind, have destroyed the plants.

Among bold and picturesque plants for the water-side, nothing equals the great Water-dock (*Rumex hydrolapathum*), which is rather generally dispersed over the British isles, has leaves quite sub-tropical in aspect and size, becoming of a lurid red in the autumn. It forms a grand mass of foliage on rich muddy banks. The Bulrushes must not be omitted, but they should not be allowed to run everywhere. The narrow-leaved one is more graceful than the common one. *Carex pendula* is very fine for the margins of water, its elegant drooping spikes being quite distinct in their way. It is rather common in England, more so than *Carex pseudo-cyperus*, which grows well in a foot or two of water, or on the margin of a muddy pond. *Carex paniculata* forms a strong and thick stem, sometimes three or four feet high, somewhat like a tree-fern, and with luxuriant masses of falling leaves, and on that account is transferred to moist places in gardens and cultivated by some, though generally those large specimens are difficult to remove and soon perish. *Scirpus lacustris* (the "Bulrush") is too distinct a plant to be omitted, as its stems, sometimes attaining a height of more than seven and even eight feet, look very imposing; and *Cyperus longus* is also a desirable thing, reminding one of the aspect of the Papyrus when in flower. It is found in some of the southern countries of England. *Cladium mariscus* is also another distinct and rather scarce British aquatic which is worth a place.

As for the ferns, it is needless to mention them, considering the immense attention that has been paid them of late years. Whole nurseries are now almost exclusively devoted to the production of British ferns and their varieties. My object is to encourage the culture of things that are comparatively neglected, and however graceful and beautiful ferns may be, and however indispensable the fernery, as an adjunct to the flower-garden, your readers have but to attempt the culture of the handsome British flowering plants, combined, if the cultivator so desires it, with the best alpine, spring flowers, and herbaceous plants of all countries, to find infinitely more enjoyment therefrom than ferns are capable of affording.

But though ferns are not in need of a good character, their allies the Equisetums are, some of them being of graceful and distinct habit. One of the most strikingly distinct and elegant plants in the Oxford Botanic Garden grows profusely along by the wall, in the shady fern border, in that very old and most interesting botanic garden. It is the British *Equisetum Telmateia*, or "Great Equisetum," which grows pretty commonly in the greater part of England and Ireland, attaining its greatest development in rich soil and in shady spots. It there attains a height of three or four feet, and the numbers of slender branches depending from each whorl look most graceful. It should be planted in a shady place, near water if convenient, but it thrives famously in deep moist soil, in any position in a garden where ferns thrive, and as it associates well with them, in or near the fernery will be found a good position for it. The wood Equisetum (*E. sylvaticum*) common all over Britain, is considerably smaller than the preceding, but even more graceful; indeed, sufficiently so to warrant its being grown in pots, though it thrives well in any shady moist position. The long simple stemmed Equisetums, or Horse-tails, also interesting to cultivate in wet or marshy spots, or by the sides of water, but not so graceful or ornamental as the species above named, which are as well worth growing in a garden as the costliest productions of tropical climes, which entail endless work and a perpetual cost to retain.

CYPRIPEDIUM CALCEOLUS.

ANNUAL REPORT ON STRAWBERRIES, 1867.

Notwithstanding the severe frost of the 23rd, 24th, & 25th of May last, the strawberry crop has been better than the anticipations of cultivators, who saw their promise of a crop well-nigh ruined by that unseasonable weather. True, in some few cases it was more severe than generally, and in those instances rendered the crop nearly useless, on account of the deformity of the fruit. But, as a rule, many have been agreeably disappointed in seeing a fair average crop where they expected none. I know from my own observation that some gardeners had, after the frost of the above date, given up all idea of getting any fruit, and had therefore not attempted to put down the usual mulchings to keep the fruit clean. Happily some ten days' more experience brought with it more cheering prospects, for although many of the first flowers were killed, the after flowers showed very promising, and in the majority of cases a good crop has been obtained. The most unsatisfactory cases which I have seen have been in those places where the frost was less severe, where the flowers were injured but not killed. The production of deformed fruit in these cases seems to point to some disturbance of the generative functions by an excessively low temperature, the result being imperfect fertilization of the stigma and imperfect progeny. I suppose deformities and monsters generally, in both the animal and vegetable kingdoms, are the consequence usually of defective impregnation. But I leave the further consideration of this subject to others, content with having called attention to the fact that deformed strawberries have been more than ordinarily abundant this season.
